

Berezinskii-Kosterlitz-Thouless phase transition with Rabi-coupled bosonsKoichiro Furutani ^{1,2,*}, Andrea Perali ³ and Luca Salasnich ^{1,2,4}¹*Dipartimento di Fisica e Astronomia ‘Galileo Galilei’ and QTech Center, Università di Padova, Via Marzolo 8, 35131 Padova, Italy*²*Istituto Nazionale di Fisica Nucleare, Sezione di Padova, Via Marzolo 8, 35131 Padova, Italy*³*School of Pharmacy, Physics Unit, Università di Camerino, Via Madonna delle Carceri 9, 62032 Camerino, Italy*⁴*Istituto Nazionale di Ottica, Consiglio Nazionale delle Ricerche, Via Carrara 2, 50019 Sesto Fiorentino, Italy*

(Received 17 October 2022; revised 22 January 2023; accepted 4 April 2023; published 19 April 2023)

We theoretically investigate the superfluid–normal-state Berezinskii-Kosterlitz-Thouless transition in a binary mixture of bosonic atoms with Rabi coupling under balanced densities. We find the nonmonotonic behavior of the transition temperature with respect to the intercomponent coupling and amplification of the transition temperature for finite values of Rabi coupling, but for small intracomponent couplings. We develop the Nelson-Kosterlitz renormalization-group equations in the two-component Bose mixture and obtain the Nelson-Kosterlitz criterion modified by a fractional parameter, which is responsible for half-integer vortices, and by Rabi coupling. Adopting the renormalization-group approach, we clarify the dependence of the Berezinskii-Kosterlitz-Thouless transition temperature on the Rabi coupling and the intercomponent coupling. Analysis of the first and second sound velocities also reveals the suppression of quasicrossing of the two sound modes with a finite Rabi coupling in the low-temperature regime. Our results for a two-dimensional binary Bose superfluid contribute to the understanding of a broad range of multicomponent quantum systems such as two-dimensional multiband superconductors.

DOI: [10.1103/PhysRevA.107.L041302](https://doi.org/10.1103/PhysRevA.107.L041302)

The Berezinskii-Kosterlitz-Thouless (BKT) transition is one of the most striking phenomena that occur in a two-dimensional (2D) superfluid realized in thin films of ⁴He [1–16], ultracold atoms in a planar geometry [17–38] or in a spherical bubble trap [39–42], and exciton-polariton systems [43–50]. The BKT transition originates from unbindings of vortex-antivortex pairs and a proliferation of free vortices and antivortices [51–53]. It was first experimentally observed in thin ⁴He films [11] and later also in superconducting films [54–58], ultracold atomic gases [17–19,22,23,28–33,36], and exciton-polariton systems [48,49]. A BKT transition to electron-hole superfluidity in 2D atomic double layers has been also predicted and is under current investigation [59,60]. A stark contrast to three-dimensional (3D) superfluidity is a discontinuous jump of the superfluid density at the BKT transition temperature in a 2D superfluid [53,61–67]. It also leads to a jump of the second sound velocity, which was experimentally measured recently with a ³⁹K atomic gas [36]. To theoretically investigate the BKT transition, there are mainly two approaches. One is universal relations which are valid in the vicinity of the BKT transition temperature [22,23,68–70]. The other approach is to use the Nelson-Kosterlitz (NK) renormalization-group (RG) equations, which are responsible for RG flows of the vortex fugacity and the phase stiffness associated with the superfluid density [53]. An advantage of the RG approach is that it is also valid in the low-temperature regime.

In contrast to a single-component Bose gas, a multicomponent Bose mixture has significant qualitative differences

such as the Andreev-Bashkin entrainment effect between different species [38,71–77], the emergence of fractional circulation of vorticity [78–95], and the modification of the NK criterion [96,97]. There are also several theoretical analyses of the BKT transition in a bilayer XY model [98,99], which has similarities to 2D binary Bose mixtures, and a Monte Carlo simulation in a binary Bose mixture with finite Rabi coupling [100]. Finite Rabi coupling makes half-quantized vortices, which are vortices in one of the two components of the Bose atoms, topologically unstable but makes vortex molecules, which consist of two vortices of both components with positive or negative charges, stable. Reference [100] proposed that the topological excitations that induce the BKT transition are also replaced with vortex molecule-antimolecule pairs instead of vortex-antivortex pairs. Renormalization-group analysis taking into account these distinct topological excitations is crucial to predict physical quantities such as sound velocities and provide a coherent understanding of multicomponent superfluidity.

In this Letter, we consider a 2D atomic Bose gas confined in a quadratic region of area L^2 , at temperature T , and with a chemical potential μ across the BKT transition temperature through the RG approach. The bosonic gas is characterized by atoms with two hyperfine components in their energy-level spectrum. In addition to the usual intraspecies ($g = g_{11} = g_{22} > 0$) and interspecies (g_{12}) contact interactions, atoms in different hyperfine states interact via an external coherent Rabi coupling of frequency ω_R (≥ 0), which drives an exchange of atoms between the two components. The presence of the Rabi coupling implies that only the total number $N = N_1 + N_2$ of atoms is conserved, with $N_{a=1,2}$ being the number of atoms in the a th hyperfine component. The existence and

*koichiro.furutani@phd.unipd.it

stability of the ground state with balanced densities $N_1 = N_2$ were extensively discussed in Refs. [101,102]. We focus on the balanced and uniform ground state throughout this Letter.

Our two-component Bose-atom systems are a counterpart to strongly coupled multiband superconductors in which all the partial condensates are close to the Bose-Einstein-condensation regime. The Rabi coupling corresponds in multiband superconductors to the Cooper-pair exchange among different bands, and even in the case of multiband systems, it is the total number of carriers that is conserved, with redistribution of densities among the bands depending on the parameter configuration and on the renormalization of the chemical potential [103–105]. Hence, the present investigation of Rabi coupled bosons can shed light on the BKT transition and collective modes in 2D multiband superconductors, a growing field of study for their fundamental interest and quantum technology applications [106].

We first examine the two branches of elementary excitations, which are related to Rabi coupling and intercomponent coupling. To consider the BKT transition, we develop NK RG equations in the two-component Bose gas. We point out that the NK criterion that provides the BKT transition temperature is modified due to the fractional parameter. The fractional parameter is also responsible for the half circulation of vorticity in a population-balanced binary Bose mixture. With finite Rabi coupling, on the other hand, the NK criterion reduces to the one in the single-component case related to the formation of vortex molecule-antimolecule pairs. This modification of the NK criterion is also consistent with previous theoretical predictions based on Monte Carlo analysis under balanced densities [100]. We investigate the dependence of the BKT transition temperature on Rabi coupling and intercomponent coupling. It shows a nonmonotonic behavior with respect to the intercomponent coupling and amplifies the maximum transition temperature for each value of Rabi coupling. Finally, we determine the first and second sound velocities across the BKT transition temperature. We confirm the jump of the second sound velocity at the BKT transition temperature. At low temperatures, in particular, finite Rabi coupling is found to hinder quasicrossing behavior due to the presence of a gapped mode, in contrast to the single-component superfluids [65,107–111].

The Bogoliubov spectrum of elementary excitations in a uniform system has two branches, given by [101,102]

$$E_k^{(-)} = \sqrt{\varepsilon_k[\varepsilon_k + 2(\mu + \hbar\omega_R)]}, \quad (1)$$

$$E_k^{(+)} = \sqrt{\varepsilon_k(\varepsilon_k + 2A) + \bar{B}}, \quad (2)$$

with $\varepsilon_k = \hbar^2 k^2 / (2m)$ and m being the atomic mass. We set $\eta = g_{12}/g$, and the two parameters appearing in Eq. (2) are

$$A = \frac{1 - \eta}{1 + \eta}(\mu + \hbar\omega_R) + 2\hbar\omega_R, \quad (3)$$

$$B = 4\hbar\omega_R \left[\frac{1 - \eta}{1 + \eta}(\mu + \hbar\omega_R) + \hbar\omega_R \right]. \quad (4)$$

At the mean-field level, for the uniform ground state with balanced densities, the chemical potential μ reads [101,102]

$$\mu = \frac{1 + \eta}{2}gn - \hbar\omega_R, \quad (5)$$

where $n = N/L^2$ is the 2D total number density of bosons. The uniform ground state with balanced densities, characterized by $n_1 = n_2 = n/2$, is stable under the conditions $g + g_{12} > 0$ and $(g - g_{12})n + 2\hbar\omega_R > 0$ [101,102], namely, $-1 < \eta < 1 + 2\hbar\omega_R/(gn)$ with $g > 0$. By using Eq. (5), parameters A and B become $A = gn(1 - \eta)/2 + 2\hbar\omega_R$ and $B = 4\hbar\omega_R[gn(1 - \eta)/2 + \hbar\omega_R]$. For small wave numbers, the elementary excitations in Eqs. (1) and (2) read $E_k^{(-)} = c_B \hbar k$ and $E_k^{(+)} = \sqrt{\bar{B} + \varepsilon_k A} / \sqrt{B}$, showing explicitly that the mode $E_k^{(-)}$ is gapless, while the mode $E_k^{(+)}$ is gapped (if $\omega_R \neq 0$). Notice that $c_B = [gn(1 + \eta)/(2m)]^{1/2}$ is the Bogoliubov speed of sound for the uniform system. For $\eta = 1$, one recovers the familiar expression $c_B = \sqrt{gn/m}$.

By adopting Landau's approach [112], at finite temperature T , the superfluid density of the system is given by

$$n_s^{(0)}(T) = n - n_n^{(-)}(T) - n_n^{(+)}(T), \quad (6)$$

where

$$n_n^{(\pm)}(T) = -\frac{1}{2} \int \frac{d^2k}{(2\pi)^2} \frac{\hbar^2 k^2}{2m} f_T'(E_k^{(\pm)}) \quad (7)$$

is the thermally activated normal density due to the elementary excitations. In the formula, $f_T'(E)$ is the derivative with respect to E of the Bose distribution function $f_T(E) = 1/[e^{E/(k_B T)} - 1]$, with k_B being the Boltzmann constant.

It is important to stress that the superfluid density obtained in Eq. (6) does not take into account the formation of quantized vortices. The bare superfluid density $n_s^{(0)}(T)$ goes to zero at a critical temperature that is larger than T_c , the critical temperature of the BKT phase transition induced by the unbinding of vortex-antivortex pairs and the proliferation of free quantized vortices described by NK RG equations [51,52]. In a single-component 2D Bose gas, the NK RG equations are given by [53,113–115]

$$\partial_l K(l)^{-1} = 4\pi^3 y(l)^2, \quad \partial_l y(l) = [2 - \pi K(l)]y(l), \quad (8)$$

with $K(l) \equiv \hbar^2 n_s^{(l)}(T)/(mk_B T) = J(l)/(k_B T)$, $J(l) = \hbar^2 n_s^{(l)}(T)/m$ being the phase stiffness, and $y(l) \equiv \exp[-\mu_v(l)/(k_B T)]$, where $\mu_v(l)$ is the vortex chemical potential at the dimensionless scale l . The BKT critical temperature $T_c^{(0)}$ can be obtained by using the NK criterion, which provides a fixed point of Eqs. (8) [53]. According to this criterion, $T_c^{(0)}$ is given by the implicit formula

$$k_B T_c^{(0)} = \frac{\pi \hbar^2}{2m} n_s(T_c^{(0)}). \quad (9)$$

In a binary Bose mixture with balanced densities $\alpha_{a=1,2} = n_a/n = 1/2$; in contrast, we can obtain the following set of NK RG equations [100,113–115]:

$$\partial_l K(l)^{-1} = 4\pi^3 \Theta(\omega_R) y(l)^2, \quad (10a)$$

$$\partial_l y(l) = [2 - \pi \Theta(\omega_R) K(l)] y(l), \quad (10b)$$

where $\Theta(x)$ is the Heaviside step function with $\Theta(0) = 1/2$. It can be derived from the microscopic Lagrangian as in the single-component case. For the details of the derivation, see the Supplemental Material [115]. The RG equations (10)

give the modified NK criterion

$$k_B T_c = \frac{\pi \hbar^2}{2m} \Theta(\omega_R) n_s(T_c) \quad (11)$$

at the BKT critical temperature T_c . This NK criterion (11) is consistent with the Monte Carlo analysis in Ref. [100]. To calculate the RG flow, we use the initial conditions $K(0) = \hbar^2 n_s^{(0)}(T)/(mk_B T)$ and $\mu_\nu(0) = \pi^2 \Theta(\omega_R) J(0)/4$ [116–119], where $n_s^{(0)}(T)$ is calculated using Eq. (6) with Eqs. (1), (2), and (7). The maximum value of the RG scale is related to the system size as $l_{\max} = \ln(L/\xi)$, with $\xi = \hbar/\sqrt{2mg(n/2)}$ being the vortex core size. Here, we note that the higher-order derivative terms in the XY model can lead to corrections in the initial conditions for the RG flow. Indeed, it has been pointed out that the higher-order corrections are important for quantitatively accurate predictions of the BKT transition in XY models in particular for a small vortex chemical potential [120]. In our model of a binary Bose mixture, such a higher-order term of the superfluid velocity can arise and determine a quantitative change in our results with a small vortex chemical potential as well. In this Letter, however, since they are expected to produce moderate quantitative changes, we do not consider the effects of the spin-wave excitations on the vortex excitations, which will be the subject of a future investigation including the functional RG analysis [120,121].

The modification of the NK criterion in the absence of Rabi coupling reflects the half circulation of vorticity. Indeed, the circulation of vorticity is given by [100]

$$\kappa \equiv \oint ds \cdot \mathbf{v}_s = \frac{\hbar}{m} \oint ds \cdot \frac{|\psi_1|^2 \nabla \theta_1 + |\psi_2|^2 \nabla \theta_2}{|\psi_1|^2 + |\psi_2|^2}, \quad (12)$$

with $\psi_{a=1,2}$ being the a th complex bosonic field, where \mathbf{v}_s is the superfluid velocity associated with the superfluid phase $\theta_{a=1,2}$, and s is the vector along the closed path enclosing vortices. With fractional parameters $\alpha_a = n_a/n$, for instance, each of the circulations for vortices $(\psi_1, \psi_2) \sim (\sqrt{n_1} e^{\pm i\theta_0}, \sqrt{n_2})$, with $\theta_0 = \arctan(y/x)$, is given by $\kappa_1 = \pm 2\pi \alpha_1 \hbar/m$ [100]. For a population-balanced system $n_1 = n_2 = n/2$; in particular, $\alpha_{1,2} = 1/2$ gives rise to half vortices. In the presence of Rabi coupling, on the other hand, topological defects that lead to a BKT transition are replaced with vortex molecule-antimolecule pairs instead of vortex-antivortex pairs [78,81,100]. The formation of vortex molecule pairs modifies the RG equations as in Eqs. (10), which recover the ones for the single-component case in Eqs. (8).

Figure 1 shows the renormalized superfluid fraction computed with Eqs. (10) for $\tilde{g} = mg/\hbar^2 = 0.1$ and $\eta = 0$ with $L/\xi = 200$. Figure 1(a) displays the results with $\bar{\omega}_R = \hbar\omega_R/(n\hbar^2/m) = 0, 0.1, 1.0$. The horizontal axis is the dimensionless temperature $k_B T/(n\hbar^2/m) = 2\pi/(n\lambda_T^2)$, with $\lambda_T = [2\pi\hbar^2/(mk_B T)]^{1/2}$ being the thermal wavelength. The thin dotted curves stand for the bare superfluid fraction given by Eq. (6). Due to the finite size, the discontinuity of the renormalized superfluid fraction in the thermodynamic limit $L \rightarrow \infty$ is smeared and altered to a continuous drop [115]. In the single-component case plotted by the dashed curve, the superfluid fraction intersects with the thin dotted line for $k_B T = \pi\hbar^2 n_s/(2m)$ at the BKT transition temperature as in Eq. (9) in the thermodynamic limit. In contrast, in a population-

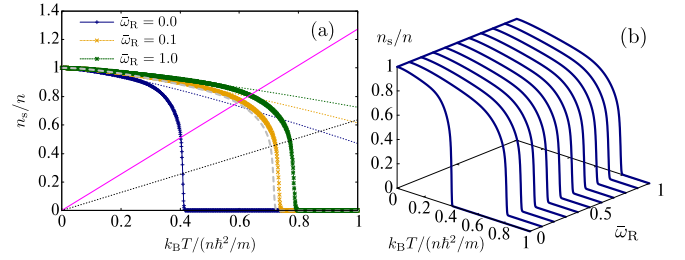

FIG. 1. Renormalized superfluid fraction calculated with Eqs. (10) for $\tilde{g} = mg/\hbar^2 = 0.1$ and $\eta = 0$. (a) displays the results with $L/\xi = 200$ and $\bar{\omega}_R = \hbar\omega_R/(n\hbar^2/m) = 0.0, 0.1, 1.0$. The horizontal axis is the dimensionless temperature $2\pi/(n\lambda_T^2) = k_B T/(n\hbar^2/m)$. The gray dashed curve stands for the superfluid fraction in a single-component Bose gas with $\tilde{g} = 0.1$ calculated with Eqs. (8). The thin dotted curves represent the bare superfluid fraction given by Eq. (6). The thin solid line and thin dotted line stand for $k_B T = \pi\hbar^2 n_s(T)/(4m)$ and $k_B T = \pi\hbar^2 n_s(T)/(2m)$, respectively. (b) shows the 3D plot of the renormalized superfluid fraction as a function of the temperature and Rabi coupling.

balanced binary Bose mixture, the superfluid fraction should intersect with the thin solid line for $k_B T = \pi\hbar^2 n_s/(4m)$ in the absence of Rabi coupling at the BKT transition temperature as in Eq. (11) in the thermodynamic limit. With finite Rabi coupling, on the other hand, the superfluid fraction intersects with the thin dotted line for $k_B T = \pi\hbar^2 n_s/(2m)$ at the BKT transition temperature in the thermodynamic limit as in the single-component Bose gas. A larger value of Rabi coupling shifts the transition temperature to a higher one. Figure 1(b) shows a 3D plot of the renormalized superfluid fraction as a function of the Rabi coupling and the temperature.

Figure 2 shows the phase diagram and the BKT transition temperature. In Fig. 2(a), the curves represent the η dependence of the BKT transition temperature in the thermodynamic limit with $\tilde{g} = 0.1$ and $\bar{\omega}_R = 0, 0.1, 0.5$. The shaded region below the transition temperature is the superfluid phase with a finite superfluid density for each of the values of Rabi coupling, while the system is in the normal phase above that temperature. We can observe that, as η increases from -1 , the transition temperature first increases. Near $\eta = 1 + 2\hbar\omega_R/(gn)$, it reaches a maximum for each $\bar{\omega}_R$ and changes to a gradual decrease. In particular, at $\bar{\omega}_R = 0$, as displayed in Fig. 2(a), the BKT transition temperature is symmetric with respect to η and reaches its maximum at $\eta = 0$. This is a natural consequence of the two symmetric excitation spectra $E_k^{(\pm)} = \sqrt{\varepsilon_k[\varepsilon_k + gn(1 \mp \eta)]}$ for $\omega_R = 0$. Figure 2(b) displays a 3D plot of the BKT transition temperature as a function of η and $\bar{\omega}_R$. It shows the monotonic increase of the transition temperature with increasing Rabi coupling $\bar{\omega}_R$. This behavior can be explained by the behavior of the energy gap in $E_k^{(+)}$ due to the Rabi coupling. As one increases the Rabi coupling, the gap size also increases, and the normal density $n_n^{(+)}$ in Eq. (7) decreases, while $n_n^{(-)}$ is unaffected. This results in an increase of the superfluid density in Eq. (6), thereby leading to an enhancement of the BKT transition temperature according to Eq. (11) by replacing the renormalized superfluid density with the bare one, which is a good approximation at low temperatures, as illustrated in Fig. 1(a). The maximum value of the transition temperature scaled by the one in the

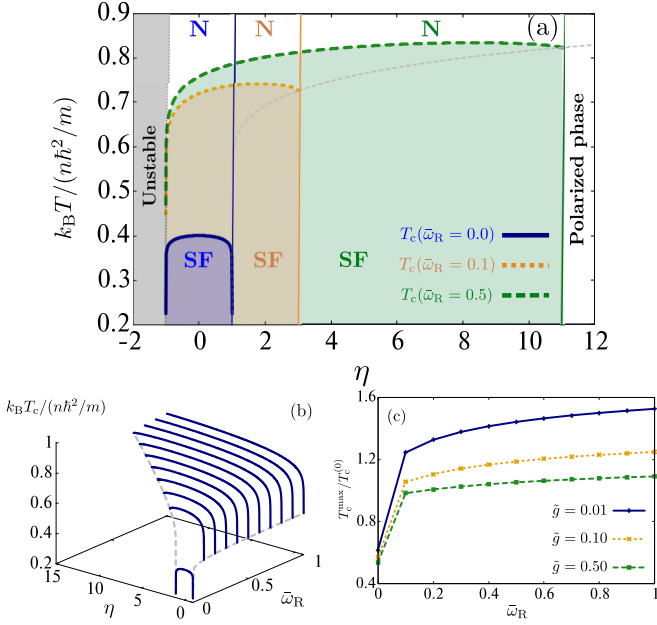

FIG. 2. Phase diagram of the binary Bose mixture and the BKT transition temperature to intercomponent coupling η and Rabi coupling $\bar{\omega}_R$. The curves in (a) represent the BKT transition temperature for $\tilde{g} = 0.1$ and $\bar{\omega}_R = 0.0, 0.1, 0.5$, below which the system is superfluid (SF). Above the transition temperature, it turns into a normal (N) phase with the vanishing superfluid fraction. The gray dotted curve in (a) represents the boundary at $\eta = 1 + 2\hbar\omega_R/(gn)$. The vertical thin lines represent $\eta = 1 + 2\hbar\omega_R/(gn)$ for each Rabi coupling above which the population-balanced ground state changes to the polarized phase. For $\eta < -1$, the population-balanced ground state is unstable. The two dashed curves in (b) represent the boundaries of the stable region of the ground state with balanced densities at $\eta = -1$ and $\eta = 1 + 2\hbar\omega_R/(gn)$, respectively. (c) shows the maximum value of the BKT transition temperature scaled by the transition temperature in the single-component case $T_c^{\max}/T_c^{(0)}$, with $\tilde{g} = 0.01, 0.1, 0.5$.

single-component case is shown in Fig. 2(c) with varying Rabi coupling. It monotonically increases by increasing $\bar{\omega}_R$. Figure 2(c) also reveals that the ratio $T_c^{\max}/T_c^{(0)}$ is prominently enhanced as one decreases the intracoupling strength \tilde{g} . This behavior comes from monotonically increasing the critical temperature $T_c^{(0)}$ in the single-component Bose gas faster than T_c^{\max} by increasing \tilde{g} .

The propagation of sound waves occurs in a fluid due to density fluctuations, and the sound velocity is determined by thermodynamic properties. In a superfluid, in addition to the density wave, there is another collective mode associated with the entropy fluctuations originating from the no-entropy flow in superfluids. The collective mode of the entropy wave is called the second sound [65,111,122–124]. The first and second sound velocities $c_{1,2}$ are the roots of Landau's two-fluid equation $c^4 - (v_s^2 + v_L^2)c^2 + v_T^2 v_L^2 = 0$, where v_T , v_s , and v_L are the isothermal, adiabatic, and Landau velocities, respectively, calculated from the free energy [65,115]. Figure 3 illustrates the first and second sound velocities for $\tilde{g} = 0.1$ and $\eta = 0, 0.5$ with $\bar{\omega}_R = 0.0, 1.0$. The upper branch is the first sound velocity c_1 , and the lower branch is identified as the second sound velocity c_2 , which survives as

FIG. 3. First and second sound velocities $c_{1,2}$ scaled by the Bogoliubov velocity c_B for $\tilde{g} = 0.1$ and $L/\xi = 200$. The intercoupling is set to be $\eta = 0$ in (a) and $\eta = 0.5$ in (b). The dashed curves correspond to $\bar{\omega}_R = 1.0$, while the solid curves correspond to $\bar{\omega}_R = 0.0$. The thin dotted curves represent $c_{1,2}$ in a single-component Bose gas for $\tilde{g} = 0.1$. The low-temperature behavior is magnified in (c) and (d). The insets in (c) and (d) illustrate the elementary excitations $E_k^{(\pm)}$. The solid curves stand for $E_k^{(-)}$, while the dotted and dashed curves represent $E_k^{(+)}$ for $\bar{\omega}_R = 0.0$ and $\bar{\omega}_R = 1.0$, respectively.

long as the superfluid fraction is finite. Finite Rabi coupling increases the critical temperature, as shown in Fig. 1, and allows the second sound to be present up to a higher temperature. At the low-temperature limit in the absence of Rabi coupling, using the linear dispersions $E_k^{(+)} \simeq c_+ \hbar k$, with $c_+ = [(1 - \eta)gn/(2m)]^{1/2}$, and $E_k^{(-)} \simeq c_B \hbar k$, one finds $v_T = v_s = c_B$ and $v_L = [(c_+^{-2} + c_B^{-2})/(c_+^{-4} + c_B^{-4})]^{1/2} = [(1 - \eta)/(1 + \eta^2)]^{1/2} c_B$ [115]. For $\eta = 0$ as shown in Fig. 3(a), in particular, the first and second sound velocities coincide with each other, $c_1 = c_2 = v_T = v_s = v_L = c_B$. The low-temperature behavior is shown in Fig. 3(c). With $0 < \eta < 1$ in the low-temperature regime without Rabi coupling, one observes $c_1 = v_s = v_T = c_B$ and $c_2 = v_L < c_B$, indicating that the sound modes are identified as the density mode and entropy mode, respectively, as illustrated by the dashed curves in Fig. 3(d). As one increases the temperature, the two branches exhibit a quasicrossing at which the density mode and entropy mode start to mix as in the case of the single-component 2D Bose gas plotted with the thin dotted curves in Fig. 3 or a 3D Bose gas [65,111]. In contrast, the solid curves in Fig. 3 imply that finite Rabi coupling suppresses the quasicrossing, as shown in Fig. 3(d), which is distinct from a single-component 2D Bose gas. This behavior can be understood by the presence of a gapped mode. With finite Rabi coupling, $E_k^{(+)}$ is gapped out, as shown in the insets in Figs. 3(c) and 3(d), and most thermally excited bosons occupy only the gapless mode $E_k^{(-)} \simeq c_B \hbar k$. Then, the major difference from the single-component case is only the additional prefactor $1/2$ in Eqs. (7) which affects the Landau velocity. Consequently, the Landau velocity is found to be identical to the Bogoliubov velocity, which also coincides with the adiabatic velocity at zero temperature [115]. It results in the suppression of quasicrossing at a low temperature. The temperature at which the quasicrossing occurs characterizes the temperature above which the second

sound can be detected by a density probe [64,110,125,126]. From an experimental point of view, the suppression of quasicrossing at finite temperature implies that the second sound mode is sensitive to a density probe even in the low-temperature regime, which can be tested with ultracold-atom experiments [76,125].

In summary, we investigated BKT transition in a Rabi-coupled binary Bose mixture under balanced densities. We have derived the NK RG equations for a binary Bose mixture and pointed out that the NK criterion is subject to change due to the fractional parameter and the Rabi coupling, consistent with the Monte Carlo simulation [100]. Based on the obtained RG equations, we clarified the whole behavior of the BKT transition temperature with respect to the Rabi coupling and intercomponent coupling. We found a nonmonotonic behavior of the transition temperature in terms of the intercomponent coupling and showed the maximum transition temperature for each value of Rabi coupling, finding regimes

of parameters resulting in an amplification of the transition temperature. Finally, we have studied the first and second sound velocities in this binary Bose mixture. We confirmed the jump in the second sound velocity as well as the superfluid density at the BKT transition temperature and elucidated the quasicrossing behavior of the two sound modes in the low-temperature regime. Our obtained NK criterion is consistent with the prediction based on Monte Carlo analysis for the population-balanced case [100]. On the other hand, Monte Carlo analysis has also predicted a double-step structure of the superfluid density in the population-imbalanced case [100,101,127–129]. A challenging open problem is to obtain a consistent result through the RG analysis in this population-imbalanced Bose mixture, extending the approach investigated in this work [121].
