# Impulse approximation for three-dimensional inelastic atom-diatomic-molecule collisions 

Alexander Bogan, Jr.<br>Research Department, Grumman Aerospace Corporation, Bethpage, New York 11714<br>(Received 13 October 1973)

#### Abstract

The impulse approximation of Chew is applied to the calculation of the cross sections for rotational and vibrational excitation of diatomic molecules by collisions with an atom. The assumptions underlying the impulse approximation are discussed and found to be justified for these processes. A closure approximation is used to perform the sums over rotational quantum numbers in the expression for the vibrational-excitation cross section and the resulting expression depends on two factors; an oscillator form factor and the scattering amplitudes for atom-atom scattering. Vibrational-transition probabilities, evaluated for oxy-gen-carbon monoxide collisions assuming that the oscillator is harmonic and using a rough estimate for the typical atom-atom scattering amplitudes, are in qualitative agreement with experiment. Further refinements and extensions of the model are discussed.

## I. INTRODUCTION

The study of vibrational and rotational energy transfer in gases has occupied chemists and physicists since the 1930's. The various approaches to the calculation of transition probabilities have been reviewed by a number of authors. ${ }^{1-5}$ Recently, the impulse approximation of Chew ${ }^{6}$ has been brought to bear on one-dimensional atom-diatomicmolecule collisions by Clinton, Cosgrove, and Henderson ${ }^{7}$ and by Eckelt and Korsch. ${ }^{8}$ In this paper we apply the impulse approximation to threedimensional atom-diatomic-molecule collisions.

The assumptions underlying the impulse approximation are (1) the incident particle interacts with only one particle of the composite system at a time, (2) the amplitude of the incident wave falling upon constituents of the system is nearly the same as if that constituent were alone, and (3) binding forces between the constituents are negligible while the incident particle interacts strongly with the system. ${ }^{9-11}$ Quantitative criteria for assumptions 1 and 2 have proven elusive ${ }^{9-11}$; assumption 1 , however, seems justified when the range of the atom-diatomic-molecule interaction $R$ is much less than the interatomic spacing of the diatomic molecule $\tau_{e}$,

$$
\begin{equation*}
R \ll \tau_{e} \tag{1}
\end{equation*}
$$

and assumption 2 will be satisfied when

$$
\begin{equation*}
\sigma \ll 4 \pi \tau_{e}^{2}\left(k \tau_{e}\right)^{2} \tag{2}
\end{equation*}
$$

where $\sigma$ is the cross section and $k$ is the wave number of the incident atom. ${ }^{9}$
When the relative kinetic energy $E_{k}$ is well above the rotational threshold, the atom-diatomic-molecule interaction is predominately a short-range interaction and Eq. (1) will be satisfied. For example,

Herzfeld has shown that an exponential repulsive potential of the form $e^{-r / L}$ with $L \approx r_{c} / 17.5$ matches the Lennard-Jones 6-12 potential well for these energies where $r_{0}$ is the Lennard-Jones length parameter. ${ }^{12}$ If we identify $L$ with the range of the atom -diatomic-molecule interaction, Eq. (1) will be satisfied since $r_{0}$ and $\tau_{e}$ are of the same order of magnitude.

The cross section is of the same order of magnitude as $4 \pi \tau_{e}^{2}$, and Eq. (2) becomes

$$
E_{k} / h c \gg\left(\mu_{\tau} / \mu_{r}\right) B_{e}>B_{e}
$$

where $B_{e}=h /\left(8 \pi^{2} c \mu_{\tau} \tau_{e}^{2}\right)$ is the rotational term constant ${ }^{13}$ and $\mu_{\tau}$ and $\mu_{r}$ are the reduced masses for vibrational motion and relative motion. Assumption 2 will also be satisfied when the kinetic energy is well above the rotational threshold.

Assumption 3 is valid when the duration of the collision $\tau_{c}$ is small compared to the period of oscillation of the bound system. ${ }^{9}$ This is just the condition for the interaction to proceed so rapidly that the wave function cannot adjust itself adiabatically and implies that the transition probabilities will be appreciable. ${ }^{14}$ Typical rotational and vibrational periods are $10^{-10}$ and $10^{-13} \mathrm{sec}$. If we let the collision duration be $\tau_{c}=L / V$ and $L \sim 10^{-9} \mathrm{~cm}$, this assumption will be valid provided the relative velocity remains above $0.1 \mathrm{~km} / \mathrm{sec}$ for vibrational excitation and $10 \mathrm{~cm} / \mathrm{sec}$ for rotational excitation. All velocities of interest in molecular excitation are well above these limits except for the final relative velocities when the energy is just above a threshold.
We shall consider only vibrational excitation here so that assumptions 1 and 2 will be well satisfied and assumption 3 will be satisfied except near energy thresholds. The impulse approxima-
tion allows us to separate the vibrational part of the calculation from the scattering part. In Sec. II we derive the form that the impulse approximation takes for atom-diatomic-molecule scattering. The contribution of the molecular vibrations to the calculation is contained in a form factor that is discussed and calculated for a harmonic potential in Sec. III. In Sec. IV we discuss the scattering part of the calculation and present a sample calculation of the cross sections for the vibrational excitation of carbon monoxide by collision with atomic oxygen when both are in their electronic ground states. Since the ground state of atomic oxygen is a triplet state, the interaction will proceed along the potential curves for triplet $\mathrm{CO}_{2}$ which are all repulsive. ${ }^{15}$ We shall not consider possible contributions to this process from the crossing of the singlet and triplet $\mathrm{CO}_{2}$ potential curves. ${ }^{16}$
Before proceeding, we should mention that the "sudden" approximation is also claimed to be valid when assumption 3 is justified. ${ }^{17,18}$ In this approximation, the vibrational part of the calculation separates from the collision part, as in the impulse approximation, and the vibrational contribution to the interaction is contained in a form factor identical to ours. (In Treanor's one-dimensional theory as well, the same form factor appears. ${ }^{19}$ ) The essential differences between our approach and the sudden approximation are twofold. The first is that the scattering part is typically treated in a semiclassical manner in the sudden approximation, whereas our approach is in principle entirely quantum mechanical. In this paper we have used a rough estimate for the scattering amplitude, which is certainly no better than the semiclassical approach of the sudden approximation. We shall see, however, that our result does not depend strongly on this assumption, and an extension to a more realistic model is straightforward.

The other difference between these approximations is that the sudden approximation treats the scattering part of the interaction by letting the atom-diatomic-molecule potential be represented by a spherically averaged interaction and treating the residual interaction as a perturbation. In the impulse approximation, the atom-diatomic-molecule interaction is treated as the sum of twobody potentials between the incident atom and the constituents of the diatomic molecule and is handled exactly (subject to assumptions $1-3$ ). It is this second difference that we feel makes the impulse approximation preferable to the sudden approximation.

Our results are summarized and discussed in Sec. V.

## II. IMPULSE APPROXIMATION

We shall consider the scattering to be described by a Hamiltonian of the form

$$
\begin{align*}
H= & -\frac{\hbar^{2}}{2 m_{a}} \nabla_{a}^{2}-\frac{\hbar^{2}}{2 m_{b}} \nabla_{b}^{2}-\frac{\hbar^{2}}{2 m_{c}} \nabla_{c}^{2}+V_{1}\left(\left|\overrightarrow{\mathbf{r}}_{a}-\overrightarrow{\mathbf{r}}_{c}\right|\right) \\
& +V_{2}\left(\left|\overrightarrow{\mathrm{r}}_{a}-\overrightarrow{\mathrm{r}}_{b}\right|\right)+V_{B}\left(\left|\overrightarrow{\mathrm{r}}_{b}-\overrightarrow{\mathrm{r}}_{c}\right|\right) . \tag{3}
\end{align*}
$$

Although quantum-mechanical calculations of the potential for $\mathrm{H}_{2}+\mathrm{H}, \mathrm{H}_{2}+\mathrm{H}_{2}$, and $\mathrm{H}_{2}+\mathrm{He}$ show that the interaction is not, in general, a sum of two-body potentials, ${ }^{2}$ our knowledge of the true potential for heavier systems is so limited that this seems to be a reasonable choice for the present.

We may separate out the center-of-mass motion with the transformation to the center-of-mass system,

$$
\begin{align*}
& M \overrightarrow{\mathrm{R}}=m_{a} \overrightarrow{\mathrm{r}}_{a}+m_{b} \overrightarrow{\mathrm{r}}_{b}+m_{c} \overrightarrow{\mathrm{r}}_{c},  \tag{4}\\
& \overrightarrow{\mathrm{r}}=\overrightarrow{\mathrm{r}}_{a}-\left(m_{b} \overrightarrow{\mathrm{r}}_{b}+m_{c} \overrightarrow{\mathrm{r}}_{c}\right) /\left(m_{b}+m_{c}\right), \tag{5}
\end{align*}
$$

and

$$
\begin{equation*}
\vec{\tau}=\overrightarrow{\mathrm{r}}_{b}-\overrightarrow{\mathrm{r}}_{c}, \tag{6}
\end{equation*}
$$

where $M=\left(m_{a}+m_{b}+m_{c}\right)$. The momenta conjugate to these coordinates are

$$
\begin{aligned}
& \overrightarrow{\mathrm{K}}=\overrightarrow{\mathrm{k}}_{a}+\overrightarrow{\mathrm{k}}_{b}+\overrightarrow{\mathrm{k}}_{c}, \quad M \overrightarrow{\mathrm{k}}_{r}=\left(m_{b}+m_{c}\right) \overrightarrow{\mathrm{k}}_{a}-m_{a}\left(\overrightarrow{\mathrm{k}}_{b}+\overrightarrow{\mathrm{k}}_{c}\right), \\
& \left(n_{b}+m_{c}\right) \overrightarrow{\mathrm{k}}_{\tau}=m_{c} \overrightarrow{\mathrm{k}}_{b}-m_{b} \overrightarrow{\mathrm{k}}_{c}
\end{aligned}
$$

and the Hamiltonian is

$$
\begin{align*}
H(\overrightarrow{\mathrm{R}}, \overrightarrow{\mathrm{r}}, \vec{\tau})= & -\frac{\hbar^{2}}{2 M} \nabla_{R}^{2}+H_{0}(\overrightarrow{\mathrm{r}}, \vec{\tau}) \\
& +V_{b}\left(\left|\overrightarrow{\mathrm{r}}+\beta_{b} \vec{\tau}\right|\right)+V_{c}\left(\left|\overrightarrow{\mathrm{r}}+\beta_{c} \vec{\tau}\right|\right), \tag{7}
\end{align*}
$$

where

$$
\begin{equation*}
H_{0}(\overrightarrow{\mathrm{r}}, \vec{\tau})=-\frac{\hbar^{2}}{2 \mu_{r}} \nabla_{r}^{2}-\frac{\hbar^{2}}{2 \mu_{\tau}} \nabla_{\tau}^{2}+V_{B}(|\vec{\tau}|), \tag{8}
\end{equation*}
$$

and where $\mu_{r}=m_{a}\left(m_{b}+m_{c}\right) / M, \mu_{\tau}=m_{b} m_{c} /\left(m_{b}+m_{c}\right)$, $\beta_{b}=-m_{c} /\left(m_{b}+m_{c}\right)$, and $\beta_{c}=m_{b} /\left(m_{b}+m_{c}\right)$.

The $R$ dependence of Schrödinger's equation

$$
\begin{equation*}
H \Psi(\overrightarrow{\mathrm{R}}, \overrightarrow{\mathrm{r}}, \vec{\tau})=E \Psi(\overrightarrow{\mathrm{R}}, \overrightarrow{\mathrm{r}}, \vec{\tau}) \tag{9}
\end{equation*}
$$

may be factored

$$
\begin{equation*}
\Psi(\overrightarrow{\mathrm{R}}, \overrightarrow{\mathrm{r}}, \vec{\tau})=e^{i \overrightarrow{\mathrm{~K}} \cdot \overrightarrow{\mathrm{R}}} \psi(\overrightarrow{\mathrm{r}}, \vec{\tau}) \tag{10}
\end{equation*}
$$

where $\psi(\vec{r}, \vec{\tau})$ is a solution of

$$
\begin{array}{r}
{\left[H_{0}(\overrightarrow{\mathrm{r}}, \vec{\tau})+V_{b}\left(\left|\overrightarrow{\mathrm{r}}+\beta_{b} \vec{\tau}\right|\right)+V_{c}\left(\left|\overrightarrow{\mathrm{r}}+\beta_{c} \vec{\tau}\right|\right)\right] \psi(\overrightarrow{\mathrm{r}}, \vec{\tau})} \\
=E^{\prime} \psi(\overrightarrow{\mathrm{r}}, \vec{\tau}) \tag{11}
\end{array}
$$

and where

$$
\begin{equation*}
E^{\prime}=E-\hbar^{2} K^{2} / 2 M \tag{12}
\end{equation*}
$$

The solutions of Eq. (11) appropriate to the scattering of a plane wave in the $z$ direction of atom $a$
by a bound state of molecule $b c$ at rest with quantum numbers $n_{0}, l_{0}$, and $m_{0}$ satisfy the integral equation ${ }^{20,21}$

$$
\begin{align*}
\psi(\overrightarrow{\mathrm{r}}, \vec{\tau})= & e^{i k_{r} z} \varphi_{n_{0}, l_{0}, m_{0}}(\vec{\tau})+\sum_{n, l, m} \psi_{n, l, m}(\overrightarrow{\mathbf{r}}, \vec{\tau}),  \tag{13}\\
\psi_{n, l, m}(\overrightarrow{\mathbf{r}}, \vec{\tau})= & -\frac{2 \mu_{r}}{4 \pi \hbar^{2}} \int d \overrightarrow{\mathbf{r}}^{\prime} \int d \vec{\tau}^{\prime} \\
& \times \varphi_{n, l, m}(\vec{\tau}) \frac{e^{i k_{r}^{\prime}\left|\vec{r}^{\prime}-\overrightarrow{\mathrm{r}}\right|}}{\left|\overrightarrow{\mathbf{r}}^{\prime}-\overrightarrow{\mathbf{r}}\right|} \varphi_{n, l, m}^{*}\left(\vec{\tau}^{\prime}\right) \\
& \times\left[V_{b}\left(\left|\overrightarrow{\mathbf{r}}^{\prime}+\beta_{b} \vec{\tau}^{\prime}\right|\right)+V_{c}\left(\left|\overrightarrow{\mathrm{r}}^{\prime}+\beta_{c} \vec{\tau}^{\prime}\right|\right)\right] \psi\left(\overrightarrow{\mathrm{r}}^{\prime}, \overrightarrow{\mathrm{T}}^{\prime}\right), \tag{14}
\end{align*}
$$

where the functions $\varphi_{n, t, m}(\vec{\tau})$ are the solutions of the equation

$$
\begin{equation*}
\left(-\frac{\hbar^{2}}{2 \mu_{\tau}} \nabla_{\tau}^{2}+V_{B}(|\vec{\tau}|)\right) \varphi_{n, l, m}(\vec{\tau})=\epsilon_{n, l} \varphi_{n, l, m}(\vec{\tau}), \tag{15}
\end{equation*}
$$

$n, l$, and $m$ are the final quantum numbers of the bound states, and

$$
\begin{equation*}
k_{r}^{\prime 2}=2 \mu_{r}\left(E^{\prime}-\epsilon_{n, b}\right) / \hbar^{2} . \tag{16}
\end{equation*}
$$

The sum on $n, l$, and $m$ in Eq. (13) represents a sum over all discrete quantum numbers and an integral over all continuous quantum numbers.

We note that there is a contribution to the integral in Eq. (14) only from regions of $\overrightarrow{\mathbf{r}}^{\prime}, \vec{\tau}^{\prime}$ space where the potential is appreciable. When $|\vec{r}|$ is outside this domain, we have

$$
\psi_{n, l, m}(\overrightarrow{\mathrm{r}}, \vec{\tau}) \rightarrow \frac{e^{i \boldsymbol{k}_{r}^{\prime} r}}{r} \varphi_{n, l, m}(\vec{\tau}) f_{n, l, m}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)
$$

as $r \rightarrow \infty$
where

$$
\begin{align*}
f_{n, l, m}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)= & -\frac{2 \mu_{r}}{4 \pi \hbar^{2}} \int d \overrightarrow{\mathbf{r}}^{\prime} \int d \vec{\tau}^{\prime} e^{-i \overrightarrow{\vec{k}}_{r}^{\prime} \cdot \vec{r}^{\prime}} \varphi_{n, l, m}^{*}\left(\vec{\tau}^{\prime}\right) \\
& \times\left[V_{b}\left(\left|\overrightarrow{\mathbf{r}}^{\prime}+\beta_{b} \vec{\tau}^{\prime}\right|\right)+V_{c}\left(\left|\overrightarrow{\mathbf{r}}^{\prime}+\beta_{c} \vec{\tau}^{\prime}\right|\right)\right] \psi\left(\overrightarrow{\mathbf{r}}^{\prime}, \vec{\tau}^{\prime}\right) \tag{17}
\end{align*}
$$

and where $\overrightarrow{\mathrm{k}}_{r}^{\prime}$ is a vector in the $\overrightarrow{\mathrm{r}}$ direction with magnitude $k_{r}^{\prime}$. The differential cross section for excitation of the level $n, l, m$ is given by ${ }^{20,21}$

$$
\begin{equation*}
\sigma(\theta, \varphi)=\left(k_{a}^{f} / k_{a}\right)\left|f_{n, l, m}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)\right|^{2} \tag{18}
\end{equation*}
$$

where $k_{a}^{f}=\left|\overrightarrow{\mathrm{k}}_{r}^{\prime}+m_{a} \overrightarrow{\mathrm{k}}_{a} / M\right|$.
The expression for the scattering amplitude in Eq. (17) is exact, but can be calculated only if the true wave function $\psi\left(\vec{r}^{\prime}, \vec{\tau}^{\prime}\right)$ is known. In the Born approximation one assumes that the scattering is weak, and one lets $\psi\left(\vec{r}^{\prime}, \vec{\tau}^{\prime}\right)=e^{i k_{r} z^{\prime}} \varphi_{n_{0}}, \imath_{0, m_{0}}\left(\vec{\tau}^{\prime}\right)$ in Eq. (17). This procedure will not work in the case considered here because of the strongly repulsive
nature of $V_{1}$ and $V_{2}$.
In the impulse approximation of Chew, the scattering amplitude is separated;

$$
\begin{equation*}
f_{\mathrm{IA}}\left(\mathrm{k}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)=f_{b}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)+f_{c}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right), \tag{19}
\end{equation*}
$$

where

$$
\begin{align*}
f_{i}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)= & -\frac{2 \mu_{r}}{4 \pi \hbar^{2}} \int d \overrightarrow{\mathrm{r}}^{\prime} \int d \vec{\tau}^{\prime} e^{-\overrightarrow{\mathrm{k}_{r}^{\prime}} \cdot \overrightarrow{\mathrm{r}}^{\prime}} \varphi_{n, i, m}^{*}\left(\vec{\tau}^{\prime}\right) \\
& \times V_{i}\left(\left|\overrightarrow{\mathrm{r}}+\beta_{i} \vec{\tau}\right|\right) \psi_{i}\left(r^{\prime}, \tau^{\prime}\right) \tag{20}
\end{align*}
$$

and the wave function $\psi_{i}(\vec{r}, \vec{\tau})$ is approximated by the exact expression for the scattering of atom $a$ with momentum $\overrightarrow{\mathrm{k}}_{a}$ by atom $i$ with momentum $\overrightarrow{\mathrm{k}}_{i}$ in the center-of-mass system, ignoring the presence of the other atom of the molecule except to average $\vec{k}_{b}$ and $\vec{k}_{c}$ over their momentum distribution in the initial state ${ }^{6}$; that is, for the case when the molecule is initially at rest,

$$
\begin{align*}
\psi_{c}\left(\overrightarrow{\mathrm{r}}_{a}, \overrightarrow{\mathrm{r}}_{b}, \overrightarrow{\mathrm{r}}_{c}\right)= & (2 \pi)^{-3 / 2} \int d \overrightarrow{\mathrm{k}}_{b} \int d \overrightarrow{\mathrm{k}}_{c} \\
& \times e^{i\left(\overrightarrow{\mathrm{k}}_{b} \cdot \overrightarrow{\mathrm{r}}_{b}-\overrightarrow{\mathrm{k}}_{a} \cdot \overrightarrow{\mathrm{R}}\right) G_{0}\left(\overrightarrow{\mathrm{k}}_{b}, \overrightarrow{\mathrm{k}}_{c}\right) \Phi_{\overrightarrow{\mathrm{k}}_{a}}, \overrightarrow{\mathrm{k}}_{c}\left(\overrightarrow{\mathrm{r}}_{a}, \overrightarrow{\mathrm{r}}_{c}\right),} \tag{21}
\end{align*}
$$

where

$$
\begin{align*}
G_{0}\left(\overrightarrow{\mathrm{k}}_{b}, \overrightarrow{\mathrm{k}}_{c}\right)= & (2 \pi)^{-3} \int d \overrightarrow{\mathrm{r}}_{b} \int d \overrightarrow{\mathrm{r}}_{c} \\
& \times e^{-i\left(\overrightarrow{\mathrm{k}}_{b} \cdot \overrightarrow{\mathrm{r}}_{b}+\overrightarrow{\mathrm{k}}_{c} \cdot \overrightarrow{\mathrm{r}}_{c}\right)} \varphi_{n_{0}, l_{0}, m_{0}}\left(\overrightarrow{\mathrm{r}}_{b}-\overrightarrow{\mathrm{r}}_{c}\right) \tag{22}
\end{align*}
$$

and where $\Phi \vec{k}_{a}, \vec{k}_{c}\left(\vec{r}_{a}, \overrightarrow{\mathrm{r}}_{c}\right)$ is the exact wave function for the scattering of atom $a$ with momentum $\overrightarrow{\mathrm{K}}_{a}$ by atom $c$ with momentum $\overrightarrow{\mathrm{k}}_{c}$. The factor $e^{-\mathrm{k}_{a} \cdot \mathrm{R}}$ in Eq. (21) removes the center-of-mass motion from the wave function. The expression for $G_{0}\left(\vec{k}_{b}, \vec{k}_{c}\right)$ may be simplified;

$$
\begin{align*}
G_{0}\left(\overrightarrow{\mathbf{k}}_{b}, \overrightarrow{\mathrm{k}}_{c}\right) & =\delta\left(\overrightarrow{\mathrm{k}}_{b}+\overrightarrow{\mathrm{k}}_{c}\right) g_{0}\left(\frac{m_{c} \overrightarrow{\mathrm{k}}_{b}-m_{b} \overrightarrow{\mathbf{k}}_{c}}{m_{b}+m_{c}}\right) \\
& =\int d \overrightarrow{\mathbf{k}}_{\tau} g_{0}\left(\overrightarrow{\mathrm{k}}_{\tau}\right) \delta\left(\overrightarrow{\mathrm{k}}_{\tau}-\overrightarrow{\mathrm{k}}_{b}\right) \delta\left(\overrightarrow{\mathrm{k}}_{\tau}+\overrightarrow{\mathrm{k}}_{c}\right) \tag{23}
\end{align*}
$$

where

$$
\begin{equation*}
g_{0}\left(\overrightarrow{\mathrm{k}}_{\mathrm{T}}\right)=(2 \pi)^{-3 / 2} \int d \vec{\tau} e^{-i \overrightarrow{\mathrm{k}}_{T} \cdot \vec{\tau}} \varphi_{n_{0}, l_{0}, m_{0}}(\vec{\tau}) . \tag{24}
\end{equation*}
$$

The expression for $\Phi_{\vec{k}_{a}}, \vec{k}_{c}\left(\overrightarrow{\mathrm{r}}_{a}, \overrightarrow{\mathrm{r}}_{c}\right)$ is also simplified in the $a-c$ center-of-mass system

$$
\begin{equation*}
\overrightarrow{\mathrm{R}}_{a c}=\frac{m_{a}}{m_{a}+m_{c}} \overrightarrow{\mathbf{r}}_{a}+\frac{m_{c}}{m_{a}+m_{c}} \overrightarrow{\mathrm{r}}_{c} \tag{25}
\end{equation*}
$$

and

$$
\begin{equation*}
\vec{\rho}=\overrightarrow{\mathbf{r}}_{a}-\overrightarrow{\mathbf{r}}_{c}, \tag{26}
\end{equation*}
$$

with the conjugate momenta

$$
\begin{equation*}
\overrightarrow{\mathrm{k}}_{a c}=\overrightarrow{\mathrm{k}}_{a}+\overrightarrow{\mathrm{k}}_{c} \tag{27}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(m_{a}+m_{c}\right) \overrightarrow{\mathbf{k}}_{\rho}=m_{c} \overrightarrow{\mathbf{k}}_{a}-m_{a} \overrightarrow{\mathbf{k}}_{\dot{\prime}} ; \tag{28}
\end{equation*}
$$

$$
\begin{equation*}
\Phi_{\overrightarrow{\mathrm{k}}_{a}}, \overrightarrow{\mathrm{k}}_{c}\left(\overrightarrow{\mathrm{r}}_{a}, \overrightarrow{\mathrm{r}}_{c}\right)=e^{i \overrightarrow{\mathrm{k}}_{a c} \cdot \overrightarrow{\mathrm{R}}_{a c}} \chi_{\overrightarrow{\mathrm{k}}_{\rho}}^{(c)}(\vec{\rho}) . \tag{29}
\end{equation*}
$$

When Eqs. (23) and (29) are substituted into Eq. (21) we have
$\psi_{c}\left(\overrightarrow{\mathbf{r}}_{a}, \overrightarrow{\mathbf{r}}_{b}, \overrightarrow{\mathbf{r}}_{c}\right)=(2 \pi)^{-3 / 2} \int d \overrightarrow{\mathbf{k}}_{\tau} g_{0}\left(\overrightarrow{\mathrm{k}}_{\tau}\right) \chi_{\mathrm{k}_{\rho}}^{(c)}(\vec{\rho}) \exp \left\{i\left[\overrightarrow{\mathrm{k}}_{\tau} \cdot \overrightarrow{\mathbf{r}}_{b}-\overrightarrow{\mathrm{k}}_{a} \cdot \overrightarrow{\mathrm{R}}+\left(\overrightarrow{\mathbf{k}}_{a}-\overrightarrow{\mathrm{k}}_{\tau}\right) \cdot\left(m_{a} \overrightarrow{\mathbf{r}}_{a}+m_{c} \overrightarrow{\mathbf{r}}_{c}\right) /\left(m_{a}+m_{c}\right)\right]\right\}$,
where

$$
\begin{equation*}
\overrightarrow{\mathrm{k}}_{\rho}=\left(m_{c} \overrightarrow{\mathrm{k}}_{a}+m_{a} \overrightarrow{\mathrm{k}}_{\tau}\right) /\left(m_{a}+m_{c}\right) . \tag{31}
\end{equation*}
$$

We now may use the inverse of the transformation in Eqs. (4)-(6),

$$
\begin{align*}
& \overrightarrow{\mathbf{r}}_{a}=\overrightarrow{\mathrm{R}}+\left(m_{b}+m_{c}\right) \overrightarrow{\mathbf{r}} / M  \tag{32}\\
& \overrightarrow{\mathrm{r}}_{b}=\overrightarrow{\mathrm{R}}-m_{a} \overrightarrow{\mathrm{r}} / M+m_{c} \vec{\tau} /\left(m_{b}+m_{c}\right),
\end{align*}
$$

and

$$
\overrightarrow{\mathbf{r}}_{c}=\overrightarrow{\mathrm{R}}-m_{a} \overrightarrow{\mathbf{r}} / M-m_{b} \vec{\tau} /\left(m_{b}+m_{c}\right),
$$

to express $\psi_{c}$ in terms of $\vec{\rho}$ and $\overrightarrow{\boldsymbol{\tau}}$;
$\psi_{c}(\overrightarrow{\mathbf{r}}, \vec{\tau})=(2 \pi)^{-3 / 2} \int d \overrightarrow{\mathbf{k}}_{\tau} g_{0}\left(\overrightarrow{\mathbf{k}}_{\tau}\right) \chi_{\overrightarrow{\mathrm{k}}_{\rho}}^{(c)}(\vec{\rho})$

$$
\times \exp \left\{i\left(\overrightarrow{\mathrm{k}}_{\tau}-m_{b} \overrightarrow{\mathbf{k}}_{a} / M\right) \cdot\left[\vec{\tau}-m_{a} \vec{\rho} /\left(m_{a}+m_{c}\right)\right]\right\},
$$

since $\overrightarrow{\mathbf{r}}=\vec{\rho}-m_{b} \vec{\tau} /\left(m_{b}+m_{c}\right)$. When $\overrightarrow{\mathrm{k}}_{b}+\overrightarrow{\mathrm{k}}_{c}=0$, we have

$$
\begin{equation*}
\overrightarrow{\mathrm{k}}_{a}=M \overrightarrow{\mathrm{k}}_{r} /\left(m_{b}+m_{c}\right), \tag{33}
\end{equation*}
$$

and so the expression (20) for the partial scattering amplitude becomes

$$
\begin{align*}
f_{c}\left(\overrightarrow{\mathbf{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)= & -\frac{2 \mu_{r}}{4 \pi \hbar^{2}}(2 \pi)^{-3 / 2} \int d \overrightarrow{\mathbf{k}}_{\tau} g_{0}\left(\overrightarrow{\mathrm{k}}_{\tau}\right) \int d \vec{\tau} \exp \left(i \vec{\tau} \cdot\left\{\overrightarrow{\mathrm{k}}_{\tau}+\left[m_{b} /\left(m_{b}+m_{c}\right)\right] \overrightarrow{\mathrm{q}}\right\}\right) \varphi_{n, t, m}^{*}(\vec{\tau}) \\
& \times \int d \vec{\rho} e^{-i \vec{\rho} \cdot\left(\overrightarrow{\mathrm{k}}_{\rho}+\overrightarrow{\mathrm{q}}\right)} V_{c}(|\vec{\rho}|) x_{\overrightarrow{\mathrm{k}}_{\rho}}^{(c)}(\vec{\rho}), \tag{34}
\end{align*}
$$

where

$$
\begin{equation*}
\overrightarrow{\mathrm{q}} \equiv \overrightarrow{\mathrm{k}}_{r}^{\prime}-\overrightarrow{\mathrm{k}}_{r} . \tag{35}
\end{equation*}
$$

Equation (34) and the similar expression for $f_{b}\left(\overrightarrow{\mathbf{k}}_{r}^{\prime}, \vec{k}_{r}\right)$,

$$
\begin{align*}
& f_{b}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)=-\frac{2 \mu_{r}}{4 \pi \hbar^{2}}(2 \pi)^{-3 / 2} \int d \overrightarrow{\mathrm{k}}_{\tau} g_{0}\left(\overrightarrow{\mathrm{k}}_{\tau}\right) \int d \vec{\tau} \exp \left(i \vec{\tau} \cdot\left\{\overrightarrow{\mathrm{k}}_{\tau}-\left[m_{c} /\left(m_{b}+m_{c}\right)\right] \overrightarrow{\mathrm{q}}\right\}\right) \varphi_{n, i, m}^{*}(\vec{\tau}) \\
&\left.\times \int d \vec{\rho}^{\prime} e^{-i \vec{\rho}^{\prime} \cdot(\overrightarrow{\mathrm{k}}}{ }_{\rho}^{\prime}+\overrightarrow{\mathrm{q}}\right)  \tag{36}\\
& V_{b}\left(\left|\vec{\rho}^{\prime}\right|\right) \chi_{\overrightarrow{\mathrm{k}}_{\rho}^{\prime}}^{(b)}(\vec{\rho})
\end{align*}
$$

where

$$
\begin{equation*}
\left(m_{a}+m_{b}\right) \overrightarrow{\mathbf{k}}_{\rho}^{\prime}=m_{b} \overrightarrow{\mathbf{k}}_{a}-m_{a} \overrightarrow{\mathbf{k}}_{\tau}, \tag{37}
\end{equation*}
$$

constitute the impulse approximation to the di-atomic-molecule scattering amplitude.
All the quantities in Eqs. (34) and (36) may be calculated directly. Chew ${ }^{6}$ has pointed out that since these equations (i) reduce to the Born approximation when $\chi_{\vec{k}_{\rho}}(\vec{\rho})$ is approximated by $e^{i \vec{k}_{\rho} \cdot \stackrel{\rightharpoonup}{\rho}}$ and (ii) give the exact expression for scattering when the binding potential $V_{B}(|\vec{\tau}|)$ is neglected, they may be viewed as an interpolation between these limits.
The function $g_{0}\left(\vec{k}_{T}\right)$ becomes vanishingly small for $\overrightarrow{\mathrm{k}}_{\tau}>L^{-1}$, where $L$ is the size of the target. Whenever $\left|\overrightarrow{\mathrm{k}}_{a}\right| \gg m_{a} R^{-1} / m_{c}$ (and $k_{a} \gg m_{a} R^{-1} / m_{b}$ ), we may neglect the dependence of $\overrightarrow{\mathrm{k}}_{\rho}$ (and $\overrightarrow{\mathrm{k}}_{\rho}^{\prime}$ ) upon $\overrightarrow{\mathrm{k}}_{\tau}$ and factor Eqs. (34) and (36);

$$
\begin{align*}
f_{c}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)= & \left(\mu_{r} / \mu_{a c}\right) \tilde{f}_{c}\left(\left(\mu_{a c} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}+\overrightarrow{\mathrm{q}},\left(\mu_{a c} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}\right) \\
& \times \mathcal{F}_{n, l, m ; n_{0}, b_{0}, m_{0}}\left(-m_{b} \overrightarrow{\mathrm{q}} /\left(m_{b}+m_{c}\right)\right) \tag{38}
\end{align*}
$$

and

$$
\begin{align*}
f_{b}\left(\overrightarrow{\mathrm{k}}_{r}^{\prime}, \overrightarrow{\mathrm{k}}_{r}\right)= & \left(\mu_{\boldsymbol{r}} / \mu_{a b}\right) \tilde{f}_{b}\left(\left(\mu_{a b} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{\boldsymbol{r}}+\overrightarrow{\mathrm{q}},\left(\mu_{a b} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}\right) \\
& \times \mathfrak{F}_{n, l, m ; n_{0}, b_{b}, m_{0}}\left(m_{c} \overrightarrow{\mathrm{q}} /\left(m_{b}+m_{c}\right)\right), \tag{39}
\end{align*}
$$

where we have introduced the reduced masses

$$
\begin{equation*}
\mu_{a c} \equiv m_{a} m_{c} /\left(m_{a}+m_{c}\right) \tag{40}
\end{equation*}
$$

and

$$
\mu_{a b} \equiv m_{a} m_{b} /\left(m_{a}+m_{b}\right),
$$

the bound-state form factor

$$
\begin{equation*}
\mathcal{F}_{n, l, m ; n_{0}, l l_{0} m_{0}}(\vec{\kappa}) \equiv \int d \tau e^{-i \vec{\kappa} \cdot \vec{\tau}} \varphi_{n, l, m}^{*}(\vec{\tau}) \varphi_{n_{0}, l_{0}, m_{0}}(\vec{\tau}), \tag{41}
\end{equation*}
$$

and the free scattering amplitudes

$$
\begin{equation*}
\tilde{f}_{i}\left(\overrightarrow{\mathrm{k}}_{2}, \overrightarrow{\mathrm{k}}_{1}\right) \equiv-\left(2 \mu_{a i} / 4 \pi \hbar^{2}\right) \int d \vec{\rho} e^{-i \overrightarrow{\mathrm{k}}_{2} \cdot \vec{\rho}} V_{i}(\rho)_{\chi_{\overrightarrow{\mathrm{k}}_{i}}^{(i)}}^{(\rho)} \tag{42}
\end{equation*}
$$

## III. BOUND-STATE FORM FACTOR

A number of interesting properties of the boundstate form factor follow immediately from its definition (41). Since the bound-state wave functions are orthonormal, we have

$$
\begin{equation*}
\mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}(0)=\hat{\delta}_{n, n_{0}} \hat{o}_{l, l_{0}} \bar{o}_{m, m_{0}} . \tag{43}
\end{equation*}
$$

Also, since the bound-state wave functions are complete, we may identify $\mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}(\vec{\kappa})$ as the coefficient of $\varphi_{n, l, m}(\tau)$ in an expansion of $e^{-i \vec{k} \cdot \bar{\tau}}$ $\times \varphi_{n_{0}, l_{0}, m_{0}}(\vec{\tau})$;

$$
e^{-i \vec{\kappa} \cdot \vec{\tau}} \varphi_{n_{0}, l_{0}, m_{0}}(\vec{\tau})=\sum_{n, l, m} \mathcal{F}_{n, l, m: n_{0}, l_{0}, m_{0}}(\vec{\kappa}) \varphi_{n, l, m}(\vec{\tau}),
$$

where the sum on $n, l$, and $m$ represents a sum over all discrete quantum numbers and an integral over all continuous quantum numbers. If we multiply this by the similar expression for $e^{i \vec{k} \cdot \vec{\tau}}$ $\times \varphi_{n_{1}, l_{1}, m_{1}}^{*}(\vec{\tau})$ and integrate over $\vec{\tau}$, we have
$\delta_{n_{0}, n_{1}} \dot{\delta}_{l_{0}, l_{1}} \delta_{m_{0}, m_{1}}$

$$
\begin{equation*}
=\sum_{n, l, m} \mathcal{F}_{n, l, m: n_{0}, l_{0}, m_{0}}(\vec{\kappa}) \mathcal{F}{ }_{n, l, m ; n_{1}, l_{1}, m_{1}}^{*}(\vec{\kappa}) \tag{44}
\end{equation*}
$$

and, in particular,

$$
\begin{equation*}
\sum_{n, l, m}\left|\mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}(\kappa)\right|^{2}=1 \tag{45}
\end{equation*}
$$

Let us now approximate the binding potential with a harmonic-oscillator potential

$$
\begin{equation*}
V_{B}(|\vec{\tau}|)=\frac{1}{2} \mu_{\tau} \omega_{0}^{2}\left(\tau-\tau_{e}\right)^{2} . \tag{46}
\end{equation*}
$$

The solutions of Eq. (15) are of the form

$$
\begin{equation*}
\varphi_{n, l, m}(\vec{\tau})=\tau^{-1} U_{n l}(\xi) Y_{l m}\left(\theta_{\tau}, \varphi_{\tau}\right), \tag{47}
\end{equation*}
$$

where

$$
\begin{align*}
& \xi \equiv\left(\tau-\tau_{e}\right) / \sqrt{2} d,  \tag{48}\\
& d \equiv\left(\hbar / 2 \omega_{0} \mu_{\tau}\right)^{1 / 2}, \tag{49}
\end{align*}
$$

and

$$
\begin{equation*}
\xi_{e} \equiv \tau_{e} / \sqrt{2} d \tag{50}
\end{equation*}
$$

and where $U_{n l}(\xi)$ satisfies the differential equation

$$
\begin{equation*}
\frac{\partial^{2}}{\partial \xi^{2}} U_{n l}(\xi)+\left(\frac{2 \epsilon_{n l}}{\hbar \omega_{0}}-\frac{l(l+1)}{\left(\xi+\xi_{e}\right)^{2}}-\xi^{2}\right) U_{n l}(\xi)=0 \tag{51}
\end{equation*}
$$

for $-\xi_{e}<\xi<\infty$ with the boundary conditions

$$
\begin{equation*}
U_{n l}\left(-\xi_{e}\right)=0 \tag{52}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{\xi \rightarrow \infty} U_{n l}(\xi)=0 \tag{53}
\end{equation*}
$$

The quantity $2 \xi_{e}^{2}$ may be recognized as the ratio of the vibrational level spacing to the rotational constant and is large for most diatomic molecules [for CO, $\xi_{e}=\left(\omega_{e} / 2 B_{e}\right)^{1 / 2}=23.7$ ]. ${ }^{13}$ We now make the approximation

$$
\begin{equation*}
-l(l+1) /\left(\xi+\xi_{e}\right)^{2} \approx-l(l+1) / \xi_{e}^{2} \tag{54}
\end{equation*}
$$

and let the boundary condition (52) become

$$
\begin{equation*}
\lim _{\xi \rightarrow-\infty} U_{n l}(\xi)=0 \tag{55}
\end{equation*}
$$

The radial wave function $U_{n i}(\xi)$ is then given by

$$
\begin{equation*}
U_{n i}(\xi)=N_{n} H_{n}(\xi) e^{-(1 / 2) \xi^{2}} \tag{56}
\end{equation*}
$$

where $n$ is an integer,

$$
\begin{equation*}
2 n+1=\frac{2 \epsilon_{n l}}{\hbar \omega_{0}}-\frac{l(l+1)}{\xi_{e}^{2}}, \tag{57}
\end{equation*}
$$

$H_{n}(\xi)$ is a Hermite polynomial, ${ }^{22}$ and the normalization constant $N_{n}$ is given by

$$
\begin{equation*}
N_{n}=\left[\omega_{0} \mu_{\tau} / \hbar \pi 2^{2 n}(n!)^{2}\right]^{1 / 4} . \tag{58}
\end{equation*}
$$

The approximations (54) and (55) are conventional in the treatment of diatomic-molecule spectra. Approximation (54) is equivalent to neglecting coupling between rotation and vibration. The solutions of

$$
\begin{equation*}
\frac{\partial^{2}}{\partial \xi^{2}} D_{n}(\sqrt{2} \xi)+\left(2 n+1-\xi^{2}\right) D_{n}(\sqrt{2} \xi)=0 \tag{59}
\end{equation*}
$$

which are bounded as $\xi \rightarrow+\infty$ are all pazabolic cylinder functions. ${ }^{23}$ The approximation (55) restricts $n$ to be zero or a positive integer, in which case $D_{n}(\sqrt{2} \xi)$ reduces to the product of an exponential and a Hermite polynomial as in Eq. (56). When the lower boundary condition is given by Eq. (52) and $\xi_{e}$ is large, it can be shown that $n$ must be slightly greater than an integer; however, the error in the energy eigenvalue associated with the approximation (55) is less than the error associated with the neglect of anharmonic terms in the potential.
When the bound wave functions are given by Eqs. (47) and (56), the form factor $\mathcal{F}_{n, t, m ; n_{0}, i_{0}, m_{0}}(\vec{\kappa})$ is

$$
\begin{align*}
\mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}(\vec{\kappa})= & \sum_{L, M}\left[4 \pi(2 l+1)\left(2 l_{0}+1\right)(2 L+1)\right]^{1 / 2} i^{-L}(-1)^{m}\left(\begin{array}{ccc}
l & l_{0} & L \\
-m & m_{0} & M
\end{array}\right)\left(\begin{array}{ccc}
l & l_{0} & L \\
0 & 0 & 0
\end{array}\right) Y_{L M}^{*}\left(\theta_{\kappa}, \varphi_{\kappa}\right) \\
& \times \int_{-\infty}^{\infty} d \xi H_{n}(\xi) H_{n_{0}}(\xi) e^{-\xi^{2}} N_{n} N_{n_{0}} \sqrt{2} d j_{L}\left(\sqrt{2} \kappa d\left(\xi+\xi_{e}\right)\right), \tag{60}
\end{align*}
$$

where we have expanded $e^{i \overrightarrow{\mathrm{k}} \cdot \vec{\tau}}$ in spherical harmonics and made use of the properties of spherical harmonics and $3-j$ symbols [such as $\left.\left(\begin{array}{cc}c_{1}^{2} & i_{0} \\ -m_{0} & L\end{array}\right)\right] .{ }^{24}$ In the expression for the inelastic cross section we require the square of the magnitude of the form factor to be averaged over the initial magnetic quantum numbers and summed over the final magnetic quantum numbers;

$$
\begin{align*}
& \frac{1}{\left(2 l_{0}+1\right)} \sum_{m, m_{0}}\left|\mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}(\vec{\kappa})\right|^{2} \\
& \left.\quad=\sum_{L}(2 L+1)(2 l+1)\left(\begin{array}{ccc}
l & l_{0} & L \\
0 & 0 & 0
\end{array}\right)^{2} \right\rvert\,\left(\pi 2^{n+n_{0}} n!n_{0}!\right)^{-1 / 2} \\
& \quad \times\left.\int_{-\infty}^{\infty} d \xi H_{n}(\xi) H_{n_{0}}(\xi) e^{-\xi^{2}} j_{L}\left(\sqrt{2} \kappa d\left(\xi+\xi_{e}\right)\right)\right|^{2} \tag{61}
\end{align*}
$$

where we have again used angular momentum identities.

The expression in Eq. (61) is suitable for calculations of rotational- and vibrational-excitation
cross sections. If we are interested only in the excitation of vibrational levels, we may sum this expression over the final orbital angular momentum $l$. An additional complication here is that $\epsilon_{n l}$, and hence $k_{r}^{\prime}, \tilde{f}_{c}\left(\overrightarrow{\mathbf{k}}_{\rho}^{f}, \overrightarrow{\mathrm{k}}_{\rho}\right)$, and $\tilde{f}_{b}\left(\overrightarrow{\mathrm{k}}_{\rho}^{f^{\prime}}, \overrightarrow{\mathrm{k}}_{\rho}^{\prime}\right)$, all depend upon $l$. Fortunately, the dependence of $\epsilon_{n l}$ upon $l$ is weak;

$$
\begin{equation*}
\epsilon_{n l}=\left(n+\frac{1}{2}\right) \hbar \omega_{0}+l(l+1) \hbar \omega_{0} / 2 \xi_{e}^{2} \approx\left(n+\frac{1}{2}\right) \hbar \omega_{0} \tag{62}
\end{equation*}
$$

and may be neglected to a good approximation since the integral in Eq. (61) vanishes for large $L$. With the approximation (60), we may use the closure property of the $3-j$ symbols

$$
\sum_{i}(2 l+1)\left(\begin{array}{lll}
l & l_{0} & L \\
0 & 0 & 0
\end{array}\right)^{2}=1
$$

and the relation ${ }^{24}$

$$
\frac{1}{2} \int_{-1}^{1} d u e^{i u(z-y)}=\sum_{L}(2 L+1) j_{L}(z) j_{L}(y),
$$

to obtain

$$
\begin{equation*}
\frac{1}{\left(2 l_{0}+1\right)} \sum_{l, m, m_{0}}\left|\mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}(\vec{\kappa})\right|^{2}=\left(\pi 2^{n+n_{0}} n!n_{0}!\right)^{-1} \frac{1}{2} \int_{-1}^{1} d u\left|\int_{-\infty}^{\infty} d \xi e^{i 2^{1 / 2} \kappa d u\left(\xi+\xi_{e}\right)} H_{n}(\xi) H_{n_{0}}(\xi) e^{-\xi^{2}}\right|^{2} \tag{63}
\end{equation*}
$$

The integral on $\xi$ in Eq. (61) may be performed

$$
\int_{-\infty}^{\infty} d \xi e^{i 2^{1 / 2} \kappa d u\left(\xi+\xi_{e}\right)} e^{-\xi^{2}} H_{n}(\xi) H_{n_{0}}(\xi)=e^{i 2^{1 / 2} \kappa d u \xi} e e^{-\kappa^{2} d^{2} u^{2} / 2} 2^{\left(n_{g}+n_{l}\right) / 2} \sqrt{\pi} n_{l}!(-i \kappa d u)^{n_{g}-n_{l}} L_{n_{l}}^{\left(n_{g}-n_{l}\right)}\left(\kappa^{2} d^{2} u^{2}\right),
$$

where $n_{l}$ and $n_{g}$ are the lesser and greater of $n_{0}$ and $n$ and where $L_{n}^{(\alpha)}(x)$ is an associated Laguerre polynomial. ${ }^{22}$ Equation (58) then becomes

The interference term in the expression for the inelastic-scattering differential cross section may be reduced in a similar manner:

$$
\begin{align*}
\frac{1}{\left(2 l_{0}+1\right)} \sum_{l, m, m_{0}} \mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}\left(-\beta_{b} \overrightarrow{\mathrm{q}}\right) \mathcal{F}_{n, l, m ; n_{0}, l_{0}, m_{0}}^{*}\left(-\beta_{c} \overrightarrow{\mathrm{q}}\right)= & \int_{0}^{1} d u \cos \left(\sqrt{2} \xi_{e} y\right) e^{-y^{2}\left(\beta_{b}^{2}+\beta_{c}^{2}\right) / 2}\left(n_{l}!/ n_{g}!\right) \\
& \times\left(\beta_{b} \beta_{c} y^{2}\right)^{n_{g}-n_{l}} L_{n_{l}}^{\left(n_{g}-n_{l}\right)}\left(\beta_{b}^{2} y^{2}\right) L_{n_{l}}^{\left(n_{g}-n_{l}\right)}\left(\beta_{c}^{2} y^{2}\right) \approx 0, \tag{65}
\end{align*}
$$

where we have defined $y \equiv q u d$ and noted that the integral will vanish because of the rapidly oscillating cosine term.

If the molecule is initially in the lowest vibrational state, the integral in Eq. (64) is

$$
\begin{align*}
\frac{1}{\left(2 l_{0}+1\right)} \sum_{l, m, m_{0}}\left|\mathcal{F}_{n, l, m ; 0, l_{0} m_{0}}(\vec{\kappa})\right|^{2} & =(n!\kappa d)^{-1} \int_{0}^{k d} d x e^{-x^{2} x^{2 n}}  \tag{66}\\
& =\gamma\left(n+\frac{1}{2}, \kappa^{2} d^{2}\right) /(2 n!\kappa d),
\end{align*}
$$

where $\gamma(a, z)$ is the usual incomplete $\Gamma$ function. ${ }^{22}$ This expression is plotted in Fig. 1.

## IV. CALCULATION OF THE INELASTIC-SCATTERING CROSS SECTION

The differential cross section for excitation of the $n$th vibrational level of a diatomic molecule initially unpolarized and in the lowest vibrational state is given by Eqs. (18), (19), (38), (39), (65), and (67);

$$
\begin{align*}
\sigma_{n}(\theta, \varphi)=\left(k_{a}^{f} / k_{a}\right) & {\left[\left|\left(\mu_{r} / \mu_{a c}\right) \tilde{f}_{c}\left(\left(\mu_{a c} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}+\overrightarrow{\mathrm{q}},\left(\mu_{a c} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}\right)\right|^{2} \gamma\left(n+\frac{1}{2}, \beta_{c}^{2} q^{2} d^{2}\right) / 2 n!q_{d}\left|\beta_{c}\right|\right.} \\
& \left.+\left|\left(\mu_{r} / \mu_{a b}\right) \tilde{f}_{b}\left(\left(\mu_{a b} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}+\overrightarrow{\mathrm{q}},\left(\mu_{a b} / \mu_{r}\right) \overrightarrow{\mathrm{k}}_{r}\right)\right|^{2} \gamma\left(n+\frac{1}{2}, \beta_{b}^{2} q^{2} d^{2}\right) / 2 n!q d\left|\beta_{b}\right|\right], \tag{68}
\end{align*}
$$

and does not depend on the initial angular momentum quantum number $l_{0}$ (or on the distribution of $l_{0}$ values). The initial momentum of atom $a$ in the system in which the molecule $b c$ is at rest is $\overrightarrow{\mathrm{k}}_{a}$. The initial relative momentum $\vec{k}_{r}$ is given by

$$
\begin{equation*}
\overrightarrow{\mathrm{k}}_{r}=\left(m_{b}+m_{c}\right) \overrightarrow{\mathrm{k}}_{a} / M, \tag{69}
\end{equation*}
$$

the final relative momentum satisfies

$$
\begin{equation*}
\hbar^{2}\left(k_{r}^{2}-k_{r}^{\prime 2}\right) / 2 \mu_{r}=\epsilon_{n, l}-\epsilon_{n_{0}, l_{0}}=n \bar{\hbar} \omega_{0}, \tag{70}
\end{equation*}
$$

and the final momentum of atom $a$ in the $b c$ rest system is

$$
\overrightarrow{\mathrm{k}}_{a}^{f}=\overrightarrow{\mathrm{k}}_{r}^{\prime}+m_{a} \overrightarrow{\mathrm{k}}_{r} /\left(m_{b}+m_{c}\right) .
$$

We shall neglect the recoil of the molecule $b c$ here so the ratio $k_{\mathrm{a}}^{f} / k_{a}$ becomes

FIG. 1. Spherically averaged form factor for $0 \rightarrow n$ transitions $\gamma\left(n+\frac{1}{2}, \chi^{2}\right) / 2 n!\chi$. The parameter $\chi$ is the product of the oscillator length parameter $d$ and the magnitude of the momentum transfer $k$.

$$
\begin{equation*}
k_{a}^{f} / k_{a}=k_{r}^{\prime} / k_{r} \tag{71}
\end{equation*}
$$

In order to proceed further, we must calculate the free scattering amplitude $\tilde{f}_{i}\left(\overrightarrow{\mathrm{k}}_{2}, \overrightarrow{\mathrm{k}}_{1}\right)$ defined in Eq. (42). This is the Fourier transform of the product of the potential $V_{i}$ and the true wave function for scattering of atom $a$ by atom $i$ when the initial relative momentum is $\overrightarrow{\mathrm{k}}_{1}$. When $\left|\overrightarrow{\mathrm{k}}_{2}\right|^{2}$ $=\left|\overrightarrow{\mathrm{k}}_{1}\right|^{2}$, this is simply the scattering amplitude for elastic $a-i$ scattering and may be determined from scattering experiments. Here, we require these scattering amplitudes for values of $\left|\overrightarrow{\mathrm{k}}_{2}\right|^{2}$ not equal to $\left|\overrightarrow{\mathrm{k}}_{1}\right|^{2}$ as well. These "off-the-energyshell" T-matrix elements also appear in the integral equations of scattering theory ${ }^{20}$ where they are related to the scattering wave function within the range of the potential.
Although the wave function $\chi^{(i)} \overrightarrow{\mathrm{k}}_{1}(\vec{\rho})$ and hence the free scattering amplitudes may be calculated exactly once the two-body potentials $V_{i}(\rho)$ are specified, we shall not make this calculation here but characterize the free amplitude by

$$
\begin{align*}
\left|\tilde{f}_{i}\left(\overrightarrow{\mathrm{k}}_{2}, \overrightarrow{\mathrm{k}}_{1}\right)\right|^{2} & \approx\left|\hat{f}_{i}\left(\vec{k}_{2}, \vec{k}_{1}\right)\right|^{2} \\
& \equiv\left(1+k_{1}^{2} r_{i}^{2} e^{-\left|\overrightarrow{\mathrm{k}}_{2}-\overrightarrow{\mathrm{k}}_{1}\right|^{2} r_{i}^{2 / 4}}\right) \hat{\sigma}_{i} / 8 \pi \tag{72}
\end{align*}
$$

This function is the sum of a constant term and a peak in the forward direction ( $\overrightarrow{\mathrm{k}}_{2}=\overrightarrow{\mathrm{k}}_{1}$ ). The total elastic-scattering cross section in this approximation is
$\int_{0}^{2 \pi} d \varphi \int_{0}^{\pi} \sin \theta d \theta\left|\hat{f}_{i}\left(\overrightarrow{\mathrm{k}}_{2}, \overrightarrow{\mathrm{k}}_{1}\right)\right|_{k_{2}=k_{1}}^{2}=\hat{\sigma}_{i}\left(1-\frac{1}{2} e^{-k_{1}^{2} r_{i}^{2}}\right)$
with the constant part of $\left|\hat{f}_{i}\right|^{2}$ contributing $\frac{1}{2} \hat{\sigma}_{i}$ and the forward peak contributing $\frac{1}{2} \hat{\sigma}_{i}\left(1-e^{-k_{1}^{2} r_{i}^{2}}\right)$. The angular integration is facilitated by noting that

$$
\boldsymbol{q}^{2} \equiv\left|\overrightarrow{\mathrm{k}}_{2}-\overrightarrow{\mathrm{k}}_{1}\right|^{2}=k_{1}^{2}+k_{2}^{2}-2 k_{1} k_{2} \cos \theta
$$

and hence

$$
\begin{equation*}
\int_{0}^{2 \pi} d \varphi \int_{0}^{\pi} \sin \theta d \theta g\left(q^{2}\right)=2 \pi \int_{k_{1}-k_{2}}^{k_{1}+k_{2}} q d q g\left(q^{2}\right) / k_{1} k_{2} \tag{74}
\end{equation*}
$$

The approximation $\hat{f}_{i}$ is an attempt to characterize the scattering amplitude for a wide class of potentials for $k_{1} r_{i} \gg 1$, where $r_{i}$ is the range of the potential $V_{i}(\rho)$. In the Born approximation, for example, $\tilde{f}_{i}$ is given by
$\tilde{f}_{i}\left(\overrightarrow{\mathrm{k}}_{1}+\overrightarrow{\mathrm{q}}, \overrightarrow{\mathrm{k}}_{1}\right)_{\text {Born }}=-\left(2 \mu_{a_{i}} / \hbar^{2}\right) \int_{0}^{\infty} \rho^{2} d \rho V_{i}(\rho) \sin q \rho / q \rho$
and is clearly peaked about $q=0$ with a width of the order of $r_{i}^{-1}$.

When $k_{1} r_{i}$ is large, the exact amplitude for scattering by an infinitely repulsive sphere also exhibits a diffraction peak of width $r_{i}{ }^{25}$ for values of $\vec{q}$ both on and off the energy shell and satisfies the relationship between the total elastic-scattering cross section $\sigma_{i}$ and the forward-scattering amplitude

$$
\left|\widetilde{f}\left(\overrightarrow{\mathrm{k}}_{1}, \overrightarrow{\mathrm{k}}_{1}\right)\right|^{2}=\left(1+k_{1}^{2} r_{i}^{2}\right) \sigma_{i} / 8 \pi
$$

The inelastic-scattering differential cross section Eq. (68) is the sum of two similar terms

$$
\begin{equation*}
\sigma_{n}(\theta, \varphi)=\sigma_{n}^{(b)}(\theta, \varphi)+\sigma_{n}^{(c)}(\theta, \varphi), \tag{76}
\end{equation*}
$$

where

$$
\begin{align*}
\sigma_{n}^{(i)}(\theta, \varphi)= & \hat{\sigma}_{i}\left(k_{r}^{\prime} / k_{r}\right) \gamma\left(n+\frac{1}{2}, \beta_{i}^{2} q^{2} d^{2}\right) \\
& \times \frac{\left(\mu_{r} / \mu_{a_{i}}\right)^{2}+k_{r}^{2} r_{i}^{2} e^{-q^{2} r_{i}^{2} / 4}}{16 \pi n!q d \mid \beta_{i}} \tag{77}
\end{align*}
$$

and where we have used Eqs. (71) and (72). We may use Eq. (74) to integrate Eq. (77);

$$
\begin{align*}
\sigma_{n}^{(i)} \equiv & \int_{0}^{2 \pi} d \varphi \int_{0}^{\pi} \sin \theta d \theta \sigma_{n}^{(i)}(\theta, \varphi) \\
= & \hat{\sigma}_{i} \int_{u_{\bar{n}}}^{u_{n}^{+}} \chi d \chi\left(\frac{\gamma\left(n+\frac{1}{2}, \chi^{2}\right)}{2 n!\chi}\right)\left[\left(\frac{\mu_{r}}{\mu_{a_{i}} u_{0}^{+}}\right)^{2}+\eta_{i} e^{-\chi^{2} \eta_{i}}\right] \\
& \quad \text { for }\left(k_{r} d\right)^{2} \geqslant n \mu_{r} / \mu_{\tau}  \tag{78a}\\
= & 0 \text { otherwise } \tag{78b}
\end{align*}
$$

where

$$
\begin{equation*}
\eta_{i} \equiv\left(r_{i} / 2 \beta_{i} d\right)^{2} \tag{79}
\end{equation*}
$$

and

$$
\begin{align*}
u_{n}^{ \pm} & \equiv\left|\beta_{i}\right|\left(k_{r} \pm k_{r}^{\prime}\right) d \\
& =\left|\beta_{i}\right|\left\{k_{r} d_{ \pm}\left[\left(k_{r} d\right)^{2}-n \mu_{r} / \mu_{\tau}\right]^{1 / 2}\right\} \tag{80}
\end{align*}
$$

Since the range of the potential $r_{i}$ is of the same order of magnitude as the equilibrium oscillator spacing $\tau_{e}$ and $\xi_{e}^{2}=\tau_{e}^{2} / 2 d^{2}$ is very large, $\eta_{i}$ will be very large and will contribute to the integral (78a)
only for $\chi \ll 1$. We see from Fig. 1 that

$$
\gamma\left(n+\frac{1}{2}, \chi^{2}\right) / 2 n!\chi \approx \delta_{n, 6} \text { for } \chi \ll 1
$$

hence the diffraction peak will contribute only when $n=0$, and Eq. (78a) becomes

$$
\begin{align*}
\sigma_{n}^{(i)}= & \frac{1}{2} \hat{\sigma}_{i}\left[\delta_{n, 0}+\frac{1}{n!}\left(\frac{\mu_{r}}{\mu_{a_{i}} u_{0}^{+}}\right)^{2}\left[I_{n}\left(u_{n}^{+}\right)-I_{n}\left(u_{n}^{-}\right)\right]\right] \\
& \text {for }\left(k_{r} d\right)^{2} \geqslant n \mu_{r} / \mu_{\tau} \tag{81}
\end{align*}
$$

where

$$
\begin{equation*}
I_{n}(u)=\int_{0}^{u} d \chi \gamma\left(n+\frac{1}{2}, \chi^{2}\right)=u \gamma\left(n+\frac{1}{2}, u^{2}\right)-\gamma\left(n+1, u^{2}\right) \tag{82}
\end{equation*}
$$

The factor $\left(\mu_{r} / \mu_{a_{i}}\right)^{2}$ in Eq. (81) arises from the attempt to relate $f_{i}$ to the free particle scattering amplitudes $f_{i}$ in Eqs. (38) and (39) and always appears in the final expression for the cross section in the impulse approximation. ${ }^{21}$ This factor does not appear multiplying the Kronecker $\delta$ because we have taken the height of the diffraction peak to be proportional to $\left(\mu_{a_{i}} / \mu_{r}\right)^{2} k_{r}^{2}$.

Let us now consider the vibrational excitation of a stationary CO molecule by collision with a beam of oxygen atoms with velocity $V_{a}$. The ratio $\left(\mu_{r} /\right.$ $\mu_{a i}$ ) is given by

$$
\begin{equation*}
\mu_{r} / \mu_{a i}=\left(m_{b}+m_{c}\right)\left(m_{a}+m_{i}\right) / m_{i}\left(m_{a}+m_{b}+m_{c}\right) \tag{83}
\end{equation*}
$$

hence $\mu_{r} / \mu_{c 0}=\mu_{r} / \mu_{\tau}=1.4849, \mu_{r} / \mu_{00}=1.2727$, $\left|\beta_{0}\right|=0.42857$, and $\left|\beta_{c}\right|=0.57143$. Since $m_{a} V_{a}$ $=\hbar k_{a}$, we have

$$
\begin{equation*}
\left(k_{r} d\right)^{2}=\frac{\frac{1}{2} m_{a} V_{a}^{2}}{\hbar \omega_{0}}\left(\frac{\left(m_{b}+m_{c}\right)^{2} m_{a}}{\mu_{\tau} M^{2}}\right) \tag{84}
\end{equation*}
$$

where we have used Eqs. (33) and (49).
When we insert $\hbar \omega_{0}=0.26898 \mathrm{eV}^{13}$ we find

$$
k_{r} d=1.8743 E_{k}^{1 / 2}=0.53932 V_{a}
$$

where $E_{k}=\frac{1}{2} m_{0} V^{2}$ is the kinetic energy of the oxygen atom in electron volts and $V_{a}$ is the velocity in $\mathrm{km} / \mathrm{sec}$. The only remaining quantities required to calculate the inelastic-scattering cross section are $\hat{\sigma}_{0}$ and $\hat{\sigma}_{c}$.

The transition probability per collision is

$$
\begin{equation*}
P_{0 \rightarrow n}=\left(\sigma_{n}^{(0)}+\sigma_{0}^{(c)}\right) /\left(\sigma_{T}^{(0)}+\sigma_{T}^{(c)}\right) \tag{85}
\end{equation*}
$$

where

$$
\begin{equation*}
\sigma_{T}^{(i)}=\sum_{n} \sigma_{n}^{(i)} \tag{86}
\end{equation*}
$$

is the contribution to the total cross section from a particular atom of the diatomic molecule. The transition probability will be between the limits $P_{0 \rightarrow n}^{(0)}$ and $P_{0 \rightarrow n}^{(c)}$ depending on the value of the ratio

${ }^{\text {a }}$ The row labeled $T$ contains the ratio of the total cross section to $\hat{\sigma}$ in the $\sigma_{n} / \hat{\sigma}$ column.
$\hat{\sigma}_{0} / \hat{\sigma}_{c}$, where

$$
\begin{equation*}
P_{0 \rightarrow n}^{(i)} \equiv \sigma_{n}^{(i)} / \sigma_{T}^{(i)} \tag{87}
\end{equation*}
$$

The quantities $\sigma_{n}^{(i)} / \hat{\sigma}_{i}, \sigma_{r}^{(i)} / \hat{\sigma}_{i}$, and $P_{o \rightarrow n}^{(i)}$ do not depend upon $\hat{\sigma}_{i}$ and are listed in Table I for incident velocities in the $\mathrm{km} / \mathrm{sec}$ range. The bounds on $P_{0 \rightarrow n}\left(P_{0 \rightarrow n}^{(0)}\right.$ and $\left.P_{0 \rightarrow n}^{(c)}\right)$ are also plotted in Fig. 2 for transitions up to $n=4$.

The probability per collision of vibrational excitation of carbon monoxide by oxygen in a shock wave for temperatures between 1800 and $4000^{\circ} \mathrm{K}$ has been measured by Center ${ }^{28}$ and found to be of the order of $10^{-2}$. This agrees with our findings when we multiply our average probability per collision above threshold by the fraction of collisions
in an equilibrium gas of temperature $T$ for which the relative energy is above the threshold energy $E_{t}$. This factor is $^{27}$

$$
\begin{equation*}
e^{-x}(1+x) \tag{88}
\end{equation*}
$$

where $x=E_{t} / k T$ and lies between 0.48 and 0.82 for these temperatures.

## V. SUMMARY

We have found that the assumptions leading to the impulse approximation are justified for atom-diatomic-molecule collisions provided the interaction is dominated by short-range forces. In the impulse approximation, the expression for the inelastic-scattering amplitude factors into a

FIG. 2. Vibrational-excitation probabilities for collisions between carbon monox:1/ at rest in the lowest vibrational state and atomic c.aygen with velocity $V$. The transition probability $P_{0 \rightarrow n}$ lies within the shaded region depending on the ratio $\hat{\sigma}_{0} / \hat{\sigma}_{c}$. The boundaries of the shaded regions are $P_{0} \stackrel{(c)}{\rightarrow}$ and $P_{0} \xrightarrow{(0)}$.
bound-state form factor and an atom-atom scattering amplitude that must be evaluated off the energy shell. We have found a closed-form expression for the bound-state form factor for vibrational
excitations by using a closure approximation to evaluate the sums over final angular momentum quantum numbers. We find that the vibrational inelastic-scattering cross sections do not depend on the initial angular momentum quantum number $l_{0}$.

Vibrational-transition probabilities evaluated using a fairly rough estimate for the atom-atom scattering amplitudes are in qualitative agreement with experiment. An improved estimate of the atom-atom scattering amplitude may be obtained semiclassically, quantum mechanically, or from atom-atom cross-section experiments.

We have found that the impulse approximation provides a rigorous tool for the calculation of atom-diatomic-molecule inelastic-scattering cross sections. We suggest that the application of the impulse approximation to diatomic-diatom-ic-molecule and various polyatomic collisions be investigated.
