(Received 13 June 2020; accepted 4 August 2020; published 25 August 2020)

We report an investigation of the self-energy screening effects for the g factor of the ground state of Li-like ions. The leading screening contribution of the relative order 1/Z is calculated to all orders in the binding nuclear strength parameter $Z\alpha$ (where Z is the nuclear charge number and α is the fine-structure constant). We also extend the known results for the $Z\alpha$ expansion of the QED screening correction by deriving the leading logarithmic contribution of order $\alpha^5 \ln \alpha$ and obtaining approximate results for the α^5 and α^6 contributions. The comparison of the two approaches yields a stringent check of consistency of the two calculations and allows us to obtain improved estimations of the higher-order screening effects.

DOI: 10.1103/PhysRevA.102.022815

I. INTRODUCTION

Measurements of the bound-electron g factor in light H-like ions have recently reached the fractional accuracy of few parts in 10^{-11} [1–3]. In a combination with advanced theoretical calculations, these measurements provided the most accurate determination of the electron mass as well as one of the best tests of the bound-state quantum electrodynamic (QED) theory. Extensions of these tests towards heavier H-like ions are anticipated in the future [4]. The main obstacle for such extensions is presently on the theory side, caused by the insufficiently known two-loop QED effects [5–7].

Accurate experiments were performed also on the g factors of Li-like ions [8–10]. They provided sensitive tests of the QED theory of the electron-correlation and relativistic nuclear recoil effects, probing QED beyond the external-field approximation. Recently, the experiments were extended further to B-like ions [11], providing the first g-factor measurement for the nonzero orbital angular-momentum states. In future, a combination of the g-factor measurements in different charge states of the same element has a potential to provide an independent determination of the fine-structure constant α [12,13].

To match the experimental precision, theoretical investigations of atomic g factors should be performed to all orders in the nuclear binding strength constant $Z\alpha$ (where Z is the nuclear charge number and α is the fine-structure constant). Such calculations are often very demanding and require taking

into consideration numerous effects [14,15]. A number of highly sophisticated calculations were performed during the past decade, most notably, the calculations of the self-energy and vacuum-polarization screening corrections [16,17], the two-photon exchange correction [18], and the nuclear recoil effect [19]. Despite the achieved progress, further investigations are needed in order to match the experimental precision for light Li-like ions.

In calculations performed to all orders in $Z\alpha$, the electron-electron interaction is accounted for by perturbation theory, with the expansion parameter 1/Z. The leading term of this expansion $\propto 1/Z^0$ corresponds to the hydrogenic approximation, i.e., the approximation of noninteracting electrons. The higher-order terms $\propto 1/Z^1$, $1/Z^2$, etc. are induced by the electron-electron interaction. The modification of the hydrogenic corrections by the electron-electron interaction is often referred to as the screening effect. In the present work we investigate the effect of the screening of the QED corrections, which presently induces one of the largest uncertainties in the theoretical predictions of g factors of light Li-like ions [10,20].

First calculations of the QED screening effect [21,22] included only the leading term of the $Z\alpha$ expansion and were applicable just for the lightest ions. The forthcoming investigations [15,23,24] approximately included contributions of higher orders in $Z\alpha$, but the accuracy of these approximation was rather low, leading to errors of the screening effects $\approx 10\%$ for medium-Z ions.

The first full-scale QED calculation of the self-energy and vacuum-polarization screening effects was accomplished in Refs. [16,17]. These calculations accounted for the leading screening corrections of the relative order $\propto 1/Z$ rigorously and the higher-order effects $\propto 1/Z^{2+}$ approximately. Still, the numerical uncertainty of these calculations $\approx 1\%-2\%$ was not sufficient for matching the experimental precision in the low-Z region. Moreover, the results were reported only for

four ions, thus not allowing to perform a consistency check between the all-order and the $Z\alpha$ -expansion calculations.

The main goal of the present work is to perform an independent calculation of the self-energy screening correction for the g factor of the ground state of Li-like ions. We aim to cross-check the previously publishes results, to improve the numerical accuracy, and to perform a detailed analysis of consistency of the all-order numerical approach against the $Z\alpha$ -expansion calculations. To achieve this, we extend the existing $Z\alpha$ -expansion results by deriving the leading logarithmic contribution of order $\alpha^5 \ln \alpha$ and obtaining approximate results for the α^5 and α^6 contributions. Combining the two methods, we obtain improved estimations for the higher-order screening effects $\propto 1/Z^{2+}$ and increase the accuracy of the theoretical description of the QED screening effects in light Li-like ions.

The relativistic units $(\hbar = c = m = 1)$ and the Heaviside charge units $(\alpha = e^2/4\pi, e < 0)$ will be used throughout this paper.

II. g FACTOR

The linear Zeeman shift of the energy of an atomic state v can be written as

$$\delta E_v = g\mu_0 B\mu_v,\tag{1}$$

where $\mu_0 = |e|/(2m)$ is the Bohr magneton, B = |B| is the external magnetic field, g is the g factor of the atomic state, and μ_v is the angular-momentum projection on the direction of the magnetic field. In the present work we assume that the nucleus has zero spin, so that all interaction with the magnetic field comes from the electrons.

The relativistic interaction of an electron with the magnetic field is represented by an operator

$$V_{\text{mag}}(\mathbf{r}) = -e\boldsymbol{\alpha} \cdot \mathbf{A}(\mathbf{r}) = \frac{|e|}{2} B(\mathbf{r} \times \boldsymbol{\alpha})_z, \tag{2}$$

where $A(r) = (B \times r)/2$ is the vector potential and we choose the z axis to be directed along **B**. Expressing the energy shift caused by V_{magn} in terms of the g factor and fixing the angular-momentum projection of the atomic state as $\mu_v = 1/2$, we introduce the effective operator responsible for the g factor as

$$V_{g} = 2(\mathbf{r} \times \boldsymbol{\alpha})_{z}. \tag{3}$$

The matrix element of the operator V_g between two Dirac wave functions is evaluated as

$$\langle n_1 | V_g | n_2 \rangle = (-1)^{j_1 - \mu_1} C_{j_2 \mu_2, j_1 - \mu_1}^{10} P(n_1 n_2),$$
 (4)

where j and μ are the total angular momentum and its projection, respectively, $C^{jm}_{j_1\mu_1,j_2\mu_2}$ is the Clebsch-Gordan coefficient, and the radial integral P is given by

$$P(n_1 n_2) = 2 \frac{-\kappa_1 - \kappa_2}{\sqrt{3}} C_1(-\kappa_2, \kappa_1)$$

$$\times \int_0^\infty dr r^3 [g_{n_1}(r) f_{n_2}(r) + f_{n_1}(r) g_{n_2}(r)]. \quad (5)$$

Here, κ is the relativistic angular-momentum quantum number, $C_L(\kappa_a, \kappa_b)$ is the reduced matrix element of the normalized spherical harmonics [see, e.g., Eq. (C10) of Ref. [25]],

and g(r) and f(r) are the upper and the lower radial components of the Dirac wave function defined as in Ref. [25].

For the point-like nucleus, the diagonal matrix element of V_g with hydrogenic Dirac wave functions can be evaluated analytically as

$$\langle v|V_g|v\rangle = \frac{\kappa_v}{2j_v(j_v+1)} \left(2\kappa_v \frac{\varepsilon_v}{m} - 1\right),\tag{6}$$

where ε_v is the Dirac energy. In particular, for the case relevant for this work of v being the 2s state,

$$\langle 2s|V_g|2s\rangle = \frac{2}{3}(\sqrt{2\gamma + 2} + 1),$$
 (7)

where $\gamma = [1 - (Z\alpha)^2]^{1/2}$.

III. GENERAL FORMULAS

We now turn to the general formulas describing the self-energy screening correction to the g factor of a Li-like ion. We will assume that the electronic configuration has the form of one valence electron state (denoted by v) over a closed shell of core electron states (denoted by c). The derivation of the formulas was first presented in Ref. [17] within the formalism of the two-time Green's function method [26]. In the present work, we will reformulate this problem in order to suit our calculational approach.

We start by introducing two operators which will be building blocks in the following formulas. The first one is the electron-electron interaction operator $I(\omega)$, defined as

$$I(\omega, \mathbf{r}_1, \mathbf{r}_2) = e^2 \alpha_1^{\mu} \alpha_2^{\nu} D_{\mu\nu}(\omega, \mathbf{r}_{12}), \tag{8}$$

where $\alpha^{\mu} = (1, \alpha)$ are the Dirac matrices, $\mathbf{r}_{12} = \mathbf{r}_1 - \mathbf{r}_2$, and $D_{\mu\nu}(\omega, \mathbf{r}_{12})$ is the photon propagator. In the present work we use the Feynman gauge, in which the photon propagator takes the simplest form,

$$D_{\mu\nu}(\omega, \mathbf{r}_{12}) = g_{\mu\nu} \frac{e^{i\sqrt{\omega^2 + i\epsilon}r_{12}}}{4\pi r_{12}},\tag{9}$$

where $r_{12} = |\mathbf{r}_{12}|$ and ϵ is a positive infinitesimal addition.

The one-loop self-energy (SE) operator $\Sigma(\varepsilon)$ is defined by its matrix elements with the one-electron wave functions $|a\rangle$ and $|b\rangle$,

$$\langle a|\Sigma(\varepsilon)|b\rangle = \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \sum_{n} \frac{\langle an|I(\omega)|nb\rangle}{\varepsilon - \omega - u\varepsilon_{n}},$$
 (10)

where the sum over n is carried out over the complete spectrum of the Dirac equation (implying the summation over the discrete part of the spectrum and the integration over the continuum part of the spectrum) and $u = 1 - i\epsilon$.

We split the total self-energy screening correction into four parts as

$$\Delta g_{\text{sescr}} = \Delta g_{\text{po}} + \Delta g_{\text{vr.Zee}} + \Delta g_{\text{vr.scr}} + \Delta g_{\text{dvr}}, \tag{11}$$

with the individual contributions defined in the remainder of this section.

A. Perturbed-orbital self-energy contribution

The perturbed-orbital SE contribution incorporates all terms that can be expressed as matrix elements of the one-loop SE operator $\Sigma(\varepsilon)$. It can be represented as a sum of two parts,

$$\Delta g_{\rm po} = \Delta g_{\rm po1} + \Delta g_{\rm po2},\tag{12}$$

where the first part contains matrix elements of the SE operator with a perturbed wave functions on one side, whereas the second term has perturbed wave functions on both sides. The first term can be expressed as

$$\Delta g_{\text{pol}} = 2\langle v | \Sigma(\varepsilon_v) | \delta_{\text{pol}} v \rangle + 2\langle c | \Sigma(\varepsilon_c) | \delta_{\text{pol}} c \rangle, \tag{13}$$

where

$$|\delta_{\text{pol}}v\rangle \equiv \delta|vcvc\rangle - \delta|vccv\rangle, \quad |\delta_{\text{pol}}c\rangle \equiv \delta|cvcv\rangle - \delta|cvvc\rangle,$$
(14)

and

$$\delta|abcd\rangle = \sum_{\mu_{core}} \left\{ \sum_{n_{1}n_{2}} \left[\frac{|n_{1}\rangle\langle n_{1}|V_{g}|n_{2}\rangle\langle n_{2}b|I(\Delta_{db})|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{a} - \varepsilon_{n_{2}})} + \frac{|n_{1}\rangle\langle n_{1}b|I(\Delta_{db})|n_{2}d\rangle\langle n_{2}|V_{g}|c\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{c} - \varepsilon_{n_{2}})} \right. \\ + \frac{|n_{1}\rangle\langle b|V_{g}|n_{2}\rangle\langle n_{1}n_{2}|I(\Delta_{db})|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{b} - \varepsilon_{n_{2}})} + \frac{|n_{1}\rangle\langle n_{1}b|I(\Delta_{db})|cn_{2}\rangle\langle n_{2}|V_{g}|d\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{d} - \varepsilon_{n_{2}})} \right] \\ + \sum_{n} \left[-\frac{|n\rangle\langle n|V_{g}|a\rangle\langle ab|I(\Delta_{db})|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n})^{2}} - \frac{|n\rangle\langle nb|I(\Delta_{db})|cd\rangle\langle a|V_{g}|a\rangle}{(\varepsilon_{a} - \varepsilon_{n})^{2}} - \frac{|a\rangle\langle a|V_{g}|n\rangle\langle nb|I(\Delta_{db})|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n})^{2}} \right. \\ + \frac{|n\rangle\langle n|V_{g}|a\rangle\langle ab|I'(\Delta_{db})|cd\rangle}{\varepsilon_{a} - \varepsilon_{n}} + \frac{|n\rangle\langle nb|I'(\Delta_{db})|cd\rangle\langle (d|V_{g}|d\rangle - \langle b|V_{g}|b\rangle)}{\varepsilon_{a} - \varepsilon_{n}} \\ + \frac{|a\rangle\langle ab|I'(\Delta_{db})|nd\rangle\langle n|V_{g}|c\rangle}{\varepsilon_{c} - \varepsilon_{n}} + \frac{|a\rangle\langle ab|I'(\Delta_{db})|cn\rangle\langle n|V_{g}|d\rangle}{\varepsilon_{d} - \varepsilon_{n}} \right] \\ + \frac{1}{2}|a\rangle\langle ab|I''(\Delta_{db})|cd\rangle\langle (d|V_{g}|d\rangle - \langle b|V_{g}|b\rangle) \right\}, \tag{15}$$

where a, b, c, and d are the one-electron states of the core or the valence electron. Here and in what follows, $\Delta_{ab} = \varepsilon_a - \varepsilon_b$, the prime on the summation symbol means that terms with vanishing denominator should be omitted from the summation, and each prime in $I'(\omega)$ and $I''(\omega)$ denotes the derivative over the energy argument. The summation over $\mu_{\rm core}$ runs over the angular-momentum projections of the core electron states, $\mu_{\rm core} = \pm 1/2$ for the $(1s)^2$ shell.

The second term in Eq. (12) is represented by

$$\Delta g_{\text{po}2} = 2 \sum_{\mu_c} \left[\langle \delta_{\text{Zee}} v | \Sigma(\varepsilon_v) | \delta_{\text{scr}} v \rangle + \langle \delta_{\text{Zee}} c | \Sigma(\varepsilon_c) | \delta_{\text{scr}} c \rangle \right], \tag{16}$$

where μ_c denotes the angular-momentum projection of the core electron state c, the perturbed wave functions are defined by

$$|\delta_{\text{Zee}}a\rangle = \sum_{n} \frac{|n\rangle\langle n|V_{g}|a\rangle}{\varepsilon_{a} - \varepsilon_{n}},$$

$$|\delta_{\text{scr}}a\rangle = \sum_{n} \frac{|n\rangle[\langle nb|I(0)|ab\rangle - \langle nb|I(\Delta_{ab})|ba\rangle]}{\varepsilon_{a} - \varepsilon_{n}}, \quad (17)$$

and (ab) = (vc) or (cv).

In the notations of Ref. [17], $\Delta g_{\rm pol}$ corresponds to the sum of the A, E, and G terms, and $\Delta g_{\rm po2}$ corresponds to the B term. Formulas (12)–(17) were derived in Ref. [17] by the two-time Green's function method [26]. They can be also

obtained by the standard Rayleigh-Schrödinger perturbation theory, as demonstrated in Appendix A.

B. Perturbed Zeeman-vertex contribution

The perturbed Zeeman-vertex contribution incorporates terms that can be expressed as nondiagonal matrix elements of the Zeeman vertex operator plus the corresponding reducible part. It is given by

$$\Delta g_{\text{vr,Zee}} = 2 \sum_{\mu_c} \{ \langle v | [\Lambda_{\text{Zee}}(\varepsilon_v) + V_{g,vv} \Sigma'(\varepsilon_v)] | \delta v \rangle + \langle c | [\Lambda_{\text{Zee}}(\varepsilon_c) + V_{g,cc} \Sigma'(\varepsilon_c)] | \delta c \rangle \},$$
 (18)

where $V_{g,aa} \equiv \langle a|V_g|a\rangle$, $\Sigma'(\varepsilon)$ denotes the derivative of the self-energy operator over the energy argument ε , and the perturbed wave function is defined as

$$|\delta a\rangle = \sum_{n} \frac{|n\rangle[\langle nb|I(0)|ab\rangle - \langle nb|I(\Delta_{ab})|ba\rangle]}{\varepsilon_{a} - \varepsilon_{n}} - \frac{1}{2}|a\rangle\langle ab|I'(\Delta_{ab})|ba\rangle, \tag{19}$$

with (ab) = (vc) or (cv). The matrix element of the Zeeman vertex operator (with the corresponding reducible part) is given by

$$\langle a|\Lambda_{\text{Zee}}(\varepsilon_a) + V_{g,aa}\Sigma'(\varepsilon_a)|\delta a\rangle = \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \sum_{n_1 n_2} \frac{\langle an_2|I(\omega)|n_1\delta a\rangle [\langle n_1|V_g|n_2\rangle - \langle n_1|n_2\rangle \langle a|V_g|a\rangle]}{(\varepsilon_a - \omega - u\varepsilon_{n_1})(\varepsilon_a - \omega - u\varepsilon_{n_2})}.$$
 (20)

In the notations of Ref. [17], $\Delta g_{vr,Zee}$ corresponds to the sum of the C1 + H1 terms and a part of the H3 term.

C. Perturbed screened-vertex contribution

The perturbed screened-vertex contribution is a part that can be expressed in terms of nondiagonal matrix elements of the screened (i.e., two-electron) vertex operator plus the corresponding reducible part. We represent it as a sum of the vertex and the reducible parts,

$$\Delta g_{\rm vr,scr} = \Delta g_{\rm ver,scr} + \Delta g_{\rm red,scr}. \tag{21}$$

The vertex part is

$$\Delta g_{\text{ver,scr}} = 2 \sum_{PQ} (-1)^{P+Q} \sum_{\mu_c} \left[\langle PvPc | \Lambda_{\text{scr}} | \delta QvQc \rangle + \langle PvPc | \Lambda_{\text{scr}} | QvQc \rangle + \frac{1}{2} \langle PvPc | \Lambda_{\text{scr.d}} | QvQc \rangle + \left(\langle Qc | V_g | Qc \rangle - \langle Pc | V_g | Pc \rangle \right) \right].$$
(22)

Here, P and Q are the permutation operators interchanging the valence and the core electrons, (PvPc) = (vc) or (cv), (QvQc) = (vc) or (cv), $(\delta QvQc) = (\delta vc)$ or (δcv) , $(Qv\delta Qc) = (v\delta c)$ or $(c\delta v)$, $(-1)^P$ and $(-1)^Q$ are the sign of the permutation P and Q, respectively, $|\delta a\rangle \equiv |\delta_{Zee}a\rangle$ is the first-order perturbation of the wave function by the magnetic potential as given in Eq. (17), and matrix elements of the two-electron vertex operator and its derivative are defined by

$$\langle ab|\Lambda_{\rm scr}|cd\rangle = \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \sum_{n_1 n_2} \frac{\langle an_2|I(\omega)|n_1c\rangle\langle n_1b|I(\Delta_{db})|n_2d\rangle}{(\varepsilon_a - \omega - u\varepsilon_{n_1})(\varepsilon_c - \omega - u\varepsilon_{n_2})},$$
(23)

 $\langle ab | \Lambda_{\rm scr.d} | cd \rangle$

$$=\frac{i}{2\pi}\int_{-\infty}^{\infty}d\omega\sum_{n_{1}n_{2}}\frac{\langle an_{2}|I(\omega)|n_{1}c\rangle\langle n_{1}b|I'(\Delta_{db})|n_{2}d\rangle}{(\varepsilon_{a}-\omega-u\varepsilon_{n_{1}})(\varepsilon_{c}-\omega-u\varepsilon_{n_{2}})}.$$
(24)

The reducible part is defined as

$$\Delta g_{\text{red,scr}} = 2[\langle v | \Sigma'(\varepsilon_v) | \widetilde{\delta v} \rangle + \langle c | \Sigma'(\varepsilon_c) | \widetilde{\delta c} \rangle], \tag{25}$$

where

$$|\widetilde{\delta a}\rangle = \sum_{\mu_{\text{core}}} \left\{ |\delta a\rangle [\langle ab|I(0)|ab\rangle - \langle ab|I(\Delta_{ab})|ba\rangle] + |a\rangle \left[\langle \delta ab|I(0)|ab\rangle + \langle a\delta b|I(0)|ab\rangle - \langle \delta ab|I(\Delta_{ab})|ba\rangle - \langle a\delta b|I(\Delta_{ab})|ba\rangle - \frac{1}{2} \langle ab|I'(\Delta_{ab})|ba\rangle (\langle a|V_g|a\rangle - \langle b|V_g|b\rangle) \right] \right\}. \quad (26)$$

Here, $|\delta a\rangle \equiv |\delta_{\text{Zee}}a\rangle$ and (ab) = (vc) or (cv).

In the notations of Ref. [17], $\Delta g_{\text{ver,scr}}$ corresponds to the sum of the C2 + H2 + F terms, and $\Delta g_{\text{red,scr}}$ corresponds to a part of the H3 term.

D. Double-vertex contribution

The double-vertex contribution is comprised of the matrix element of the double-vertex operator plus the corresponding reducible parts, all of them containing the third power of ω in the denominator. It is represented as

$$\Delta g_{\rm dvr} = \sum_{PO} (-1)^{P+Q} \sum_{\mu_c} \langle PvPc | \Lambda_{\rm dvr} | QvQc \rangle, \qquad (27)$$

where the operator Λ_{dvr} consists of four parts,

$$\Lambda_{\text{vr,dbl}} = 2\Lambda_{\text{dver}} + 2\Lambda_{\text{d.scr}} + \Lambda_{\text{d.Zee}} + \Lambda_{\text{dd.se}}.$$
 (28)

The first term in the sum is the double-vertex operator, which is defined by its matrix element as

$$2\langle ab|\Lambda_{\text{dver}}|cd\rangle = 2\frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \sum_{n_1 n_2 n_3} \frac{\langle an_3|I(\omega)|n_1 c\rangle \langle n_1 b|I(\Delta_{db})|n_2 d\rangle \langle n_2|V_g|n_3\rangle}{(\varepsilon_a - \omega - u\varepsilon_{n_1})(\varepsilon_c - \omega - u\varepsilon_{n_2})(\varepsilon_c - \omega - u\varepsilon_{n_3})}.$$
 (29)

The second term is the derivative of the screened-vertex operator, whose matrix element is

$$2\langle ab|\Lambda_{\rm d.scr}|cd\rangle = 2\langle c|V_g|c\rangle \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \frac{\partial}{\partial \varepsilon_c} \sum_{n_1 n_2} \frac{\langle an_2|I(\omega)|n_1c\rangle \langle n_1b|I(\Delta_{db})|n_2d\rangle}{(\varepsilon_a - \omega - u\varepsilon_{n_1})(\varepsilon_c - \omega - u\varepsilon_{n_2})}.$$
 (30)

The third term is the derivative of the Zeeman-vertex operator, which is

$$\langle ab|\Lambda_{\rm d.Zee}|cd\rangle = \langle ab|I(\Delta_{db})|cd\rangle \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \frac{\partial}{\partial \varepsilon_a} \sum_{n_1 n_2} \frac{\langle an_2|I(\omega)|n_1a\rangle \langle n_1|V_g|n_2\rangle}{(\varepsilon_a - \omega - u\varepsilon_{n_1})(\varepsilon_a - \omega - u\varepsilon_{n_2})}.$$
 (31)

The last term in Eq. (28) is the second derivative of the SE operator,

$$\langle ab|\Lambda_{\rm dd.se}|cd\rangle = \langle a|V_g|a\rangle\langle ab|I(\Delta_{db})|cd\rangle \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \frac{\partial^2}{\partial^2 \varepsilon_a} \sum_{n} \frac{\langle an|I(\omega)|na\rangle}{\varepsilon_a - \omega - u\varepsilon_n}.$$
 (32)

In the notations of Ref. [17], the four terms in the right-hand-side of Eq. (28) correspond to the D, I2, I1, and I3 terms, respectively.

IV. DIVERGENCIES

General formulas for the individual contributions presented in the previous section contain divergencies, both of the ultraviolet (UV) and infrared (IR) kind. The UV divergencies appear in contributions containing the first and the second power of ω in the denominator(s) inside the radiative photon loop. According to the standard procedure [27], UV divergencies are covariantly regularized by isolating one or two first terms of the expansion of the bound-electron propagators in terms of the interaction with the binding nuclear field. These terms are calculated in momentum space within the dimensional regularization, whereas the remainder is calculated in coordinate space by using the partial-wave expansion of the bound-electron propagators. The UV divergencies are identified in terms of one-loop renormalization constants and canceled when all individual contributions are added together. The cancellation of UV divergencies was demonstrated in Ref. [17] and does not need to be repeated here. In practical calculations, it is sufficient just to replace the free SE operator and the free one-loop vertex operator by their renormalized expressions.

We now turn to the IR divergencies, which have not been discussed in detail in Ref. [17]. These divergencies occur when the denominators of the electron propagators inside the radiative photon loop vanish at $\omega \to 0$. As we will show below, the IR divergencies originate from terms of the form

$$J_{\beta} \equiv \frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \frac{\langle ab|I(\omega)|ab\rangle}{(-\omega + i0)^{\beta}},\tag{33}$$

with $\beta \geqslant 2$. In the present investigation, we will encounter IR divergent terms with $\beta = 2$ and $\beta = 3$. It should be noted that the term with $\beta = 1$ (appearing, e.g., in the one-loop

SE matrix element) is IR safe. To show this, it is sufficient to rotate the left half of the ω integration contour on the right half-axis, $(-\infty,0) \to (\infty-i0,-i0)$, where the small addition -i0 indicates that this part lies on the lower bank of the cut of the photon propagator. On the upper bank of the cut of the photon propagator, $(\omega^2)^{1/2} = \omega$, whereas on the lower bank, $(\omega^2)^{1/2} = -\omega$. Therefore,

$$J_1 = \frac{i\alpha}{2\pi} \int_0^\infty d\omega \frac{\langle ab|\alpha_{1\mu}\alpha_2^{\mu}(e^{i\omega x_{12}} - e^{-i\omega x_{12}})|ab\rangle}{-\omega + i0}, \quad (34)$$

which is obviously converging at $\omega \to 0$.

To evaluate the IR divergent integrals J_2 and J_3 , we regularize the divergencies by introducing a finite photon mass μ in the photon propagator, evaluate the integral over ω analytically, and separate out the μ -dependent divergent terms, as described in Ref. [28]. The results for the IR divergent integrals (omitting terms vanishing in the limit $\mu \to 0$) are given by

$$J_2 = \frac{\alpha}{\pi} \left(\ln \frac{\mu}{2} + \gamma \right) + \frac{\alpha}{\pi} \langle ab | \alpha_{1\mu} \alpha_2^{\mu} \ln x_{12} | ab \rangle, \quad (35)$$

$$J_3 = \frac{\alpha}{4\mu} - \frac{\alpha}{4} \langle ab | \alpha_{1\mu} \alpha_2^{\mu} x_{12} | ab \rangle, \tag{36}$$

where γ is Euler's constant.

We now demonstrate the cancellation of the IR divergencies in the sum (11). It is convenient to express the IR-divergent parts of individual contributions in the form

$$\Delta g_{i,\text{IR}} = \sum_{PQ} (-1)^{P+Q} \sum_{\mu_c} \langle PvPc | \Lambda_{i,\text{IR}} | QvQc \rangle, \qquad (37)$$

where *i* runs over the contributions described in Sec. III. The perturbed-orbital SE contribution (12) does not contain any IR divergences. In the perturbed Zeeman-vertex contribution (18), IR divergencies intrinsically present in the vertex and reducible parts cancel each other, so that the total expression is finite and does not require a separate treatment. The other contributions in Sec. III contain IR divergencies, identified as follows:

$$\overline{\langle ab | \Lambda_{\text{ver,scr,IR}} | cd \rangle} = \frac{\alpha}{\pi} \left(\ln \frac{\mu}{2} + \gamma \right) 2 \left[\langle ab | I(\Delta_{db}) | c\delta_{\text{Zee}} d \rangle + \frac{1}{2} \langle ab | I'(\Delta_{db}) | cd \rangle \left(\langle d | V_g | d \rangle - \langle b | V_g | b \rangle \right) \right], \tag{38}$$

$$\langle ab|\Lambda_{\text{ver,red,IR}}|cd\rangle = \frac{\alpha}{\pi} \left(\ln \frac{\mu}{2} + \gamma \right) (-2) \left[\langle \delta_{\text{Zee}}ab|I(\Delta_{db})|cd\rangle + \langle a\delta_{\text{Zee}}b|I(\Delta_{db})|cd\rangle + \frac{1}{2} \langle ab|I'(\Delta_{db})|cd\rangle (\langle d|V_g|d\rangle - \langle b|V_g|b\rangle) \right], \tag{39}$$

 $\langle ab|\Lambda_{\text{dver,IR}}|cd\rangle = \frac{\alpha}{4\mu} 2\langle ab|I(\Delta)|cd\rangle\langle c|V_g|c\rangle + \frac{\alpha}{\pi} \left(\ln\frac{\mu}{2} + \gamma\right) 2\langle ab|I(\Delta)|\delta_{\text{Zee}}cd\rangle,\tag{40}$

$$\langle ab|\Lambda_{\rm d.scr,IR}|cd\rangle = \frac{\alpha}{4\mu}(-2)\langle ab|I(\Delta)|cd\rangle\langle c|V_g|c\rangle,\tag{41}$$

$$\langle ab|\Lambda_{\rm d.Zee,IR}|cd\rangle = \frac{\alpha}{4\mu}(-2)\langle ab|I(\Delta)|cd\rangle\langle a|V_g|a\rangle,\tag{42}$$

$$\langle ab|\Lambda_{\rm dd.se,IR}|cd\rangle = \frac{\alpha}{4\mu} 2\langle ab|I(\Delta)|cd\rangle\langle a|V_g|a\rangle. \tag{43}$$

It can be easily seen that the sum of all IR contributions (38)–(43) vanishes. In actual calculations, the IR-divergent contributions were isolated by introducing point-by-point subtractions in the integrand and then evaluated analytically according to Eqs. (35) and (36). Specifically, the matrix element of the double-vertex operator (29) is represented as [without the IR part accounted for by Eq. (40)]

$$2\langle ab|\Lambda_{\text{dver}}|cd\rangle = 2\frac{i}{2\pi} \int_{-\infty}^{\infty} d\omega \left\{ \sum_{n_{1}n_{2}n_{3}} \frac{\langle an_{3}|I(\omega)|n_{1}c\rangle\langle n_{1}b|I(\Delta_{db})|n_{2}d\rangle\langle n_{2}|V_{g}|n_{3}\rangle}{(\varepsilon_{a} - \omega - u\varepsilon_{n_{1}})(\varepsilon_{c} - \omega - u\varepsilon_{n_{2}})(\varepsilon_{c} - \omega - u\varepsilon_{n_{3}})} \right.$$

$$- \sum_{\mu_{a'}\mu_{c'}\mu_{c''}} \frac{\langle ac'|I(\omega)|a'c\rangle\langle a'b|I(\Delta_{db})|c''d\rangle\langle c''|V_{g}|c'\rangle}{(-\omega + i0)^{3}} - \sum_{\mu_{a'}\mu_{c'},n_{2}\neq c} \frac{\langle ac'|I(\omega)|a'c\rangle\langle a'b|I(\Delta_{db})|n_{2}d\rangle\langle n_{2}|V_{g}|c'\rangle}{(-\omega + i0)^{2}(\varepsilon_{c} - \varepsilon_{n_{2}})} \right\}$$

$$- \frac{\alpha}{2} \sum_{\mu_{a'}\mu_{c'},\mu_{c''}} \langle ac'|\alpha_{1\mu}\alpha_{2}^{\mu}x_{12}|a'c\rangle\langle a'b|I(\Delta_{db})|c''d\rangle\langle c''|V_{g}|c'\rangle}$$

$$+ \frac{2\alpha}{\pi} \sum_{\mu_{a'}\mu_{c'},n_{2}\neq c} \frac{\langle ac'|\alpha_{1\mu}\alpha_{2}^{\mu}\ln x_{12}|a'c\rangle\langle a'b|I(\Delta_{db})|n_{2}d\rangle\langle n_{2}|V_{g}|c'\rangle}{(\varepsilon_{c} - \varepsilon_{n_{2}})}, \tag{44}$$

where a' and c' (c'') denote the electron states that differ from a and c only by the angular-momentum projection, $\mu_{a'}$ and $\mu_{c'}$ ($\mu_{c''}$), correspondingly.

V. COMPUTATION OF INDIVIDUAL CONTRIBUTIONS

A. Perturbed-orbital self-energy contribution

The calculation of the perturbed-orbital SE contributions, given by Eqs. (13) and (16), is naturally reduced to a computation of nondiagonal matrix elements of the SE operator. In the present work, we use the numerical approach developed in Ref. [29], which has an important advantage of a rapid convergence of the partial-wave expansion. The perturbed wave functions in Eqs. (13) and (16) were calculated with help of the finite basis set for the Dirac equation constructed with *B* splines [30]. We do not use the dual kinetic balance (DKB) method [31] in the present work, since our calculations are performed with the point nuclear model, for which the DKB approach is not applicable.

The calculation of the perturbed-orbital SE contributions is simplified by the fact that the matrix element of the SE operator is diagonal in the relativistic angular-momentum quantum number κ and the angular-momentum projection μ of the external wave functions,

$$\langle a|\Sigma(\varepsilon)|b\rangle = \delta_{\kappa_a\kappa_b}\delta_{\mu_a\mu_b}(\ldots),\tag{45}$$

where (...) does not depend on the angular-momentum projections. Therefore, Eq. (13) involves the perturbed wave functions of just one angular symmetry. Equation (16) contains a summation over several angular symmetries of the perturbed wave functions (three in the general case but just two in our case). We also note that the perturbed wave functions $|\delta_{po}a\rangle$ and $|\delta_{scr}a\rangle$ contain imaginary parts which contribute when combined with the imaginary part of the SE operator.

For actual calculations of Eq. (16), it is convenient to move the summation over μ_c into the definition of one of the perturbed wave functions. For the first matrix element in Eq. (16), this can be done immediately. To do this in the second matrix element, we fix the angular-momentum projection of the c state in the magnetic perturbed wave function as $\mu_c = 1/2$,

$$|\delta_{\rm Zee}c\rangle \rightarrow \sum_{n} \frac{|n\rangle\langle n|V_g|c, \mu_c = 1/2\rangle}{\varepsilon_c - \varepsilon_n},$$
 (46)

and move the summation over μ_c into the definition of $|\delta_{\rm scr} c\rangle$, together with the appropriate factor s_{μ_c} that carries the dependence of the magnetic matrix element $\langle n|V_g|c\rangle$ on μ_c ,

$$|\delta_{\rm scr}c\rangle \to \sum_{\mu_c} s_{\mu_c} \sum_{n} \frac{|n\rangle [\langle nv|I(0)|cv\rangle - \langle nv|I(\Delta_{cv})|vc\rangle]}{\varepsilon_c - \varepsilon_n},$$
(47)

where

$$s_{\mu_c} = (-1)^{\mu_c - 1/2} C_{j_n \mu_c, j_c - \mu_c}^{10} \left[C_{j_n 1/2, j_c - 1/2}^{10} \right]^{-1}.$$
 (48)

In this way, we reduce by half the number of matrix elements of the SE operator to be computed.

To check our numerical procedure for computation of the perturbed wave functions in Eqs. (13) and (16), we replace the self-energy operator by the vacuum-polarization potential, $\Sigma(\varepsilon) \to V_{\rm VP}$, thus reproducing the corresponding vacuum-polarization screening corrections, calculated previously in Refs. [17,24].

B. Perturbed Zeeman-vertex contribution

The perturbed Zeeman-vertex contribution, defined by Eq. (18), can be considered as a nondiagonal generalization of the Zeeman-vertex correction for the hydrogen-like atom, specifically, Δg_{vr} given by Eq. (12) of Ref. [32]. The only difference of Eq. (18) as compared with the hydrogenic case is that the reference-state wave function on the right-hand side of the matrix element is replaced by the perturbed wave function $|\delta a\rangle$ given by Eq. (19). It should be mentioned that the perturbed wave function has contributions from several angular symmetries (three in the general case but only two in our case of $\kappa_v = \kappa_c = -1$) and an imaginary part, which contributes to the final result.

Similarly to the perturbed-orbital SE contribution, it is convenient to move the summation over the angular-momentum projection of the core electron μ_c in Eq. (18) into the definition of the perturbed wave function. For the first matrix element $\langle v| \dots |\delta v \rangle$, it can be done immediately. For the second matrix element $\langle c| \dots |\delta c \rangle$, some manipulations are

needed. Specifically, we observe that the dependence of the vertex matrix element on the angular-momentum projections of the external wave functions can be factorized out as

$$\langle c|\Lambda_{\text{Zee}}(\varepsilon_c)|c'\rangle = (-1)^{j_c - \mu_c} C^{10}_{j_{c'}\mu_{c'}, j_c - \mu_c}(\ldots), \qquad (49)$$

where (...) does not depend on the angular-momentum projections. Therefore, we can fix the momentum projection $\mu_c=1/2$ in the matrix element and redefine the perturbed wave function as

$$|\delta c\rangle \to \sum_{\mu_c} s_{\mu_c} |\delta c\rangle,$$
 (50)

where s_{μ_c} is given by Eq. (48).

The numerical evaluation of the perturbed Zeeman-vertex contribution is similar to the calculation of the diagonal matrix elements for the hydrogenic atoms, described in detail in Refs. [32,33]. Specifically, the whole contribution is separated into three parts,

$$\Delta g_{\text{vr,Zee}} = \Delta g_{\text{vr,Zee}}^{(0)} + \Delta g_{\text{vr,Zee}}^{(1)} + \Delta g_{\text{vr,Zee}}^{(2+)}, \tag{51}$$

where the superscript indicates the number of interactions with the binding Coulomb potential in the electron propagators. The first two terms on the right-hand side of the above equation are evaluated in momentum space, without any partial-wave expansion. Only the last term containing two and more interactions with the Coulomb field is calculated in coordinate space. Thanks to the separation of the one-potential term $\Delta g_{\rm vr,Zee}^{(1)}$, the partial-wave expansion of the remainder $\Delta g_{\rm vr,Zee}^{(2+)}$ converges rapidly and can be calculated to high accuracy. The contributions $\Delta g_{\rm vr,Zee}^{(0)}$ and $\Delta g_{\rm vr,Zee}^{(1)}$ need some generalization as compared with the diagonal case because of different angular symmetries of the perturbed wave function; the corresponding formulas were already derived in our calculation of the self-energy correction to the magnetic shielding [34,35].

We note that, as long as we calculate the vertex and the reducible part together and use an appropriate ω -integration contour (consisting of the low- and high-energy parts), the integrand in Eq. (20) has a smooth small- ω behavior. The would-be IR divergences in the vertex and reducible parts are canceled numerically at a given ω in this approach. Alternatively, the contribution with $\varepsilon_{n_1} = \varepsilon_{n_2} = \varepsilon_a$ can be separated out and evaluated analytically with help of formulas from Sec. IV. We checked the equivalence of both methods in order to test the consistency of our numerical procedure.

We mention here some of the further cross-checks of the numerical procedure made in order to eliminate possible errors: (i) by replacing $|\delta a\rangle \rightarrow |a\rangle$ in Eq. (20) we reproduced known results for the vertex and reducible diagonal matrix elements for the 1s and 2s hydrogenic states [32]; (ii) by replacing $\Lambda_{\rm Zee}(\varepsilon_a) + V_{g,aa} \Sigma'(\varepsilon_a) \rightarrow V_g$ in Eq. (20) we reproduced known results for the one-photon exchange correction to the g factor, both in coordinate and momentum space.

C. Perturbed screened-vertex contribution

The perturbed screened-vertex contribution, represented by Eqs. (21)–(26), is similar to the screened vertex and reducible corrections to the Lamb shift calculated in Refs. [36–38]. The general scheme of evaluation remains the same as for the

Lamb shift. Specifically, the vertex contribution is separated into the free (0) and many-potential (1+) parts,

$$\Delta g_{\text{ver,scr}} = \Delta g_{\text{ver,scr}}^{(0)} + \Delta g_{\text{ver,scr}}^{(1+)}.$$
 (52)

The free vertex part contains only free-electron propagators; it is renormalized and calculated in momentum space. The many-potential part contains one and more interactions with the binding Coulomb field; it is calculated in coordinate space by using the partial-wave expansion of the electron propagators. For the reducible contribution, we separate the zero-potential and one-potential contributions,

$$\Delta g_{\text{red,scr}} = \Delta g_{\text{red,scr}}^{(0)} + \Delta g_{\text{red,scr}}^{(1)} + \Delta g_{\text{red,scr}}^{(2+)}.$$
 (53)

The zero- and one-potential contributions are calculated in momentum space. The separation of the one-potential contribution improves the convergence of the partial-wave expansion in the many-potential reducible contribution.

The computation of the many-potential part is very similar to that for the Lamb-shift case. We introduce perturbed wave functions defined by Eqs. (17) and (26) and calculate them by using the finite-basis-set method [30]. Note that several different symmetries of the perturbed wave functions contribute to the final result (three in the general case but just two in our case).

Contrary to the many-potential part, the evaluation of the free part turned out to be different from our previous calculations for the Lamb shift [36,37]. The difference is that, for the Lamb shift, analytical formulas for the basic angular integrals were derived by using averaging over the angular-momentum projections of the valence state. In the *g*-factor calculations, the angular-momentum projection of the valence-electron state is fixed. Moreover, we need to account for the case when the angular symmetry of the perturbed wave function is different from the angular symmetry of the reference state. For this reason, we developed a generalized procedure for performing angular integrations in the momentum space. The evaluation of the free screened-vertex matrix elements is described in Appendix C.

Our numerical calculations of the many-potential vertex and reducible parts were performed by using the analytical representation of the Dirac-Coulomb Green's function in terms of the Whittaker functions. Integrations over the radial variables were carried out by the numerical approach described in detail in the recent review [28]. The partial-wave expansion was extended up to $|\kappa| = 30$; the remaining tail of the expansion was estimated by a polynomial fitting in $1/|\kappa|$.

We mention here several cross-checks of the computational procedure made in order to eliminate possible errors: (i) we checked that, in the diagonal case, our calculations reproduce known results for the Lamb shift [36]; (ii) we also checked that, by replacing the radiatively corrected vertex by the plain vertex, we reproduce known results for the one-photon exchange correction to the g factor, both in coordinate and momentum space. Specifically, as a part of this test, we checked that the replacement $\Gamma_{R,\mu} \to \gamma_{\mu}$ in Eq. (C1) yields the matrix element of the electron-electron interaction operator $I(\Delta)$ in the coordinate-momentum representation.

D. Double-vertex contribution

The computation of the double-vertex contribution is the most complicated part of the calculation. We start our discussion with the last three terms in the right-hand side of Eq. (28). These terms are induced by derivatives of the Zeeman-vertex, screened-vertex, and self-energy operators. Each of these operators were already examined, so we need only to evaluate the derivative. In actual calculations, we find it convenient to convert the derivative $\partial/(\partial \varepsilon_a)$ to $\partial/(\partial \omega)$ and to apply integration by parts, moving the derivative to the photon propagator. Specifically, we use the following identities:

$$\int_{-\infty}^{\infty} d\omega \frac{\partial}{\partial \varepsilon_{a}} \sum_{n_{1}n_{2} \neq a} \frac{\langle an_{2}|I(\omega)|n_{1}a\rangle \langle n_{1}|V_{g}|n_{2}\rangle}{(\varepsilon_{a} - \omega - u\varepsilon_{n_{1}})(\varepsilon_{a} - \omega - u\varepsilon_{n_{2}})}$$

$$= \int_{-\infty}^{\infty} d\omega \sum_{n_{1}n_{2} \neq a} \frac{\langle an_{2}|I'(\omega)|n_{1}a\rangle \langle n_{1}|V_{g}|n_{2}\rangle}{(\varepsilon_{a} - \omega - u\varepsilon_{n_{1}})(\varepsilon_{a} - \omega - u\varepsilon_{n_{2}})}, \quad (54)$$

and

$$\int_{-\infty}^{\infty} d\omega \frac{\partial^{2}}{\partial^{2} \varepsilon_{a}} \sum_{n \neq a} \frac{\langle an|I(\omega)|na \rangle}{\varepsilon_{a} - \omega - u\varepsilon_{n}}$$

$$= \int_{-\infty}^{\infty} d\omega \frac{\partial}{\partial \varepsilon_{a}} \sum_{n \neq a} \frac{\langle an|I'(\omega)|na \rangle}{\varepsilon_{a} - \omega - u\varepsilon_{n}}$$

$$= \int_{-\infty}^{\infty} d\omega \sum_{n \neq a} \frac{\langle an|I''(\omega)|na \rangle}{\varepsilon_{a} - \omega - u\varepsilon_{n}}.$$
(55)

The advantage of using the above formulas is that the derivative over the photon propagator can be easily evaluated analytically, contrary to the derivative over the electron propagator. An additional bonus from this transformation is that the behavior of the transformed integrand is smoother in the low- ω region.

All double-vertex contributions (29)–(32) contain the third power of ω in the denominator and thus are convergent in the ultraviolet region. Therefore, in principle, one does not need to separate out the zero-potential contributions in them. However, we find it advantageous to do so, since this subtraction improves the convergence of the partial-wave expansion drastically in the low-Z region.

Specifically, we separate out the contributions of the freeelectron propagators from the last three terms on the righthand side of Eq. (28) and evaluate them in momentum space, without any partial-wave expansion. Formulas for these zero-potential contributions are easily obtained by differentiation of the corresponding expressions for the zero-potential Zeeman-vertex, screened-vertex, and self-energy operators. A comparison of the numerical results obtained in the high-Z region with and without the subtraction was employed as a useful check of our numerical procedure. In the low-Z region, the convergence of the partial-wave expansion becomes increasingly slower. Even with the subtraction, we had to extend the partial-wave expansion up to $|\kappa_{\text{max}}| = 60$, in order to reach the desired numerical accuracy. The computation was carried out with help of the analytical representation of the Dirac-Coulomb Green's function [28].

The evaluation of the matrix elements of the double-vertex operator (29) is the most computationally intensive part. The

straightforward approach is to compute it as it stands, after separating IR divergencies according to Eq. (44). However, this turns out to be applicable only in the high-Z region; for lower Z, the convergence of the partial-wave expansion becomes excruciatingly slow. The standard way to accelerate the convergence would be to separate out the zero-potential double-vertex contribution and to calculate it in momentum space, which is a very cumbersome task. Fortunately, this is not really needed. It turns out that the convergence of the partial-wave expansion can be greatly accelerated if one separates out only a relatively simple part of the full zero-potential contribution; this is the approach used in the present work.

Specifically, we introduce the subtraction term $\Delta g_{\rm dver}^{(s)}$ which we obtain from $\Delta g_{\rm dver}$ by applying the following prescriptions: (i) all bound-electron propagators are replaced by the free-electron propagators, (ii) only the direct contribution is taken (PvPc = vc and QvQc = vc), (iii) only the Coulomb part of the electron-electron interaction is taken $[I(\Delta) \rightarrow \alpha/r_{12}]$. We note that, under these restrictions, the contribution in which the radiative loop is attached to the core-electron line vanishes after the summation over the angular-momentum projections of the core electrons, so that only the contribution with the radiative loop attached to the valence electron line survives.

The subtraction term defined in this way is represented in momentum space as (see Sec. III of Ref. [32])

$$\Delta g_{\text{dver}}^{(s)} = 4im \int \frac{d\mathbf{p}_1 d\mathbf{p}_2 d\mathbf{l}}{(2\pi)^6} V_{\text{core}}(\mathbf{l}) \overline{\psi}_v(\mathbf{p}_1) \times \left[\mathbf{\Lambda}_{\text{dver}}^{(0)}(\mathbf{p}_1, l, \mathbf{p}_2) \times \nabla_l \delta^3(\mathbf{q}) \right]_z \psi_v(\mathbf{p}_2), (56)$$

where $q = p_1 - l - p_2$, V_{core} is the Fourier-transformed potential of the charge density of the core electrons,

$$V_{\text{core}}(\mathbf{p}) = 2\frac{4\pi\alpha}{p^2} \int_0^\infty dz z^2 j_0(pz) [g_c^2(z) + f_c^2(z)], \quad (57)$$

and $\pmb{\Lambda}_{\text{dver}}^{(0)}$ is the free double-vertex operator defined as

$$\Lambda_{\text{dver}}^{(0)}(p_1, l, p_2) = -4\pi i\alpha \int \frac{d^4k}{(2\pi)^4} \gamma_\sigma \frac{\not p_1 - \not k + m}{(p_1 - k)^2 - m^2} \gamma_0
\times \frac{\not p_1 - \not k - \not l + m}{(p_1 - k - l)^2 - m^2} \gamma \frac{\not p_2 - \not k + m}{(p_2 - k)^2 - m^2} \gamma^\sigma.$$
(58)

Here, p_1 , l, and p_2 are four-vectors with a fixed time component, $p_1 = (\varepsilon_v, \mathbf{p}_1)$, $l = (\varepsilon_v, \mathbf{l})$, $p_2 = (\varepsilon_v, \mathbf{p}_2)$, $\mathbf{p} = p_\mu \gamma^\mu$, and $\gamma^\mu = (\gamma^0, \mathbf{p})$ are the Dirac matrices.

We now observe that the subtraction term (56) can be obtained from the one-potential vertex contribution given by Eq. (43) of Ref. [32], by replacing the nuclear Coulomb potential $V_C(q) = -4\pi Z\alpha/q^2$ with the potential of the core charge density $V_{\text{core}}(q)$. We, therefore, just use the formulas derived in Sec. III B of Ref. [32] in order to compute the double-vertex subtraction contribution (56) in momentum space.

The remainder represented by the difference $\Delta g_{\rm dver} - \Delta g_{\rm dver}^{(s)}$ was calculated in coordinate space by using the partial-wave expansion of the electron propagators. The low-energy part of the remainder was computed by using the finite basis-set method. The high-energy part of the remainder

was evaluated with the analytical representation of the Dirac Green's function. The radial integrations were computed by the numerical approach described in detail in the review [28].

The number of partial waves included into the computation varied from $|\kappa_{\text{max}}| = 50$ in the high- and medium-Z region to $|\kappa_{\text{max}}| = 75$ for $Z \le 10$. To cross-check our numerical procedure, we calculated the low-energy part of the remainder in two ways, using the analytical representation of the Green's function and the finite-basis-set B-spline representation.

VI. NONRELATIVISTIC QUANTUM ELECTRODYNAMICS EXPANSION

Nonrelativistic quantum electrodynamics (NRQED) [39] is the most general approach that allows a systematic derivation of the expansion of various atomic properties in terms of the fine-structure constant α . The expansion terms are represented as expectation values of some effective operators on the manyelectron nonrelativistic wave function of the reference state. The NRQED approach is most successful in describing light few-body systems since, for them, the Schrödinger equation can be solved to very high numerical accuracy by using the so-called explicitly correlated basis sets [40,41].

An important feature of the NRQED approach is that each term of the α expansion includes the electron-electron interaction (more exactly, the parameter 1/Z) to all orders. In the present work, we use this feature in order to access the contributions of order $1/Z^2$ and higher, which are not accounted for by the method presented in the previous sections, and in order to cross-check our computation of the 1/Z screening correction without expansion in $Z\alpha$.

The NRQED expansion of the radiative QED contribution to the bound-electron *g* factor of light atoms has the form

$$\delta g_{\text{QED}} = \alpha^3 g^{(3)} + \alpha^5 \ln \alpha g^{(5,\log)} + \alpha^5 g^{(5)} + \alpha^6 g^{(6)} + \cdots$$
(59)

The leading contribution of order α^3 comes from anomalous magnetic moment of the electron. The corresponding formulas were first derived by Hegstrom in the 1970s [42]. The result is

$$g^{(3)} = \frac{1}{\pi} \sum_{a} \left\langle Q_a^{(3)} \right\rangle_F,\tag{60}$$

where a numerates the electrons in the atom, the operator $Q_a^{(3)}$ is (in atomic units)

$$Q_a^{(3)} = \frac{1}{3} \left(-\frac{p_a^2}{2} + \frac{Z}{r_a} - \sum_{b \neq a} \frac{1}{r_{ab}} \right), \tag{61}$$

and $\langle . \rangle_F$ denotes the so-called Fermi (spin-factorized) radial matrix element, defined for an arbitrary one-electron operator H as

$$\langle \psi | \sum_{a} H_a \sigma_a | \psi \rangle = \sum_{a} \langle \phi | H_a | \phi \rangle_F 2S,$$
 (62)

where ψ is the full wave function of the reference state (i.e., the antisymmetrized product of the spatial and the spin functions), ϕ is the spatial part of the wave function, and $S = \sum_a \sigma_a$ is the spin operator. For more details we refer the reader to Ref. [20].

5	2.504 853 26 (15)
6	4.998 567 10 (10)
7	8.713 793 95 (8)
8	13.889 046 88 (8)
9	20.762 960 7 (2)
10	29.574 218 2 (2)
11	40.561 523 7 (2)
12	53.963 593 0 (8)
13	70.019 147 6 (2)
14	88.966 913 0 (2)

Numerical calculations of $g^{(3)}$ for Li and Li-like ions with $Z \le 14$ were carried out in Refs. [20–22]. The results can be represented in terms of the 1/Z expansion as

$$g^{(3)} = \frac{1}{\pi} \left(\frac{1}{24} Z^2 - \frac{274}{2187} Z + 0.07041 + 0.0017 \frac{1}{Z} + \cdots \right), \tag{63}$$

where the first two coefficients are known exactly [20] and the others are obtained by fitting the numerical data.

In the present work we calculate the next-order logarithmic contribution in Eq. (59), of order $\alpha^5 \ln \alpha$. The result is

$$g^{(5,\log)} = -\frac{64}{9} Z \ln Z \left\langle \sum_{a} \delta^{3}(\mathbf{r}_{a}) \right\rangle_{F}. \tag{64}$$

This formula is obtained as a straightforward generalization of the corresponding result for the hydrogenic ions derived in Ref. [43] by using the substitution of the hydrogenic electron density of the 2s state on the nucleus by the corresponding few-body density,

$$\langle \delta^3(\mathbf{r}) \rangle \equiv \frac{Z^3}{8\pi} \to \left\langle \sum_a \delta^3(\mathbf{r}_a) \right\rangle_F.$$
 (65)

The Fermi matrix elements of the δ function are calculated in the present work and listed in Table I. The results can be also represented in the form of the 1/Z expansion as

$$\left\langle \sum_{a} \delta^{3}(\mathbf{r}_{a}) \right\rangle_{F} = \frac{Z^{3}}{8\pi} \left(1 - 2.6557 \frac{1}{Z} + 0.914 \frac{1}{Z^{2}} + \cdots \right).$$
 (66)

A calculation of the nonlogarithmic contribution of order α^5 for few-electron atoms is a difficult problem since it involves a low-energy contribution, which is analogous to the Bethe logarithm for the Lamb shift. In the present work, we devise an approximation for the α^5 and α^6 contributions in Eq. (59), based on known results for the hydrogenic case. Specifically, we get

$$g^{(5)} + \alpha g^{(6)} \approx Z \left(\sum_{a} \delta^{3}(\mathbf{r}_{a}) \right)_{F} [a_{40} + (Z\alpha)a_{50}].$$
 (67)

^aGlazov et al., 2010 [17].

This formula is obtained from the hydrogenic result of Ref. [43] by the substitution (65), with a_{40} and a_{50} being the hydrogenic coefficients to orders $\alpha(Z\alpha)^4$ and $\alpha(Z\alpha)^5$ for the 2s state. The numerical results for the hydrogenic coefficients are $a_{40,se}(2s) = -10.707716$ [43], $a_{40,vp}(ns) = -16/15$ [44], $a_{50,se}(ns) = 23.282005$ [45], and $a_{50,vp}(ns) = 127\pi/216$ [44,46], with subscripts "se" and "vp" labeling contributions originating from the self-energy and vacuum polarization, correspondingly.

The hydrogenic coefficient $a_{40}(ns)$ is weakly n dependent (a 5% difference between the 1s and 2s states), so we expect the unknown screening contribution to it to be within 10%–20%. The next-order coefficient a_{50} is n independent, so the corresponding result for few-electron atoms is exact.

VII. RESULTS AND DISCUSSION

Numerical results of our all-order calculation of the self-energy screening correction to the g factor of the ground $(1s)^22s$ state of Li-like ions are presented in Table II. Our calculation is performed for the point nucleus. We note significant numerical cancellations between individual contributions, present throughout the whole Z region. For Z=82, our result is in perfect agreement with that of Ref. [17] but significantly more accurate.

To analyze our all-order numerical results for the self-energy screening correction, it is convenient to separate out its leading α and Z dependence, by introducing the function $G(Z\alpha)$ as follows:

$$\Delta g_{\text{sescr}} = \alpha^2 (Z\alpha) G(Z\alpha).$$
 (68)

The $Z\alpha$ expansion of the function G follows from the results obtained in Sec. VI,

$$G(Z\alpha) = g_{30} + (Z\alpha)^2 [g_{51} \ln(Z\alpha)^{-2} + g_{50} + (Z\alpha)g_{60} + \cdots],$$
(69)

where the leading coefficient $g_{30} = -274/(2187\pi) = -0.039\,880...$, $g_{51} = -2.6557/(8\pi) \times (32/9) = -0.3757$,

 $g_{50} \approx -2.6557/(8\pi) \times (-10.708)$, and $g_{60} = -2.6557/(8\pi) \times 23.282$. Figure 1 shows the comparison of the all-order numerical results for the scaled function $G(Z\alpha)$ with the predictions based on the $Z\alpha$ expansion (69). We conclude that our all-order results converge to the prediction of the $Z\alpha$ expansion as $Z \to 0$. We also observe that the inclusion of the approximate higher-order contributions g_{50} and g_{60} significantly improves the agreement between the all-order and $Z\alpha$ -expansion results. The deviation of the all-order results from the $Z\alpha$ expansion in the low-Z region is consistent with an additional contribution to g_{50} , $\delta g_{50} \approx 0.2$.

So far we addressed the self-energy screening correction of the relative order 1/Z as compared with the

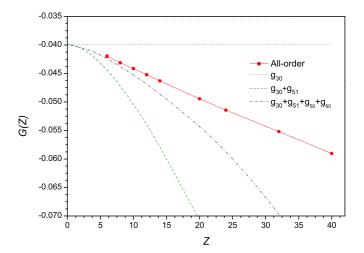

FIG. 1. The self-energy screening correction to the g factor of Lilike ions, in terms of the scaled function G(Z), defined by Eq. (68). The solid line and filled dots (red) represent the numerical all-order (in $Z\alpha$) results obtained in this work. The dotted line corresponds to the contribution of the leading $Z\alpha$ -expansion term g_{30} . The dashed line (green) corresponds to the contribution of two first terms of the $Z\alpha$ expansion, g_{30} and g_{51} . The dashed-dotted line (blue) shows the contribution of all known terms in Eq. (69).

leading, one-electron contribution. The complementary vacuum-polarization screening correction was calculated previously in Ref. [17] and recently reproduced in Ref. [24].

To complete the calculation of the QED screening effects, we need also to estimate the contribution of the higher-order screening $\propto 1/Z^{2+}$. For low-Z ions, this can be done immediately with help of the NRQED formulas presented in Sec. VI. Such an approach, however, would result in large uncertainties for high-Z ions. To avoid this, we devised an estimate which is equivalent to the one obtained from NRQED in the low-Z region but applicable also for high-Z ions. Specifically, we estimate the QED screening correction of order $1/Z^2$ as

$$g_{\rm QED}^{(1/Z^2)} \approx \alpha^3 \left[0.022412 + \frac{(Z\alpha)^2}{8\pi} \frac{c_2}{c_1} H^{(1)}(Z\alpha) \right],$$
 (70)

where the first term in the brackets comes from the 1/Z expansion of $\langle Q_a \rangle$ in Eq. (64), $c_1 = -2.6557$ and $c_2 = 0.914$ are the coefficients of the 1/Z expansion of $\langle \sum_a \delta(\mathbf{r}_a) \rangle_F$ in Eq. (66), and $H^{(1)}$ is the $1/Z^1$ higher-order remainder extracted from the all-order results obtained in this work. Specifically, we define $H^{(1)}$ by representing the all-order results for the self-energy and vacuum-polarization screening of relative order 1/Z as

$$g_{\text{QED}}^{(1/Z)} = \alpha^2 (Z\alpha) \left[-\frac{274}{2187\pi} + \frac{(Z\alpha)^2}{8\pi} H^{(1)}(Z\alpha) \right].$$
 (71)

We also devise an alternative estimation of the $1/Z^2$ QED screening contribution, based on the *one-electron* QED results. Specifically, we introduce the $1/Z^0$ higher-order remainder function $H^{(0)}$ by representing the all-order results for the one-electron self-energy and vacuum polarization of the 2s state as

$$g_{\text{QED}}^{(1/Z^0)} = \frac{\alpha}{\pi} + \alpha (Z\alpha)^2 \left[\frac{1}{24\pi} + \frac{(Z\alpha)^2}{8\pi} H^{(0)}(Z\alpha) \right]. \tag{72}$$

After that, our second approximation for the $1/Z^2$ QED screening correction is obtained as

$$g_{\rm QED}^{\left(1/Z^2\right)} \approx \alpha^3 \left[0.022412 + \frac{(Z\alpha)^2}{8\pi} \frac{c_2}{c_0} H^{(0)}(Z\alpha) \right],$$
 (73)

where $c_0 = 1$ is the first coefficient of the 1/Z expansion (66). The QED screening effects of order $1/Z^3$ and higher are relevant only for the lightest ions and can be accounted for in the leading order of the α expansion,

$$g_{\text{QED}}^{(1/Z^{3+})} = \frac{\alpha^3}{\pi} \left\langle \sum_a Q_a^{(3)} \right\rangle_F^{(3+)},$$
 (74)

where the matrix element contains all terms of its 1/Z expansion starting with $1/Z^3$,

$$\left\langle \sum_{a} Q_{a}^{(3)} \right\rangle_{F}^{(3+)}$$

$$= \left\langle \sum_{a} Q_{a}^{(3)} \right\rangle_{F} - \left(\frac{1}{24} Z^{2} - \frac{274}{2187} Z + 0.07041 \right). \tag{75}$$

Table III summarizes our results for the individual QED screening contributions for the ground state of Li-like ions. The column "SE(pnt)" lists results for the self-energy screening correction of the relative order 1/Z for the point nuclear model, taken from Table II.

The column "SE(fns)" presents our results for the shifts of the point-nucleus correction due to the finite nuclear size. It was calculated by taking the corresponding hydrogenic correction for the 2s state, obtained as in Ref. [47], and scaling it with help of Eq. (65). We assumed an uncertainty of 25% of this approximation. This correction is relevant only for high-Z ions; its error is negligible on the level of the total theoretical uncertainty.

The column "VP" lists results for the vacuum-polarization screening correction of the relative order 1/Z, as calculated in Ref. [24]. The uncertainty of this part comes from uncalculated higher-order contributions in the so-called magnetic-loop vacuum polarization. It was estimated by multiplying the results for the magnetic-loop correction in the free-loop approximation (see Ref. [24] for details) by the factor of $2(Z\alpha)^2$.

The column "h.o." presents results for the QED screening correction of the relative order $1/Z^{2+}$. They were obtained as a half-sum of the two approximations given by Eqs. (70) and (73) plus the higher-order screening contribution given by Eq. (74). The quoted uncertainty was obtained as twice the difference between the two approximations.

In Table III we compare our final theoretical values for the QED screening effect with previous results obtained by Glazov, Volotka, and co-authors [10,18]. We mention that our present approach is equivalent to theirs for the 1/Z part of the QED screening effects but differs in estimating the higherorder $1/Z^{2+}$ screening contributions. In our approach, we base our estimate on the NRQED results, whereas Refs. [10,18] approximately accounted for the higher-order screening by using various screening potentials. We observe the general consistency of the two calculations. This consistency is a rather strict test, because of delicate numerical cancellations between the individual terms required to get the final result. Still, the estimated error bars of the two calculations do not overlap in most cases, the deviation being on the level of 2σ - 3σ . This indicates that further work is needed in order to fully cross-check the QED screening calculations.

In Table IV we present a compilation of all known binding corrections to the g factor of the ground state of Li-like silicon, $^{28}\text{Si}^{11+}$. As compared with the analogous table in our previous investigation [20], the one-loop QED effects of the relative order 1/Z and $1/Z^{2+}$ and the nuclear recoil contributions were updated. The screened QED effects are calculated in the present work, whereas the nuclear recoil corrections of relative orders $1/Z^0$, $1/Z^1$, and $1/Z^{2+}$ were calculated by

deviations. It is interesting that the theoretical predictions, with time, are moving away from the experimental result, while steadily increasing in estimated accuracy.

Considering the comparison of the present theoretical prediction for silicon with the latest theoretical result of Glazov *et al.* [10], we note two small deviations. One is the difference of $+0.005\,(2)\times10^{-6}$ in the QED screening effect, whereas the other is the difference of $-0.003\,(3)\times10^{-6}$ in the $1/Z^{3+}$ electron-correlation effect. These two differences partially cancel each other, resulting in the total difference of the two total theoretical values of $+0.002\,(4)\times10^{-6}$, well within the quoted error bars.

Commenting on the disagreement with the experimental result for silicon, we note that not all effects in the theoretical prediction have been confirmed by independent calculations so far. Apart from the already mentioned small inconsistencies between the two calculations of the QED screening correction and the $1/Z^{3+}$ electron-correlation effect, the two-photon exchange QED effect has so far been calculated by one group only [18]. The other contributions in the theoretical prediction seem to be under better control. In particular, the nuclear recoil effect was recently rigorously calculated within QED by Shabaev and coworkers [19]. They found a mistake in the earlier calculation by Yan [21,22]. After correcting this mistake, the extrapolation of Yan's results (as in Ref. [20]) yields a result for silicon that agrees with that of Shabaev and coworkers up to a few parts in 10^{-10} . So, this effect should not be responsible for the deviation from the experimental value.

VIII. SUMMARY

We performed a calculation of the self-energy screening effects for the g factor of the ground state of Li-like ions. The contribution of the relative order 1/Z was calculated rigorously within QED, to all orders in the binding nuclear strength parameter $Z\alpha$. The higher-order screening contribution $\propto 1/Z^{2+}$ was calculated approximately, using results for the coefficients of the α expansion obtained in this work in the framework of nonrelativistic QED. In the result, we were able to improve the theoretical accuracy of the QED screening

effects in light Li-like ions and, as a consequence, the accuracy of the theoretical prediction of the *g* factor of Li-like silicon. The total theoretical result for Li-like silicon is in agreement with previous theoretical calculations but differs by about five standard deviations from the experimental result. We conclude that further theoretical and experimental work is needed in order to investigate the small deviations between different theoretical calculations and a much larger discrepancy with the experimental result.

APPENDIX A: PERTURBATION OF THE ONE-PHOTON EXCHANGE CORRECTION

In this section we consider the first-order perturbation of the one-photon exchange correction to the g factor of the ground state of a Li-like ion by some potential U. The result can be used to derive formulas for the perturbed-orbital self-energy and vacuum-polarization contributions.

The one-photon exchange correction to the g factor of a Li-like ion was derived in Ref. [14] (see also Ref. [49]) and

can be expressed in the following form:

$$\Delta g_{1ph} = 2 \sum_{\mu_c} [\Lambda_{1ph}(vcvc) + \Lambda_{1ph}(cvcv) - \Lambda_{1ph}(cvvc) - \Lambda_{1ph}(vccv)], \tag{A1}$$

where the summation runs over the angular-momentum projection of the core electron states μ_c and

$$\Lambda_{1\text{ph}}(abcd) = \sum_{n \neq a} \frac{\langle a|V_g|n\rangle\langle nb|I|cd\rangle}{\varepsilon_a - \varepsilon_n} + \frac{1}{4}\langle ab|I'|cd\rangle(\langle d|V_g|d\rangle - \langle b|V_g|b\rangle). \quad (A2)$$

Here, $I \equiv I(\Delta_{db})$ is the operator of the electron-electron interaction and the prime on I' denotes the derivative over the energy argument.

We now consider the first-order perturbation of $\Lambda_{1ph}(abcd)$ induced by some potential U. One perturbs the external wave functions, the electron propagator, and the energy argument of the electron-electron interaction operator $I(\Delta)$ with help of identities derived in Appendix B, specifically, Eqs. (B1), (B2), and (B5). The result is conveniently represented as a sum of two parts,

$$\delta_U \Lambda_{1ph}(abcd) = \Lambda_{irred}(abcd) + \Lambda_{red}(abcd).$$
 (A3)

The first part $\Lambda_{irred}(abcd)$ contains all terms that do not vanish within the Breit approximation (i.e., do not contain derivatives of the electron-electron interaction operator),

$$\Lambda_{\text{irred}}(abcd) = \sum_{n_{1}n_{2}} \left\{ \frac{\langle a|U|n_{1}\rangle\langle n_{1}|V_{g}|n_{2}\rangle\langle n_{2}b|I|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{a} - \varepsilon_{n_{2}})} + \frac{\langle a|V_{g}|n_{1}\rangle\langle b|U|n_{2}\rangle\langle n_{1}n_{2}|I|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{b} - \varepsilon_{n_{2}})} + \frac{\langle a|V_{g}|n_{1}\rangle\langle n_{1}b|I|n_{2}d\rangle\langle n_{2}|U|c\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{c} - \varepsilon_{n_{2}})} + \frac{\langle a|V_{g}|n_{1}\rangle\langle n_{1}b|I|n_{2}d\rangle\langle n_{2}|U|c\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{d} - \varepsilon_{n_{2}})} + \frac{\langle a|V_{g}|n_{1}\rangle\langle n_{1}|U|n_{2}\rangle\langle n_{2}b|I|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n_{1}})(\varepsilon_{a} - \varepsilon_{n_{2}})} \right\} - \sum_{n} \left\{ \frac{\langle a|V_{g}|n\rangle\langle n|U|a\rangle\langle ab|I|cd\rangle}{(\varepsilon_{a} - \varepsilon_{n})^{2}} + \frac{\langle a|V_{g}|n\rangle\langle nb|I|cd\rangle\langle a|U|a\rangle}{(\varepsilon_{a} - \varepsilon_{n})^{2}} + \frac{\langle a|U|n\rangle\langle nb|I|cd\rangle\langle a|V_{g}|a\rangle}{(\varepsilon_{a} - \varepsilon_{n})^{2}} \right\}. \tag{A4}$$

The second part $\Lambda_{red}(abcd)$ contains terms with derivatives of the electron-electron interaction,

$$\Lambda_{\text{red}}(abcd) = \sum_{n} \frac{\langle a|V_{g}|n\rangle\langle nb|I'|cd\rangle}{\varepsilon_{a} - \varepsilon_{n}} (\langle d|U|d\rangle - \langle b|U|b\rangle) + \sum_{n} \frac{\langle a|U|n\rangle\langle nb|I'|cd\rangle}{\varepsilon_{a} - \varepsilon_{n}} (\langle d|V_{g}|d\rangle - \langle b|V_{g}|b\rangle) \\
+ \sum_{n} \frac{\langle a|U|n\rangle\langle n|V_{g}|a\rangle}{\varepsilon_{a} - \varepsilon_{n}} \langle ab|I'|cd\rangle + \frac{1}{4} \langle ab|I''|cd\rangle (\langle d|V_{g}|d\rangle - \langle b|V_{g}|b\rangle) (\langle d|U|d\rangle - \langle b|U|b\rangle).$$
(A5)

Note that these formulas are symmetric with respect to $U \leftrightarrow V_g$. So, we could first perturb $\langle ab|I|cd \rangle$ with U and then with V_g , arriving at the same formulas.

The obtained expressions are equivalent to Eqs. (51)–(57) and (62)–(64) of Ref. [17] after the substitution $U \to U_{\rm VP}^{\rm el}$, and to Eqs. (19)–(29) of Ref. [17] after the substitution $U \to \Sigma$. Rewriting the above formulas in an equivalent way and assuming $U \to \Sigma$, we obtain the expression for the perturbed-orbital self-energy corrections, Eqs. (12)–(17).

APPENDIX B: PERTURBATIONS OF ENERGY, WAVE FUNCTION, AND PROPAGATOR

Let us consider the first-order perturbations of the energy, the wave function, and the electron propagator induced by a potential U. The energy and the wave function obtain the corrections of the standard form,

$$\delta_U \varepsilon_a = \langle a | U | a \rangle, \tag{B1}$$

$$\delta_U|a\rangle \equiv |\delta_U a\rangle = \sum_{k \neq a} \frac{|k\rangle\langle k|U|a\rangle}{\varepsilon_a - \varepsilon_k}.$$
 (B2)

We now evaluate the first-order perturbation of the electron propagator with the reference-state contribution omitted (i.e., the reduced Green's function). Perturbing the intermediate-state wave functions $|k\rangle$ and energies ε_a and ε_k , we obtain

$$\delta_{U}\left(\sum_{k\neq a} \frac{|k\rangle\langle k|}{\varepsilon_{a} - \varepsilon_{k}}\right) = \sum_{k\neq a \atop l\neq k} \frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{k} - \varepsilon_{l})(\varepsilon_{a} - \varepsilon_{k})} + \sum_{k\neq a \atop l\neq k} \frac{|l\rangle\langle l|U|k\rangle\langle k|}{(\varepsilon_{k} - \varepsilon_{l})(\varepsilon_{a} - \varepsilon_{k})} + \sum_{k\neq a} (\langle k|U|k\rangle - \langle a|U|a\rangle) \frac{|k\rangle\langle k|}{(\varepsilon_{a} - \varepsilon_{k})^{2}}.$$
 (B3)

Rearranging terms, we get

$$\sum_{\substack{k \neq a \\ l \neq k}} \frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{k} - \varepsilon_{l})(\varepsilon_{a} - \varepsilon_{k})} + \sum_{\substack{k \neq a \\ l \neq k}} \frac{|l\rangle\langle l|U|k\rangle\langle k|}{(\varepsilon_{k} - \varepsilon_{l})(\varepsilon_{a} - \varepsilon_{k})}$$

$$= \sum_{\substack{l,k \neq a \\ l \neq k}} \frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{k} - \varepsilon_{l})(\varepsilon_{a} - \varepsilon_{k})} + \sum_{\substack{l,k \neq a \\ l \neq k}} \frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{l} - \varepsilon_{k})(\varepsilon_{a} - \varepsilon_{l})} - \sum_{k \neq a} \frac{|k\rangle\langle k|U|a\rangle\langle a|}{(\varepsilon_{k} - \varepsilon_{a})^{2}} - \sum_{k \neq a} \frac{|a\rangle\langle a|U|k\rangle\langle k|}{(\varepsilon_{k} - \varepsilon_{a})^{2}}$$

$$= \sum_{\substack{l,k \neq a \\ l \neq k}} \frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{a} - \varepsilon_{k})(\varepsilon_{a} - \varepsilon_{l})} - \sum_{k \neq a} \frac{|k\rangle\langle k|U|a\rangle\langle a|}{(\varepsilon_{k} - \varepsilon_{a})^{2}} - \sum_{k \neq a} \frac{|a\rangle\langle a|U|k\rangle\langle k|}{(\varepsilon_{k} - \varepsilon_{a})^{2}}.$$
(B4)

Finally, we obtain

$$\delta_{U}\left(\sum_{k\neq a}\frac{|k\rangle\langle k|}{\varepsilon_{a}-\varepsilon_{k}}\right) = \sum_{l,k\neq a}\frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{a}-\varepsilon_{k})(\varepsilon_{a}-\varepsilon_{l})} - \sum_{k\neq a}\frac{|k\rangle\langle k|U|a\rangle\langle a|+|a\rangle\langle a|U|k\rangle\langle k|}{(\varepsilon_{k}-\varepsilon_{a})^{2}} - \langle a|U|a\rangle\sum_{k\neq a}\frac{|k\rangle\langle k|}{(\varepsilon_{a}-\varepsilon_{k})^{2}}.$$
 (B5)

For completeness, we present here also the first-order perturbation of the full propagator,

$$\delta_{U}\left(\sum_{k} \frac{|k\rangle\langle k|}{\varepsilon_{a} - \varepsilon_{k}}\right) = \sum_{l,k} \frac{|k\rangle\langle k|U|l\rangle\langle l|}{(\varepsilon_{a} - \varepsilon_{k})(\varepsilon_{a} - \varepsilon_{l})} - \langle a|U|a\rangle \sum_{k} \frac{|k\rangle\langle k|}{(\varepsilon_{a} - \varepsilon_{k})^{2}}.$$
 (B6)

APPENDIX C: FREE SCREENED VERTEX CONTRIBUTION

The matrix element of the zero-potential two-electron vertex operator can be written in the momentum space as [cf. Eqs. (59) and (60) of Ref. [36]],

$$\langle ab|\Lambda_{\rm scr}^{(0)}|cd\rangle = \alpha^2 \int \frac{d\mathbf{p}d\mathbf{p}'}{(2\pi)^6} \overline{\psi}_a(\mathbf{p}) A_{bd}^{\mu}(\Delta_{db}, \mathbf{q}) \times \Gamma_{R,\mu}(\mathbf{p}, \mathbf{p}') \psi_c(\mathbf{p}'), \tag{C1}$$

where $\overline{\psi} = \psi^{\dagger} \gamma^0$, $\mathbf{q} = \mathbf{p} - \mathbf{p}'$, $\Delta_{db} = \varepsilon_d - \varepsilon_b$, $\Gamma_{R,\mu}(\mathbf{p}, \mathbf{p}')$ is the renormalized free vertex operator (see Appendix A of Ref. [36]), and the four-vector potential A^{μ} in the Feynman gauge is given by

$$A_{bd}^{\mu}(\Delta, \boldsymbol{q}) = \frac{4\pi}{\boldsymbol{q}^2 - \Delta^2 - i0} \int d\boldsymbol{z} \psi_b^{\dagger}(\boldsymbol{z}) \alpha^{\mu} \psi_d(\boldsymbol{z}) e^{-i\boldsymbol{q}\cdot\boldsymbol{z}}. \quad (C2)$$

Performing the angular integration over \hat{z} for $A^{\mu} = (A^0, \mathbf{A})$, we obtain [see Eqs. (143) and (144) of Ref. [50]]

$$A_{bd}^{0}(\Delta, \mathbf{q}) = \frac{16\pi^{2}}{\mathbf{q}^{2} - \Delta^{2} - i0} \sum_{JM} i^{-J} s_{JM}^{db} Y_{JM}(\hat{\mathbf{q}}) P_{J}^{1,bd}(q),$$
(C3)

$$\mathbf{A}_{bd}(\Delta, \mathbf{q}) = \frac{16\pi^2}{\mathbf{q}^2 - \Delta^2 - i0} \sum_{JLM} i^{1-L} s_{JM}^{db} \mathbf{Y}_{JLM}(\hat{\mathbf{q}}) P_{JL}^{2,bd}(q),$$
(C4)

where $\hat{q} \equiv q/|q|$,

$$s_{LM}^{db} = \frac{(-1)^{j_b - \mu_b}}{\sqrt{4\pi}} C_{j_d \mu_d, j_b - \mu_b}^{LM}, \tag{C5}$$

 Y_{Lm} are the spherical harmonics, \mathbf{Y}_{JLM} are the vector spherical harmonics,

$$\mathbf{Y}_{JLM}(\hat{\mathbf{x}}) = \sum_{mq} C_{Lm,1q}^{JM} Y_{Lm}(\hat{\mathbf{x}}) \mathbf{e}_q,$$
 (C6)

and \mathbf{e}_q are the spherical components of the unity vector. The radial integrals are defined as

$$P_{J}^{1,bd}(q) = C_{J}(\kappa_{d}, \kappa_{b}) \int_{0}^{\infty} dx x^{2} j_{J}(qx) (g_{b}g_{d} + f_{b}f_{d}), \quad (C7)$$

$$P_{JL}^{2,bd}(q) = \int_{0}^{\infty} dx x^{2} j_{L}(qx) [g_{b}f_{d}S_{JL}(\kappa_{b}, -\kappa_{d})$$

$$- f_{b}g_{d}S_{JL}(-\kappa_{b}, \kappa_{d})], \quad (C8)$$

where $g_i = g_i(x)$ and $f_i = f_i(x)$ are components of radial wave functions, $j_l(z)$ is the spherical Bessel function, and the angular coefficients $C_J(\kappa_1, \kappa_2)$ and $S_{JL}(\kappa_1, \kappa_2)$ are given by Eqs. (274)– (277) of Ref. [50].

To perform angular integrations over \hat{p}_1 and \hat{p}_2 in Eq. (C1), we use the following representation for the vertex operator sandwiched between two Dirac wave functions [36]:

$$\overline{\psi}_{a}(\mathbf{p}_{1})\Gamma_{R,0}(\mathbf{p}_{1},\mathbf{p}_{2})\psi_{c}(\mathbf{p}_{2}) = \frac{\alpha}{4\pi}i^{l_{a}-l_{c}}\left[\mathcal{F}_{1}^{ac}\chi_{\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\chi_{\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2}) + \mathcal{F}_{2}^{ac}\chi_{-\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\chi_{-\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2})\right], \tag{C9}$$

$$\overline{\psi}_{a}(\mathbf{p}_{1})\Gamma_{R}(\mathbf{p}_{1},\mathbf{p}_{2})\psi_{c}(\mathbf{p}_{2}) = \frac{\alpha}{4\pi}i^{l_{a}-l_{c}}\left[\mathcal{R}_{1}^{ac}\chi_{\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\sigma\chi_{-\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2}) + \mathcal{R}_{2}^{ac}\chi_{-\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\sigma\chi_{\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2})\right.$$

$$+ \left(\mathcal{R}_{3}^{ac}\mathbf{p}_{1} + \mathcal{R}_{4}^{ac}\mathbf{p}_{2}\right)\chi_{\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\chi_{\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2}) + \left(\mathcal{R}_{5}^{ac}\mathbf{p}_{1} + \mathcal{R}_{6}^{ac}\mathbf{p}_{2}\right)\chi_{-\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\chi_{-\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2})\right], \tag{C10}$$

where $\chi_{\kappa\mu}(\hat{\boldsymbol{p}})$ are the spin-angular spinors. The one-loop vertex functions $\mathcal{F}_i^{ac} = \mathcal{F}_i^{ac}(p_1, p_2, \xi)$ and $\mathcal{R}_i^{ac} = \mathcal{R}_i^{ac}(p_1, p_2, \xi)$ are given in Appendix A of Ref. [36], with $q = |\mathbf{q}|$, $p_1 = |\mathbf{p}_1|$, $p_2 = |\mathbf{p}_2|$, and $\xi = \hat{\mathbf{p}}_1 \cdot \hat{\mathbf{p}}_2$. Now we perform integrations over all angular variables except for ξ in Eq. (C1) by using the following identity:

$$\int d\hat{\mathbf{p}}_1 d\hat{\mathbf{p}}_2 F(p_1, p_2, \xi) G(\hat{\mathbf{p}}_1, \hat{\mathbf{p}}_2) = \int_{-1}^1 d\xi F(p_1, p_2, \xi) g(\xi), \tag{C11}$$

where $F(p_1, p_2, \xi)$ and $G(\hat{p}_1, \hat{p}_2)$ are arbitrary functions of the specified arguments, and

$$g(\xi) = 2\pi \sum_{lm} P_l(\xi) \int d\hat{p}_1 d\hat{p}_2 Y_{lm}(\hat{p}_1) Y_{lm}^*(\hat{p}_2) G(\hat{p}_1, \hat{p}_2), \tag{C12}$$

where P_l are the Legendre polynomials. Using this identity, the matrix element of the free two-electron vertex can be expressed [36] (see also Sec. 3.2 of Ref. [50]) as

$$\langle ab | \Lambda_{\text{scr}}^{(0)} | cd \rangle = \frac{\alpha^{2}}{2\pi^{3}} \int_{0}^{\infty} dp_{1} dp_{2} \int_{-1}^{1} d\xi \frac{p_{1}^{2} p_{2}^{2}}{q^{2} - \Delta_{db}^{2} - i0} \sum_{J} \left\{ i^{J-l_{a}+l_{c}} P_{J}^{1}(q, bd) \left[\mathcal{F}_{1}^{ac} t_{l_{a}l_{c}}(J) + \mathcal{F}_{2}^{ac} t_{\bar{l}_{a}\bar{l}_{c}}(J) \right] \right.$$

$$\left. - \sum_{L} i^{L-l_{a}+l_{c}-1} P_{JL}^{2}(q, bd) \left[\mathcal{R}_{1}^{ac} s_{l_{a}\bar{l}_{c}}^{\sigma}(JL) + \mathcal{R}_{2}^{ac} s_{\bar{l}_{a}l_{c}}^{\sigma}(JL) \right] \right\}$$

$$\left. + \sum_{L} i^{2} \left[\mathcal{R}_{1}^{ac} (H) + \mathcal{R}_{2}^{ac} \mathcal{R}_{1}^{c}(H) \right] + \mathcal{R}_{2}^{ac} \left[\mathcal{R}_{1}^{c}(H) + \mathcal{R}_{2}^{ac} \mathcal{R}_{1}^{c}(H) \right] \right\}$$

$$+ p_1 \mathcal{R}_3^{ac} s_{l_a l_c}^{p_1}(JL) + p_2 \mathcal{R}_4^{ac} s_{l_a l_c}^{p_2}(JL) + p_1 \mathcal{R}_5^{ac} s_{\bar{l}_a \bar{l}_c}^{p_1}(JL) + p_2 \mathcal{R}_6^{ac} s_{\bar{l}_a \bar{l}_c}^{p_2}(JL) \bigg] \bigg\}, \tag{C13}$$

where $l_i = |\kappa_i + 1/2| - 1/2$, $\bar{l}_i = |\kappa_i - 1/2| - 1/2$. The angular factors $t_{l_1 l_2}$, $s_{l_1 l_2}^{\sigma}$, and $s_{l_1 l_2}^{p_i}$ are defined as follows:

$$t_{l_a l_c}(J) = \frac{1}{4\pi} \sum_{lm} P_l(\xi) \int d\hat{\boldsymbol{p}}_1 d\hat{\boldsymbol{p}}_2 Y_{lm}(\hat{\boldsymbol{p}}_1) Y_{lm}^*(\hat{\boldsymbol{p}}_2) \sum_{M} s_{JM}^{db} \chi_{\kappa_a \mu_a}^{\dagger}(\hat{\boldsymbol{p}}_2) Y_{JM}(\hat{\boldsymbol{q}}) \chi_{\kappa_c \mu_c}(\hat{\boldsymbol{p}}_1), \tag{C14}$$

$$s_{l_a l_c}^{\sigma}(JL) = \frac{1}{4\pi} \sum_{l_m} P_l(\xi) \int d\hat{\boldsymbol{p}}_1 d\hat{\boldsymbol{p}}_2 Y_{lm}(\hat{\boldsymbol{p}}_1) Y_{lm}^*(\hat{\boldsymbol{p}}_2) \sum_{M} s_{JM}^{db} \chi_{\kappa_a \mu_a}^{\dagger}(\hat{\boldsymbol{p}}_2) \boldsymbol{\sigma} \cdot \boldsymbol{Y}_{JLM}(\hat{\boldsymbol{q}}) \chi_{\kappa_c \mu_c}(\hat{\boldsymbol{p}}_1), \tag{C15}$$

$$s_{l_a l_c}^{p_i}(JL) = \frac{1}{4\pi} \sum_{lm} P_l(\xi) \int d\hat{\mathbf{p}}_1 d\hat{\mathbf{p}}_2 Y_{lm}(\hat{\mathbf{p}}_1) Y_{lm}^*(\hat{\mathbf{p}}_2) \sum_{M} s_{JM}^{db} \chi_{\kappa_a \mu_a}^{\dagger}(\hat{\mathbf{p}}_2) \hat{\mathbf{p}}_i \cdot Y_{JLM}(\hat{\mathbf{q}}) \chi_{\kappa_c \mu_c}(\hat{\mathbf{p}}_1). \tag{C16}$$

The angular coefficients (C14)–(C16) appeared previously in the calculation of the two-loop self-energy [see Eqs. (150) and (151) of Ref. [50], but there they were averaged over the angular-momentum projections of the reference states, which allowed us to simplify expressions considerably. In the present work we evaluate these angular coefficients in the general case. Using the standard Racah angular-momentum algebra, we obtain the following results:

$$\begin{split} t_{l_{a}l_{c}}(J) &= \frac{1}{4\pi} \sum_{ll_{1}} P_{l}(\xi) c_{l_{1}l_{2}}^{J} \sum_{m\sigma} s_{JM}^{db} C_{l_{1}m_{1},l_{2}m_{2}}^{JM} C_{l_{a}m_{a},1/2\sigma}^{j_{a}\mu_{a}} C_{l_{c}m_{c},1/2\sigma}^{j_{c}\mu_{c}} \\ &\times R_{3}(l_{a},m_{a},l,m,l_{1},m_{1}) R_{3}(l,m,l_{c},m_{c},l_{2},m_{2}), \\ &\qquad \qquad (C17) \\ s_{l_{a}l_{c}}^{\sigma}(JL) &= \frac{1}{4\pi} \sum_{ll_{1}} P_{l}(\xi) c_{l_{1}l_{2}}^{L} \sum_{m\sigma_{a}\sigma_{c}} s_{JM}^{db} C_{Lm_{L},1q}^{JM} C_{l_{a}m_{a},1/2\sigma_{a}}^{j_{a}\mu_{a}} C_{l_{c}m_{c},1/2\sigma_{c}}^{j_{c}\mu_{c}} \end{split}$$

$$\times \sqrt{2}(-1)^{1/2-\sigma_c}C_{1/2-\sigma_c,1/2\sigma_a}^{1q}C_{l_1m_1,l_2m_2}^{Lm_L}$$

 $\times R_2(l_1,m_1,l_2,m_1,m_1)R_2(l_1,m_1,l_2,m_2)$

 $\times R_3(l_a, m_a, l, m, l_1, m_1)R_3(l, m, l_c, m_c, l_2, m_2),$

$$s_{l_a l_c}^{p_1}(JL) = \frac{1}{\sqrt{12\pi}} \sum_{l l_1} P_l(\xi) c_{l_1 l_2}^L \sum_{m \sigma q} s_{JM}^{db} C_{Lm_L, 1q}^{JM} C_{l_a m_a, 1/2\sigma_a}^{j_a \mu_a}$$

$$\times C_{l_c m_c, 1/2\sigma_c}^{j_c \mu_c} C_{l_1 m_1, l_2 m_2}^{Lm_L} R_4(l_a, m_a, l, m, l_1, m_1, 1, q)$$

$$\times R_3(l, m, l_c, m_c, l_2, m_2),$$
(C19)

where

$$R_3(l_1, m_1, l_2, m_2, l_3, m_3)$$

$$= \int d\hat{\mathbf{x}} Y_{l_1 m_1}^*(\hat{\mathbf{x}}) Y_{l_2 m_2}(\hat{\mathbf{x}}) Y_{l_3 m_3}(\hat{\mathbf{x}}), \qquad (C20)$$

$$R_4(l_1, m_1, l_2, m_2, l_3, m_3, l_4, m_4)$$

$$= \int d\hat{\mathbf{x}} Y_{l_1 m_1}^*(\hat{\mathbf{x}}) Y_{l_2 m_2}(\hat{\mathbf{x}}) Y_{l_3 m_3}(\hat{\mathbf{x}}) Y_{l_4 m_4}(\hat{\mathbf{x}}), \qquad (C21)$$

and $c_{l_1 l_2}^L$ are coefficients of the expansion of the spherical harmonics of $\hat{z} \equiv \hat{z}_1 - \hat{z}_2$ into spherical harmonics of \hat{z}_1 and

 \hat{z}_2 [51]

$$Y_{LM}(\hat{\mathbf{z}}) = \sum_{\substack{l_1, l_2 = 0 \\ l_1 + l_2 = L}}^{L} c_{l_1 l_2}^{L} \sum_{m_1 m_2} C_{l_1 m_1, l_2 m_2}^{LM} Y_{l_1 m_1}(\hat{\mathbf{z}}_1) Y_{l_2 m_2}(\hat{\mathbf{z}}_2) , \quad (C22)$$

with

$$c_{l_1 l_2}^L = \sqrt{\frac{4\pi (2L+1)!}{(2l_1+1)!(2l_2+1)!}} \frac{z_1^{l_1} z_2^{l_2}}{z^L} (-1)^{l_2} . \tag{C23}$$

The integrals of three and four spherical harmonics R_3 and R_4 are evaluated in terms of Clebsch-Gordan coefficients by standard formulas [51].

For specific cases, the angular coefficients can be evaluated analytically, as done in Ref. [36]. In the present work we prefer to evaluate all sums of Clebsch-Gordan coefficients numerically. The specific cases of J=0 and J=1 were simplified and evaluated separately.

We now consider the matrix element of the zero-potential two-electron vertex operator for the Coulomb gauge of the exchanged photon. In this case the four-vector potential $A^{\mu} = (A^0, A^i)$ becomes

$$A_{bd}^{0}(\Delta, \boldsymbol{q}) = \frac{4\pi}{\boldsymbol{q}^{2} - i0} \int dz \psi_{b}^{\dagger}(z) \psi_{d}(z) e^{-i\boldsymbol{q}\cdot\boldsymbol{z}},$$

$$A_{bd}^{i}(\Delta, \boldsymbol{q}) = \left(\delta_{ij} - \frac{q_{i}q_{j}}{q^{2}}\right) \frac{4\pi}{\boldsymbol{q}^{2} - \Delta^{2} - i0}$$

$$\times \int dz \psi_{b}^{\dagger}(z) \alpha_{j} \psi_{d}(z) e^{-i\boldsymbol{q} \cdot \boldsymbol{z}}. \tag{C24}$$

To perform the angular integrations in the momentum integrations, we use the following representation:

$$\overline{\psi}_{a}(\mathbf{p}_{1})\frac{\mathbf{q}(\mathbf{q}\cdot\mathbf{\Gamma}_{R})}{q^{2}}\psi_{c}(\mathbf{p}_{2}) = \frac{\alpha}{4\pi}i^{l_{a}-l_{c}}[\widetilde{\mathcal{R}}_{3}^{ac}\mathbf{q}\chi_{\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\chi_{\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2}) + \widetilde{\mathcal{R}}_{5}^{ac}\mathbf{q}\chi_{-\kappa_{a}\mu_{a}}^{\dagger}(\hat{\mathbf{p}}_{1})\chi_{-\kappa_{c}\mu_{c}}(\hat{\mathbf{p}}_{2})],$$
(C25)

where the functions $\widetilde{\mathcal{R}}_i$ are expressed in terms of functions \mathcal{R}_i as follows:

$$\widetilde{\mathcal{R}}_{3}^{ac} = \frac{1}{q^{2}} \left[p_{2} \mathcal{R}_{1}^{ac} - p_{1} \mathcal{R}_{2}^{ac} + \mathcal{R}_{3}^{ac} \left(p_{1}^{2} - p_{12} \right) \right. \\
\left. + \mathcal{R}_{4}^{ac} \left(p_{12} - p_{2}^{2} \right) \right], \tag{C26}$$

$$\widetilde{\mathcal{R}}_{5}^{ac} = \frac{1}{q^{2}} \left[-p_{1} \mathcal{R}_{1}^{ac} + p_{2} \mathcal{R}_{2}^{ac} + \mathcal{R}_{5}^{ac} \left(p_{1}^{2} - p_{12} \right) \right. \\
\left. + \mathcal{R}_{6}^{ac} \left(p_{12} - p_{2}^{2} \right) \right], \tag{C27}$$
where $p_{12} = \mathbf{p}_{1} \cdot \mathbf{p}_{2}$.

We observe that the matrix element in the Coulomb gauge involves the same angular coefficients (C14)–(C16) as in the Feynman gauge.
