(Received 28 January 2010; published 9 March 2010)

We explore an alternative way of finding the link between a \mathcal{PT} non-Hermitian Hamiltonian and a Hermitian one. Based on the analysis of the scattering problem for an imaginary potential and its time-reversal process, it is shown that any real-energy eigenstate of a \mathcal{PT} tight-binding lattice with on-site imaginary potentials shares the same wave function with a resonant transmission state of the corresponding Hermitian lattice embedded in a chain. It indicates that the \mathcal{PT} eigenstate of a \mathcal{PT} non-Hermitian Hamiltonian has a connection to the resonance transmission state of the extended Hermitian Hamiltonian.

I. INTRODUCTION

An imaginary potential usually appears in a system to describe physical processes phenomenologically due to its simplicity, which was investigated under the non-Hermitian quantum mechanics framework [1–10]. To discuss and explore the usefulness of the imaginary potential, one has to be able to establish a correspondence between a non-Hermitian system and a real physical system in an analytically exact manner. The effort to establish a parity-time (\mathcal{PT}) symmetric quantum theory as a complex extension of the conventional quantum mechanics [11–17] was stimulated by the discovery that a non-Hermitian Hamiltonian with simultaneous \mathcal{PT} symmetry has an entirely real quantum mechanical energy spectrum [18] and has profound theoretical and methodological implications.

When speaking of the physical significance of a non-Hermitian Hamiltonian, it is implicitly assumed that there exists another Hermitian Hamiltonian, which shares the complete or partial spectrum with it. Thus one of the ways of extracting the physical meaning of a pseudo-Hermitian Hamiltonian with a real spectrum is to seek for its Hermitian counterparts [8–10]. The metric-operator theory outlined in Ref. [11] provides a mapping of such a pseudo-Hermitian Hamiltonian to an equivalent Hermitian Hamiltonian. However, the obtained equivalent Hermitian Hamiltonian is usually quite complicated [11,19] and cannot be judged whether it describes real physics or is just an unrealistic mathematical object.

In this article, we try to find an alternative way to establish the connection between a pseudo-Hermitian Hamiltonian and a physics system. We consider a simple class of discrete systems, which are originally exploited to describe the solid-state systems in condensed matter physics. In such systems, the imaginary potential usually appears as source or sink, acting as the connection to the outer world. In this sense, the eigenstates of an unbroken \mathcal{PT} non-Hermitian Hamiltonian seem to be the dynamical equilibrium states of an open system. The strategy of this article is to seek the ways of analytical continuation of the eigenfunctions of a \mathcal{PT} non-Hermitian Hamiltonian into the stationary scattering states of an extended Hermitian system. It indicates that the \mathcal{PT} eigenstate of a \mathcal{PT} non-Hermitian Hamiltonian has a connection to the resonance transmission state of the extended Hermitian Hamiltonian.

This article is organized as follows, Sec. II is the scattering problem of the imaginary potential. In Sec. III, the connection between a resonant transmission state and a \mathcal{PT} -symmetry eigenstate is established. In Sec. IV, the illustrative examples are presented to demonstrate the main idea of this article. Section V is the summary and discussion.

II. SCATTERING PROBLEM OF THE IMAGINARY POTENTIAL

The first problem we address in our search for a physically meaningful \mathcal{PT} non-Hermitian Hamiltonian is how to associate the individual imaginary potential with the Hermitian subnetwork. Recently the formal theory of scattering for complex potentials in a one-dimensional continuous system was constructed (for review see Ref. [20] and references therein). To establish such a correspondence in a discrete system, we consider a simple model described by a non-Hermitian Hamiltonian H_γ . It is a tight-binding chain with uniform nearest-neighbor hopping integrals and an additional imaginary on-site potential on one site of a semi-infinite chain, which can be written as follows

$$\begin{aligned}
 H_\gamma &= H_{l\gamma} + H_g + H_{\text{sub}}, \\
 H_{l\gamma} &= -J \sum_{l=-\infty}^{-1} (a_l^\dagger a_{l+1} + \text{H.c.}) - i\gamma a_0^\dagger a_0, \\
 H_g &= -g(a_0^\dagger a_1 + a_1^\dagger a_0), \\
 H_{\text{sub}} &= \sum_{i,j=1}^{N_s} \kappa_{ij} (a_i^\dagger a_j + \text{H.c.}),
 \end{aligned} \tag{1}$$

where a_l^\dagger is the creation operator of the boson (or fermion) at the l th site, the tunneling strengths and imaginary potential are denoted by J , g , and $-i\gamma$ ($\gamma > 0$). We separate the Hamiltonian into several parts to characterize the configuration of the system. A sketch of such a system is given in Fig. 1(a). Here $H_{l\gamma}$ is a semi-infinite uniform chain with one potential $-i\gamma$ at the edge, H_g represents the coupling between this chain and an arbitrary subnetwork described by a Hermitian Hamiltonian H_{sub} . In this sense, the conclusion that will be obtained is applicable for a large class of systems.

To investigate the role of the imaginary potential in a discrete system, we will be concerned with the scattering problem of such a system: An incident plane wave e^{ikj} or

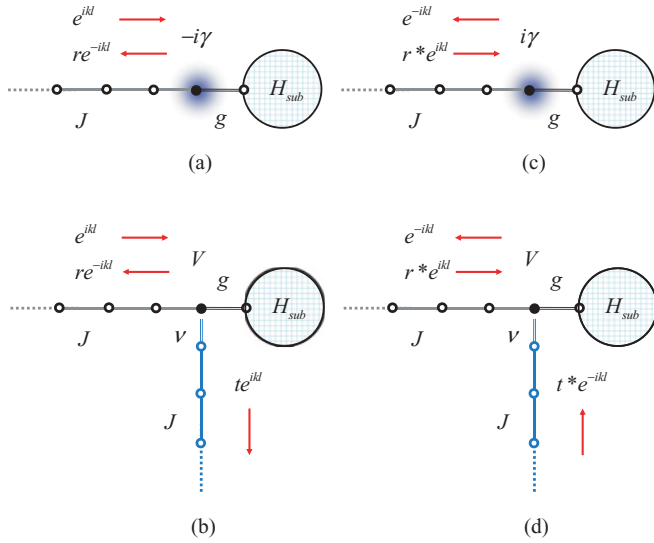

FIG. 1. (Color online) Schematic illustration of configurations of the typical tight-binding networks with imaginary potentials and their Hermitian counterparts. (a) The scattering process of an absorptive (absorbing) imaginary on-site potential, where H_{sub} is an arbitrary Hermitian subnetwork. (b) The corresponding Hermitian counterpart network of (a), which ensures the same wave function as (a) within the common region. The system consists of system (a) and an attaching lead. (c) and (d) describe the situations of (a) and (b) under the time-reversal operations. Note that (c) represents the scattering process of a new network different from (a), while (d) corresponds to the time-reversal scattering process of (c) in the same system.

a broad wave packet comes from the leftmost and is reflected and transmitted at the imaginary potential. The process can be represented by the wave function $f_1(j)a_j^\dagger|0\rangle$ ($j \in (-\infty, N_s]$) with

$$f_1(j \leq 0) = e^{ikj} + r_1 e^{-ikj}, \quad (2)$$

where r_1 represents the reflection amplitude. The explicit form of the wave function $f_1(j > 0)$ within the subnetwork depends on the the structure of H_{sub} . Generally speaking, the solution of r_1 cannot be obtained exactly even if the explicit form of H_{sub} is given. However, we will see that it does not affect the conclusion.

In the basis $\{a_j^\dagger|0\rangle | j \in (-\infty, N_s]\}$, the Schrödinger equations have the explicit form

$$\begin{aligned} -Jf_1(j-1) - Jf_1(j+1) &= Ef_1(j) \quad (j < 0), \\ -Jf_1(-1) - gf_1(1) &= (E + i\gamma)f_1(0), \\ -gf_1(0) + \sum_{i=1}^{N_s} \kappa_{i1} f_1(i) &= Ef_1(1) \\ \sum_{i=1}^{N_s} \kappa_{ij} f_1(i) &= Ef_1(j) \quad (j \in [2, N_s]), \end{aligned} \quad (3)$$

within all the regions. We will show that such a scattering process can occur in a Hermitian system.

It is well known that an imaginary potential, by means of an effective interaction, can serve as a reduced description for the outer world of an open system. Along this line, we consider a similar lattice system to H_γ , described by a Hermitian

Hamiltonian H_V . In this network, the imaginary potential is replaced by a real potential V and a semi-infinite chain is added, which acts as the complementary subspace or outer world if H_γ is regarded as an open system. The corresponding Hamiltonian has the form

$$\begin{aligned} H_V &= H_{lV} + H_g + H_{\text{sub}} + H_v + H_{lv} \\ H_{lV} &= -J \sum_{l=-\infty}^{-1} (a_l^\dagger a_{l+1} + \text{H.c.}) + Va_0^\dagger a_0 \\ H_v &= -v(a_0^\dagger b_1 + b_1^\dagger a_0) \\ H_{lv} &= -J \sum_{l=1}^{\infty} (b_l^\dagger b_{l+1} + \text{H.c.}), \end{aligned} \quad (4)$$

where b_l^\dagger is also the creation operator of the boson (or fermion) at the l th site. H_{lV} has a real potential V at the joint point of two semi-infinite uniform chains.

A sketch of such a system is given in Fig. 1(b). Note that the two systems assigned the same subnetwork $j \in (-\infty, N_s]$, which is referred to as the common region. The corresponding scattering wave functions within the two semi-infinite chains are $f_2(j)a_j^\dagger|0\rangle$ and $\tilde{f}(j)b_j^\dagger|0\rangle$ with

$$\begin{aligned} f_2(j \leq 0) &= e^{ikj} + r_2 e^{-ikj}, \\ \tilde{f}(j > 0) &= t e^{ikj}. \end{aligned} \quad (5)$$

In the basis $\{a_j^\dagger|0\rangle | j \in (-\infty, N_s], b_j^\dagger|0\rangle | j \in (1, +\infty)\}$, the Schrödinger equations are

$$\begin{aligned} -Jf_2(j-1) - Jf_2(j+1) &= Ef_2(j) \quad (j < 0), \\ -Jf_2(-1) - gf_2(1) - v\tilde{f}(1) &= (E - V)f_2(0), \\ -gf_2(0) + \sum_{i=1}^{N_s} \kappa_{i1} f_2(i) &= Ef_2(1), \\ \sum_{i=1}^{N_s} \kappa_{ij} f_2(i) &= Ef_2(j), \quad (j \in [2, N_s]), \end{aligned} \quad (6)$$

and

$$\begin{aligned} -v f_2(0) - J\tilde{f}(2) &= E\tilde{f}(1), \\ -J\tilde{f}(j-1) - J\tilde{f}(j+1) &= E\tilde{f}(j) \quad (j > 1). \end{aligned} \quad (7)$$

We can see that the Eqs. (3) and (6) within the common region have the same form except for the ones at the zeroth site with potentials. For the the same incident plane wave e^{ikj} , we have

$$E = -2J \cos k, \quad (8)$$

and furthermore, one can find that under the conditions

$$v^2 \sin k = \gamma J, \quad v^2 \cos k = VJ, \quad (9)$$

the solutions for r_1 and r_2 are identical. The above equivalent conditions can also be given in the energy-dependent form

$$v^2 = \frac{2\gamma J^2}{\Omega}, \quad V = -\frac{\gamma E}{\Omega}, \quad (10)$$

where $\Omega = \sqrt{4J^2 - E^2}$. Then the wave functions (2) and (5) within $j \in [-\infty, N_s]$ are the same. This indicates that for the incident plane wave e^{ikj} , the imaginary potential can be

regarded as a semi-infinite chain for wave escaping. It is worth pointing out that it is a conditional equivalence, which is only for the specific state. This equivalence is the building block for the investigation of this article.

Now we consider the relevant situations derived from the obtained results. We are interested in the case when the imaginary potential is source-like. Actually, applying the time-reversal operation on the previous scattering processes, [i.e., taking the complex conjugation for Eqs. (1) and (4)] the corresponding time-reversal solutions can be obtained, which are illustrated in Figs. 1(c) and 1(d). Figure 1(c) shows that the time-reversal solutions are for the new system $H_{\bar{\gamma}} = H_{\gamma}(\gamma \rightarrow -\gamma)$. Nevertheless, its counterpart H_V is invariant under time reversal. Figure 1(d) illustrates the corresponding time-reversal process of that in Fig. 1(b). Based on the processes in real physical systems illustrated in Figs. 1(b) and 1(c), the physics of the imaginary potential becomes clear: $-i\gamma$ acts as a drain lead, while $i\gamma$ acts as a source lead associated with an incoming plane wave. Although this is not a surprising result, we still verify it explicitly in a strict manner and will apply it to a \mathcal{PT} non-Hermitian system.

III. RESONANT TRANSMISSION CONDITION AND \mathcal{PT} SYMMETRY

The previous result is essentially about the stationary state for the infinite non-Hermitian system. Intuitively, a source and drain can produce a stationary state in a finite system between them when the gain rate is equal to the loss rate, or in an open system with injecting sources and absorbing sinks. The conceptual framework is required to substantiate this idea. In this section, we consider the stationary state of a non-Hermitian system based on the obtained scattering solutions of the imaginary potential.

Although we cannot get the explicit solution about the reflection amplitude r , the corresponding time-reversal process illustrated in Fig. 1(c) exhibits the facts: For an incident plane wave with amplitude 1, the reflected amplitude from the absorptive potential $-i\gamma$ is r , while for an incident plane wave with amplitude r^* , the reflected amplitude from the source potential $i\gamma$ is just 1. The fact $|r| = |r^*|$ indicates that if we combine the building blocks from Figs. 1(a) and 1(c) to construct a finite network with the geometry illustrated in Fig. 2(a), the stationary state may be formed in the following manner: a wave comes from the sources and sends back its time-reversed version. On the other hand, such a configuration has the \mathcal{PT} symmetry spontaneously, which was shown to process a real-energy eigenstate under certain conditions. In the aid of its Hermitian counterpart shown in Fig. 2(b), one can find that, in the case of the stationary state being formed, it just corresponds to the resonant transmission. Therefore the existence of the real-energy eigenstate of a \mathcal{PT} -symmetric system is connected to the occurrence of resonant transmission in a Hermitian system. It follows that we can find an alternative Hermitian counterpart to a \mathcal{PT} -symmetric Hamiltonian in the sense that they share the same eigenfunction within the common region. This should be the way more directly associated with the physics of the \mathcal{PT} -symmetric system. In the following sections, we will study the formation of the

FIG. 2. (Color online) Schematic illustration of configurations of a non-Hermitian tight-binding network with \mathcal{PT} symmetry and its Hermitian counterpart. They are constructed based on the building blocks represented in Fig. 1. It indicates that an eigenstate (stationary state) of (a) corresponds to a resonant transmission state of (b).

\mathcal{PT} symmetrical state by dealing with the more tractable models.

IV. ILLUSTRATIVE EXAMPLES

In this section, we investigate a simple exactly solvable system to illustrate the main idea of this article. To exemplify the previously mentioned analysis of relating the stationary states of a non-Hermitian \mathcal{PT} -symmetric Hamiltonian and a Hermitian one, we take H_{sub} to be the simplest network: a uniform chain. Then the sample Hamiltonian has the form

$$H_{\gamma\bar{\gamma}} = -J \sum_{l=1}^{N+2N_s-1} (a_l^\dagger a_{l+1} + \text{H.c.}) + i\gamma a_{N_s+1}^\dagger a_{N_s+1} - i\gamma a_{N+N_s}^\dagger a_{N+N_s}, \quad (11)$$

which is sketched in Fig. 3(a). It has \mathcal{PT} symmetry (i.e., $H_{\gamma\bar{\gamma}}^{\mathcal{PT}} = \mathcal{P}T H_{\gamma\bar{\gamma}} \mathcal{P}T = H_{\gamma\bar{\gamma}}$), which was studied systematically in the case of zero N_s [19]. Here \mathcal{P} and \mathcal{T} represent the space-reflection operator (or parity operator) and the time-reversal operator, respectively. The corresponding Hermitian Hamiltonian reads

$$H_{VV} = \left[-J \sum_{l=1}^{N+2N_s-1} a_l^\dagger a_{l+1} - J \sum_{l=\pm 1}^{\pm\infty} b_l^\dagger b_{l\pm 1} - v(a_{N_s+1}^\dagger b_{-1} + a_{N_s+N}^\dagger b_1) + \text{H.c.} \right] + V(a_{N_s+1}^\dagger a_{N_s+1} + a_{N_s+N}^\dagger a_{N_s+N}), \quad (12)$$

which is sketched in Fig. 3(b). It is a \mathcal{P} -symmetric system (i.e., $[\mathcal{P}, H] = 0$) which was studied in the framework of Bethe ansatz in the case of zero V [21]. The effects of \mathcal{P} and \mathcal{T} on the discrete system are

$$\mathcal{T}i\mathcal{T} = -i, \quad \mathcal{P}a_l^\dagger\mathcal{P} = a_{N+2N_s+1-l}^\dagger, \quad \mathcal{P}b_l^\dagger\mathcal{P} = b_{-l}^\dagger. \quad (13)$$

Note the region $\{a_l^\dagger|0\rangle, l \in [1, N+2N_s]\}$ is regarded as the common region of the two models. In the following, we present

FIG. 3. (Color online) Schematic illustrations of a tight-binding network with \mathcal{PT} symmetry and its Hermitian counterpart, where H_{sub} is a simple chain of length N_s . An exact Bethe-ansatz solution shows that the eigenstate of (a) accords to the equal-energy resonant scattering state of (b) under the condition (9).

the analytical results in the framework of Bethe ansatz for the two models to perform a comprehensive study.

A. \mathcal{PT} chain $H_{\gamma\bar{\gamma}}$

According to the \mathcal{PT} -symmetric quantum mechanics [16], system $H_{\gamma\bar{\gamma}}$ can be further classified to be either unbroken \mathcal{PT} symmetry or broken \mathcal{PT} symmetry, which depends on the symmetry of the eigenstates $|\psi_k^\gamma\rangle$ in different regions of γ . The time-independent Schrödinger equation is

$$H_{\gamma\bar{\gamma}}|\psi_k^\gamma\rangle = \varepsilon_k^\gamma |\psi_k^\gamma\rangle, \quad (14)$$

with corresponding eigenvalue ε_k^γ . The system is unbroken \mathcal{PT} symmetry if *all* the eigenfunctions have \mathcal{PT} symmetry

$$\mathcal{PT}|\psi_k^\gamma\rangle = |\psi_k^\gamma\rangle, \quad (15)$$

and all the corresponding eigenvalues are real simultaneously. This classification depends on the value of the parameter γ . Beyond the unbroken \mathcal{PT} -symmetric region the system is a broken \mathcal{PT} symmetry, where Eq. (15) does not hold for *all* the eigenfunctions and the eigenvalues of broken \mathcal{PT} -symmetric eigenfunctions are complex. We denote the single-particle eigenfunction in the form $|\psi_k^\gamma\rangle = \sum f_k^\gamma(l)a_l^\dagger|0\rangle$.

According to the Bethe-ansatz method, the eigenstates can be in the form of

$$f_k^\gamma = \begin{cases} C_L e^{ikj} + D_L e^{-ikj}, & j \in [1, N_s + 1] \\ A e^{ikj} + B e^{-ikj}, & j \in [N_s + 1, N_s + N] \\ C_R e^{ikj} + D_R e^{-ikj}, & j \in [N_s + N, N + 2N_s] \end{cases}. \quad (16)$$

The coefficients $\{A, B, C_{L(R)}, D_{L(R)}\}$ and the quasimomentum k are to be determined by the matching conditions

$$f_k^\gamma(j + 0^+) = f_k^\gamma(j + 0^-), \quad (17)$$

$$(j = N_s + 1, N_s + N),$$

and the corresponding Schrödinger equations of j ($j \neq N_s + 1, N + N_s$) in the center of the system

$$-Jf_k^\gamma(j + 1) - Jf_k^\gamma(j - 1) = \varepsilon_k^\gamma f_k^\gamma(j), \quad (18)$$

the Schrödinger equations of j for the sites $j = N_s + 1$ and $N_s + N$

$$\begin{aligned} & -Jf_k^\gamma(N_s + 2) - Jf_k^\gamma(N_s) \\ & = (\varepsilon_k^\gamma - i\gamma)f_k^\gamma(N_s + 1), -Jf_k^\gamma(N_s + N + 1) \\ & - Jf_k^\gamma(N_s + N - 1) \\ & = (\varepsilon_k^\gamma + i\gamma)f_k^\gamma(N_s + N), \end{aligned} \quad (19)$$

and for the edges of the system $j = 1$ and $N + 2N_s$

$$\begin{aligned} & -Jf_k^\gamma(2) = \varepsilon_k^\gamma f_k^\gamma(1) \\ & -Jf_k^\gamma(N + 2N_s - 1) = \varepsilon_k^\gamma f_k^\gamma(N + 2N_s). \end{aligned} \quad (20)$$

These lead to the equation of k

$$\begin{aligned} & -\gamma^2 \chi_k^2 [e^{ik(N-1)} - e^{-ik(N-1)}] \\ & = J^2 [e^{ik(N+2N_s+1)} - e^{-ik(N+2N_s+1)}], \end{aligned} \quad (21)$$

where

$$\chi_k = \frac{e^{ik(N_s+1)} - e^{-ik(N_s+1)}}{e^{ik} - e^{-ik}}. \quad (22)$$

The solutions of k can be classified in two categories: *physical* and *unphysical* states, which correspond to real and complex k , respectively. The corresponding energies are real or complex and in the form

$$\varepsilon_k^\gamma = -J(e^{ik} + e^{-ik}). \quad (23)$$

A straightforward algebra shows that there are at least $(N - 1)$ solutions of real k for arbitrary γ/J . In this article, we only focus on the physics counterparts of these states rather than the detailed form of the solutions.

B. Hermitian counterpart H_{VV}

For the Hamiltonian Eq. (12), it has \mathcal{P} and \mathcal{T} symmetry simultaneously (i.e., $\mathcal{P}H_{VV}\mathcal{P} = \mathcal{T}H_{VV}\mathcal{T} = H_{VV}$). Nevertheless, for a scattering state, a plane wave comes from the leftmost, the \mathcal{P} and \mathcal{T} symmetry are broken. We will show that under certain conditions, the wave function within the common region of $H_{\gamma\bar{\gamma}}$ and H_{VV} has \mathcal{PT} symmetry.

We can set the scattering wave function in the form of

$$f_k^V = \begin{cases} C_L^s e^{ikj} + D_L^s e^{-ikj}, & j \in [1, N_s + 1] \\ A^s e^{ikj} + B^s e^{-ikj}, & j \in [N_s + 1, N_s + N] \\ C_R^s e^{ikj} + D_R^s e^{-ikj}, & j \in [N_s + N, N + 2N_s] \end{cases}, \quad (24)$$

and

$$\tilde{f}_k^V = \begin{cases} e^{ikj} + r e^{-ikj} & j \in (-\infty, -1] \\ t e^{ikj}, & j \in [1, +\infty) \end{cases}, \quad (25)$$

where f_k^V represents the one within the common region, while \tilde{f}_k^V represents the one in the two leads. The reflection and transmission amplitudes r, t , coefficients $\{A^s, B^s, C_{L(R)}^s, D_{L(R)}^s\}$ and the quasimomentum k are to be determined by the matching conditions

$$\begin{aligned} & f_k^V(j + 0^+) = f_k^V(j + 0^-), \quad (j = N_s + 1, N + N_s) \\ & \tilde{f}_k^V(N_s + 1) = f_k^V(N_s + 1) \\ & \tilde{f}_k^V(N_s + N) = f_k^V(N_s + N), \end{aligned} \quad (26)$$

and the corresponding Schrödinger equations of j in the center of the system

$$\begin{aligned} -Jf_k^V(j+1) - Jf_k^V(j-1) &= \varepsilon_k^\gamma f_k^V(j) \\ -J\tilde{f}_k^V(j+1) - J\tilde{f}_k^V(j-1) &= \varepsilon_k^\gamma \tilde{f}_k^V(j), \end{aligned} \quad (27)$$

Schrödinger equations of j for the connection sites $N_s + 1$, $N_s + N$

$$\begin{aligned} -v\tilde{f}_k^V(-1) - Jf_k^V(N_s+2) - Jf_k^V(N_s) \\ = (\varepsilon_k^\gamma - V)f_k^V(N_s+1), -v\tilde{f}_k^V(1) - Jf_k^V(N_s+N+1) \\ - Jf_k^V(N_s+N-1) \\ = (\varepsilon_k^\gamma - V)f_k^V(N_s+N), \end{aligned} \quad (28)$$

and for the edges of the system $j = 1, N + 2N_s$

$$\begin{aligned} -Jf_k^V(2) &= \varepsilon_k^\gamma f_k^V(1) \\ -Jf_k^V(N+2N_s-1) &= \varepsilon_k^\gamma f_k^V(N+2N_s). \end{aligned} \quad (29)$$

The solution for reflection amplitude r is given, after a straightforward algebra, by

$$r = \frac{2iv^2\xi \sin(k) \sin^2[k(N-1)]}{J^2 \sin^2(k) - J^2\xi^2 \sin^2[k(N-1)]} - 1, \quad (30)$$

where

$$\xi = \frac{V}{J} + \frac{\sin[kN]}{\sin[k(N-1)]} - \frac{v^2}{J^2} e^{ik} - \frac{\sin[kN_s]}{\sin[k(N_s+1)]}. \quad (31)$$

We are interested in the resonant transmission state, which should be relevant to the \mathcal{PT} eigenstate of $H_{\gamma\bar{\gamma}}$, according to the previous time-reversal analysis. For $r = 0$ we have

$$\begin{aligned} 2iv^2\xi \sin(k) \sin^2[k(N-1)] \\ = J^2 \sin^2(k) - J^2\xi^2 \sin^2[k(N-1)]. \end{aligned} \quad (32)$$

The analysis in Sec. II indicates that, under the conditions (9), there should be a resonant transmission state corresponding to the eigenstate of Eq. (11). In fact, substituting Eq. (9) into Eq. (32), one can obtain

$$\begin{aligned} \gamma^2 \sin^2[k(N_s+1)] \sin[k(1-N)] \\ = J^2 \sin^2(k) \sin[k(N+2N_s+1)], \end{aligned} \quad (33)$$

which is just the reduced form of Eq. (21) for the *real* quasimomentum k . It can be shown exactly that there are at least $N-1$ real solutions for Eq. (33). This exhibits the connection between the two models (11) and (12) predicted by the previously mentioned analysis. Accordingly,

we have

$$\frac{C_{L(R)}}{C_{L(R)}^s} = \frac{D_{L(R)}}{D_{L(R)}^s} = \frac{A}{A^s} = \frac{B}{B^s}, \quad (34)$$

which shows that both functions within the common region are identical, that is, the scattering wave function $\{r, t, A^s, B^s, C_{L(R)}^s, D_{L(R)}^s\}$ is the analytical continuation of the one $\{A, B, C_{L(R)}, D_{L(R)}\}$.

Thus two eigenstates of the Hamiltonian (11) belong to the resonant transmission scattering states of *two different* systems (with different V and v). In this sense, nonorthogonality of the eigenstates of a pseudo-Hermitian Hamiltonian is obvious. In general the norm of a wave function is conserved in a Hermitian system, while the norm of many components of the wave function is not. These wave components may be associated with a truncated basis set, or a subspace of the full Hilbert space. The common region of $H_{\gamma\bar{\gamma}}$ and H_{VV} is a concrete example in the discrete system to demonstrate this fact.

V. CONCLUSION AND DISCUSSION

In conclusion, we present an alternative way of finding the link between a \mathcal{PT} non-Hermitian Hamiltonian and a Hermitian one, based on the analysis of the scattering problem for an imaginary potential. We find that the on-site absorptive imaginary potential can be equivalent to an attached semi-infinite chain as a drain with respect to a specific wave scattering problem. Applying this result and its extension to the time-reversal process on the \mathcal{PT} non-Hermitian system, the eigenstate problem is connected to that of the resonant transmission problem in the corresponding Hermitian system. It is shown that any real-energy eigenstate of a \mathcal{PT} tight-binding lattice with on-site imaginary potentials shares the same wave function with a resonant transmission state of the corresponding Hermitian lattice embedded in a chain.

It is not surprising that the \mathcal{PT} eigenstate has a connection to the resonance transmission state of the extended system. In general, for an infinite system with parity (\mathcal{P}) symmetry, it also has the time-reversal (\mathcal{T}) symmetry. An arbitrary scattering state, as an eigenstate of the system, probably breaks the \mathcal{P} , \mathcal{T} , and also \mathcal{PT} symmetries simultaneously. Interestingly, in the case of the resonance transmission, the corresponding wave function possesses \mathcal{PT} symmetry. Such wave functions can be the eigenstates of the \mathcal{PT} non-Hermitian system with the real eigenvalues.
