Neutron Deficient Isotopes of Iodine*

LUIS MARQUEZ AND I. PERLMAN Radiation Laboratory and Department of Chemistry, University of California, Berkeley, California (Received January 13, 1950)

The iodine isotopes I¹²³, I¹²¹, I¹²¹, and I¹²⁰(?) have been made by bombarding antimony with α -particles. Their characteristics are summarized and evidence for mass assignments presented.

URING the course of some investigations of abnormal change in nuclear charge following irradiation with high energy particles, some of the nuclides encountered proved to be light isotopes of iodine which had not been reported previously. The main study will be reported at a later date while the present communication describes some work done to characterize and identify the iodine isotopes. The mass number region of interest is that below I¹²⁴ as higher isotopes are well known.¹

Four new isotopes of iodine have been identified with mass assignments and decay characteristics as indicated in Table I. The method of making mass assignments for some of these was to compare shapes of excitation curves of (α, xn) reactions on antimony in which known iodine activities were produced from Sb¹²³ and the new ones to be assigned from Sb¹²¹. The excitation functions as shown in Fig. 1 are fairly crude as the only objective was to compare shapes in order to assign mass numbers. The experimental procedure was to irradiate antimony (57 percent Sb¹²¹, 43 percent Sb¹²³) with helium ions of different energies, to isolate the iodine by a method in which the chemical yield could be measured, and then to resolve the iodine decay curves into the several components making use of distinctive radioactive properties.

13-HR. I123

A 13-hr. component was assigned to I123 since its excitation function paralleled that for 56-day I¹²⁵, both curves being of the shape that would be expected for $(\alpha, 2n)$ reactions; in this case, on Sb¹²¹ and Sb¹²³, respectively. The yields as shown include corrections for natural abundances of Sb¹²¹ and Sb¹²³, and are based on the assumption that both the 13-hr. I^{123} and 56-day I^{125} have one K x-ray per disintegration, and assuming one percent counting efficiency in the argon-filled Geiger tubes. The 13-hr. I¹²³ has conversion electrons of 150 ± 15 kev energy as determined with a low resolution beta-ray spectrometer and by absorption in beryllium. Gamma-rays corresponding to this energy were also observed. This activity with similar half-life and radiation characteristics has been reported recently by Mitchell, Mei, Maienschein, and Peacock.²

4.5-DAY I124 AND 13-DAY I126

The curves for both of these isotopes using normal antimony as a target are shown as appropriately labeled solid curves in Fig. 1. The curve for I¹²⁶ is characteristic of an (α, n) reaction as is the low energy part of that for I¹²⁴. The upswing beyond 30 Mev in the I¹²⁴ curve is due to the $(\alpha, 3n)$ reaction on Sb¹²³. The points shown for the broken-line projection of the I¹²⁴ curve were obtained from the irradiation of separated[†] Sb¹²¹ from which I^{124} can be formed only by the (α, n) reaction.

TABLE I. Radioactivity of the isotopes of iodine.

Mass No.	Half-life	Radiation	Energy
124 123 122 121 120?	4.5 days 13 hr. 4 min. 1.8 hr. ~30 min.	K, β^+ K, γ, e^- $\beta^+(K, \gamma?)$ K, β^+, γ, e^- $\beta^+, \gamma(K?)$	$\beta^+=2.1\pm0.1 \text{ Mev}$ $e^-=150\pm15 \text{ kev}$ $\beta^+=2.9\pm0.1 \text{ Mev}$ $e^-=185\pm10 \text{ kev}$ $\beta^+=1.2\pm0.1 \text{ Mev}$ $\beta^+=4.0\pm0.2 \text{ Mev}$

² Mitchell, Mei, Maienschein, and Peacock, Phys. Rev. 76, 1450 (1949).

[†] The sample of separated antimony consisting of 99.3 percent Sb¹²¹, 0.7 percent Sb¹²² was obtained from the Isotopes Division of the U.S. AEC.

^{*} This work was performed under the auspices of the AEC. ¹ For summary of data see G. T. Seaborg and I. Perlman, Rev. Mod. Phys. **20**, 585 (1948).

FIG. 1. Excitation functions for (α, xn) reactions on antimony.

The discrepancy in yields at 20 Mev between I126 and I¹²⁴ is not explained; but it may be remarked that in other cases such as the fission of bismuth³ and the (γ, n) reaction on iodine,⁴ the measured yield of I¹²⁶ has been much lower than expected, making it appear that not all of the decay events take place through the 1-Mev beta-particle upon which the yields are based.

The half-life of I¹²⁴ was measured as 4.5 days and the β^+ -energy as 2.1 \pm 0.1 Mev. It is estimated from the yield of K x-rays that this isotope decays only about 30 percent by positron-emission and 70 percent by electron-capture.

⁴ M. L. Perlman, Phys. Rev. 75, 988 (1949).

4-MIN. I122

In experiments in which an hour was consumed in chemical separation, no activity appeared which followed the excitation function of that part of the 4.5-day I¹²⁴ curve produced by the $(\alpha, 3n)$ reaction. It was therefore assumed that I^{122} , which would be formed by the $Sb^{121}(\alpha, 3n)I^{122}$ reaction, is short-lived. More rapid chemistry showed a 4-min. iodine activity, and a single yield determination at 45 Mev showed it to be in the expected range as indicated in Fig. 1. The positron has an energy of 2.9 ± 0.1 Mev, and it is estimated that there is some electron-capture branching.

The assignment of this activity to I122 is also based on the fact that it was the only new activity beyond I^{123} . I¹²⁴, I¹²⁵, and I¹²⁶ to appear at 45 Mev. A 1.8-hr. activity assigned to I¹²¹ (from α , 4*n* reaction) did not appear at this energy.

1.8-HR. I¹²¹

An activity with 1.8-hr. half-life with a 1.2-Mev positron and conversion electrons of 185 kev appeared in irradiation of antimony with 60-, 100-, and 360-Mev helium ions. Its decay is followed by the appearance of 17-day Te¹²¹ in approximately the proper yield for a parent-daughter relationship.

30-MIN. I¹²⁰(?)

In the higher energy irradiations (100 and 360 Mev) a 30-min. activity appeared, having a hard positron of 4.0 Mev. The decay of the iodine containing this activity was followed by the appearance of a tellurium activity which could not be resolved uniquely but which does have a half-life of several days. It is possible that this activity is 4.5-day Te¹¹⁹. This would indicate that I¹¹⁹ was present. However, the observed positron energy of the 30-min. period is in better agreement with the prediction for I¹²⁰ which may mean that I¹¹⁹ was also present but unobserved.

We wish to thank Dr. J. G. Hamilton and the staff of the Crocker Laboratory cyclotron and Mr. James Vale and the group operating the 184-inch cyclotron for the irradiations used in these studies. We also wish to acknowledge the contribution to some of the early phases of this work by Dr. M. Lindner now at the State College of Washington, Pullman, Washington.
