

Rapid Communications

The Rapid Communications section is intended for the accelerated publication of important new results. Since manuscripts submitted to this section are given priority treatment both in the editorial office and in production, authors should explain in their submittal letter why the work justifies this special handling. A Rapid Communication should be no longer than 3½ printed pages and must be accompanied by an abstract. Page proofs are sent to authors.

Anomalous doublet splittings of binding energies in Dirac-Fock calculations

Chien-Tsun Chen and Keh-Ning Huang

Institute of Atomic and Molecular Sciences, Academia Sinica, P.O. Box 23-166, Taipei, Taiwan 10764, Republic of China and Department of Physics, National Taiwan University, Taipei, Taiwan 10764, Republic of China

(Received 18 September 1990)

Negative screening parameters for spin doublets have been reported for some atoms by using binding energies from Dirac-Fock calculations. The Dirac-Fock energies for spin doublets fail to converge to the same nonrelativistic limit because of unbalanced treatments of electron-electron correlations and give rise to spurious doublet splittings. We subtract from the Dirac-Fock doublet splittings the corresponding values in the nonrelativistic limit. The corrected doublet splittings form a smooth function of the atomic number and result in positive screening parameters. Detailed analyses are worked out for 3p spin doublets as an illustration.

To account for the screening of the nuclear charge on a given orbital electron by other electrons in a many electron atom, Sommerfeld¹ introduced the screening parameters σ_1 and σ_2 in the expanded form of the Dirac eigenenergy and obtained the following expression, in atomic units,

$$E(n, j) = -\frac{1}{2} \left[\frac{(Z - \sigma_1)^2}{n^2} + \frac{\alpha^2(Z - \sigma_2)^4}{n^4} \times \left(\frac{n}{j + 1/2} - \frac{3}{4} \right) + \dots \right]. \quad (1)$$

The first term is the total energy of a nonrelativistic electron, in which σ_1 accounts for the screening effect of other orbitals internal or external to the one under consideration. The second term is due to the combined effect of the mass variation, Darwin term, and spin-orbit interaction. The spin-orbit interaction which gives rise to the spin-doublet splitting is inversely proportional to r^3 ; for this reason σ_2 accounts dominantly for the screening effect of internal orbitals. Recently Misra, Sah, and Gokhale² reported negative screening parameters σ_2 of spin doublets in neutral atoms. The binding energies adopted in the calculation were Dirac-Fock (DF) energies evaluated with Dirac-Fock-Slater (DFS) wave functions;³ to this approach we refer to as DF(S). Before these authors, Burr and Carson⁴ have used the experimental energy values reported by Bearden and Burr⁵ in their calculations of σ_2 . However, the spin doublets of those atoms with negative σ_2 are unresolved in these experimental data. This negative screening anomaly shows the need to reexamine the formulation used in the study of spin doublets of binding energies.

The theoretical electron binding energy including relax-

ation is defined as

$$E_b = E_{\text{ion}} - E_{\text{ground}}, \quad (2)$$

where E_{ion} is the total energy of the ion with $N - 1$ electrons, and E_{ground} is the total energy of the atom in the ground state. Because the parameter σ_2 is completely determined by the doublet splitting rather than by its absolute position, we concentrate on the splittings of doublet levels. Consider specifically the splitting of 3p-electron binding energies in neutral atoms of Sc through Zn.

$$\Delta E = E_b[3p_{1/2}] - E_b[3p_{3/2}] = E_{\text{ion}}[3p_{1/2}] - E_{\text{ion}}[3p_{3/2}]. \quad (3)$$

For brevity, we use $[3p_j]$ to denote the configuration with one $3p_j$ electron absent from the ground configuration. Symbolically, we have

$$[3p_{1/2}] = (\text{core}) + 3p_{1/2}3p_{3/2}^4 3d_{3/2}^m 3d_{5/2}^n,$$

and a similar definition for $[3p_{3/2}]$

$$[3p_{3/2}] = (\text{core}) + 3p_{1/2}^2 3p_{3/2} 3d_{3/2}^m 3d_{5/2}^n.$$

In the DF formulation,^{6,7} the configuration-average energy for an atom or ion is expressed as

$$E_{\text{DF}} = \sum_a N_a I(a) + \sum_a \frac{N_a(N_a - 1)}{2} \left[F^0(aa) - \sum_{j \neq 0} C_j(a) F^j(aa) \right] + \sum_{a < b} N_a N_b \left[F^0(ab) - \sum_j D_j(ab) G^j(ab) \right], \quad (4)$$

where $I(a)$ is the one-particle integral including the kinetic energy and nuclear potential energy, N_a is the number of electrons in subshell a , $F^j(aa)$ and $G^j(ab)$ are the

direct and exchange integrals, respectively, and $C_j(a)$ and $D_j(ab)$ are certain coupling coefficients. Here the summation is over all subshells. In a complete analysis of atomic multiplet structures, one should determine all eigenstates of various total angular momenta and parities. This would involve calculations including nonaverage electrostatic and magnetic effects. Our concern, however, is the splittings of electron binding energies from configurations $[3p_{1/2}]$ and $[3p_{3/2}]$; it is therefore natural to take the configuration average of all the multiplets of each configuration.

The $3p$ doublet splitting in the DF formulation is given

$$\begin{aligned} \Delta E_{DF} \approx & -I(3p_{1/2}) + I(3p_{3/2}) - F^0(3p_{1/2}) + 3[F^0(3p_{3/2}) - \frac{1}{15}F^2(3p_{3/2})] - 2[F^0(3p_{1/2}3p_{3/2}) - \frac{1}{10}G^2(3p_{1/2}3p_{3/2})] \\ & - m[F^0(3p_{1/2}3p_{3/2}) - \frac{1}{6}G^1(3p_{1/2}3d_{3/2})] - n[F^0(3p_{1/2}3d_{5/2}) - \frac{1}{14}G^3(3p_{1/2}3d_{5/2})] \\ & + m[F^0(3p_{3/2}3d_{3/2}) - \frac{1}{60}G^1(3p_{3/2}3d_{3/2}) - \frac{9}{140}G^3(3p_{3/2}3d_{3/2})] \\ & + n[F^0(3p_{3/2}3d_{5/2}) - \frac{1}{10}G^1(3p_{3/2}3d_{5/2}) - \frac{1}{35}G^3(3p_{3/2}3d_{5/2})]. \end{aligned} \quad (6)$$

Furthermore, by taking $3p_{1/2} = 3p_{3/2} = 3p$, $3d_{3/2} = 3d_{5/2} = 3d$, we express the energy expression of the doublet splitting in the nonrelativistic limit approximately by

$$\Delta E_{DF-NR}^{\text{approx}} = \frac{1}{20}(3m - 2n)[G^1(3p3d) - \frac{3}{7}G^3(3p3d)]. \quad (7)$$

Unless $G^1(3p3d) - \frac{3}{7}G^3(3p3d)$ is negligibly small, the expression (7) vanishes only for empty $3d$ subshells $m=0$, $n=0$ and for completely filled $3d$ subshells $m=4$, $n=6$. The other case which satisfies the vanishing condition is for $m=2$ and $n=3$, the excited configuration of Mn. In Table I we also present values of $\Delta E_{DF-NR}^{\text{approx}}$ and compare them with the exact results ΔE_{DF-NR} and ΔE_{DF} . From the close agreement between $\Delta E_{DF-NR}^{\text{approx}}$ and ΔE_{DF-NR} , we conclude that the anomalous doublet splittings which remain in the nonrelativistic limit come from the nonvanishing energy expression of Eq. (7). When there are unfilled $3d$ subshells, these $3d$ electrons can interact with $3p$ electrons and result in various term structures. The nonrelativistic limits of the energy expressions for $[3p_{1/2}]$ and $[3p_{3/2}]$ are then different linear combinations of these terms; hence, the energy expressions correspond to different nonrelativistic limits. For this reason there arise unbalanced treatments of electron-electron correlations in

by

$$\Delta E_{DF} = E_{DF}[3p_{1/2}] - E_{DF}[3p_{3/2}]. \quad (5)$$

We present ΔE_{DF} and its nonrelativistic limit ΔE_{DF-NR} in Table I for neutral atoms of Sc through Zn. Physically the spin-doublet splitting is of relativistic origin and should vanish in the nonrelativistic limit. To explain why ΔE_{DF-NR} is nonvanishing in Table I, we consider its major contribution as follows. If we neglect the slight difference in orbital wave functions from the two configurations, we obtain the major contribution of the doublet splitting in the DF formulation as

configurations $[3p_{1/2}]$ and $[3p_{3/2}]$. The anomalous doublet splittings in the nonrelativistic limit should therefore be removed from the relativistic calculations, and the resulting doublet splittings are referred to as those of the corrected Dirac Fock (CDF). On the other hand, for either empty or completely filled $3d$ subshells, the configuration $[3p_{1/2}]$ or $[3p_{3/2}]$ has only one term. The energy expression of the $3p$ doublet splitting vanishes in the nonrelativistic limit, and no spurious contribution exists. In the multiconfiguration Dirac-Fock calculations of B- and F-like ions, Huang *et al.*⁸ encountered a similar situation in which the spin-orbit splittings were much larger than experimental data. The spurious nonrelativistic contributions were removed from theoretical spin-orbit splittings before comparisons were made with experiment.

Because the LS coupling is more suitable for most atoms with open outer shells, Lindgren and Rosén⁹ and Desclaux¹⁰ have taken an average over all relativistic configurations that correspond to a nonrelativistic configuration. These kind of approaches, together with the DFS formulation in which the exchange terms are replaced by a local potential, do not give rise to spurious contributions in the nonrelativistic limits. However, as far as the DF formulation is concerned, the present work pro-

vides an alternative method to give correct doublet splittings of binding energies.

Various theoretical results of the $3p$ doublet splittings for $Z = 18-38$ are compared with experiment in Table II. The doublet splittings of DF(S) and DF are similar and contain spurious contributions because they were both obtained from the same DF energy expressions. The CDF

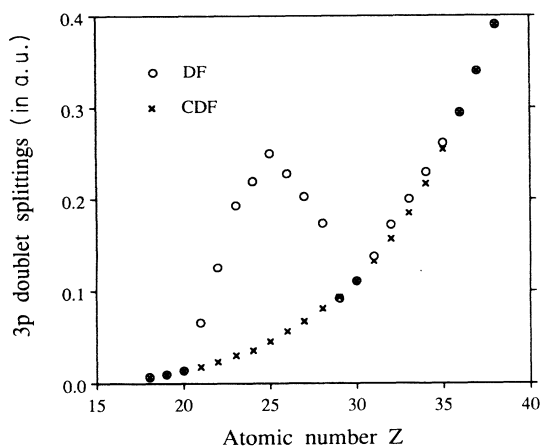

FIG. 1. Comparison of $3p$ doublet splittings of DF and CDF calculations for neutral Ar through Sr.

values are close to those of the DFS formulation, which does not suffer from this intrinsic deficiency. Nevertheless, the CDF values are, in principle, better than the DFS values because the exchange effect is treated exactly in the DF formulation. There is reasonable agreement between the CDF and experiment. The $3p$ doublet splittings of DF and CDF are plotted in Fig. 1. There is an apparent anomaly in the DF results for $Z=21-28$, whereas the CDF results form a smooth function of the atomic number Z . The screening parameters σ_2 derived from the DF and CDF values by means of Eq. (1) are presented in Table III. The CDF values also form a smooth function of the atomic number Z , in contrast to the DF values, which show negative screening parameters for $Z=22-25$.

We have elucidated the anomalous doublet splittings of

$3p$ -electron binding energies in the DF formulation for atoms with partially filled $3d$ subshells. A similar condition exists when there are partially filled $4p$ subshells. However as the overlap of the $4p$ wave function with the $3p$ wave function is small, the exchange integrals in Eq. (7) are expected to be small. This can be seen from Table II and Fig. 1, in which the CDF results deviate only slightly from the DF results for $Z=31-35$, for which the $4p$ subshells are partially filled. Spin doublet splittings for other subshells, such as $3d$, $4p$, $4d$, etc. can be analyzed similarly and are planned to be reported in a separate paper.
