(Received 14 May 2019; published 15 July 2019)

We study the formation of band gap bound states induced by a non-Hermitian impurity embedded in a Hermitian system. We show that a pair of bound states emerges inside the band gap when a parity-time ( $\mathcal{PT}$ ) imaginary potential is added in strongly coupled bilayer lattices and the bound states become strongly localized when the system approaches the exceptional point. As a direct consequence of such  $\mathcal{PT}$  impurity-induced bound states, an impurity array can be constructed and protected by energy gap. The effective Hamiltonian of the impurity array is non-Hermitian Su-Schrieffer-Heeger type and hosts Dirac probability-preserving dynamics. We demonstrate the conclusion by numerical simulations for the quantum transport of wave packet in right-angle bends waveguide and  $Y$ -beam splitter. Our finding provides an alternative way to fabricate quantum device by non-Hermitian impurity.

### I. INTRODUCTION

Throughout physics, stable or equilibrium phenomena can be understood by bound state, ranging from quantum to classical objects. In quantum physics, a bound state is a localized state of a particle subject to a real valued potential, which may be the result of the presence of other particles. The concept of bound state is ubiquitous in numerous branches of physics, such as optics and condensed matter. In experiment, engineering bound state can be generated by artificial defects in photonic crystals and an array of defects, which are known as coupled-resonator optical waveguides providing almost lossless guiding, and bending of wave packet [1–11]. By introducing artificial defects, various photonic crystal devices can be realized for the applications in a wide variety of fields. Nowadays a complex potential is not forbidden since non-Hermitian quantum mechanics has emerged as a versatile platform for fabricating functional devices in a non-Hermitian regime. The main mechanism is based on the existence of imaginary potential, which has been investigated theoretically [12–30] and realized in experiment [31–40] as an ideal building block of non-Hermitian systems. A non-Hermitian term has a distinguishing feature that differs from a Hermitian one and can be exemplified by a simple two level system. An extra pseudo-Hermitian non-Hermitian term always shrinks the level spacing, while a nontrivial Hermitian perturbation always leads to the repulsion of the two levels. Presumably, midgap levels can be generated by adding non-Hermitian impurity on a Hermitian gapped system.

In this paper, we study the possibility of a quantum channel generated by an array of non-Hermitian defects. Based on the Bethe ansatz solution we show that a pair of bound states emerges inside the band gap when a parity-time ( $\mathcal{PT}$ ) imaginary potential is added in a strongly coupled bilayer. Such bound states are protected by energy gap, especially as the bound-state energy tends to zero when the system

approaches the exceptional point (EP). Consequently, an impurity array can be constructed in the midgap and provides a low-loss waveguide since other Hermitian degrees of freedom are adiabatically eliminated when we consider the dynamics in the impurity array. In addition, we show that the effective Hamiltonian of the impurity array is equivalent to a non-Hermitian Su-Schrieffer-Heeger (SSH) system and obeys chiral-time ( $\mathcal{CT}$ ) symmetry. This ensures quasiorthogonality of the midgap modes in the framework of Dirac inner product, and therefore the Dirac probability-preserving dynamics in the waveguide. Therefore, although the waveguide is engineered by non-Hermitian impurities, it acts as a conditional Hermitian device. We demonstrate the conclusion by numerical simulations for the quantum transport of wave packet in right-angle bends waveguide and  $Y$ -beam splitter. Our finding provides an alternative way to fabricate quantum device by non-Hermitian impurity.

This paper is organized as follows. In Sec. II, we present the main ideas of the non-Hermitian-impurity induced waveguide. In Sec. III, we provide a concrete example to illustrate our theory. Section IV demonstrates the dynamics of waveguide in the concrete system. Finally, our conclusion is given in Sec. V.

### II. FORMALISM

Consider a bilayer system [Fig. 1(a)], composed of two identical lattices but with opposite on-site energies. The inter-layer tunneling is non-Hermitian and sparse, which is referred to as non-Hermitian impurity. The Hamiltonian is given by

$$\begin{aligned}
 H &= H_0 + H_T, \\
 H_0 &= \sum_{(i,j)} \sum_{\sigma=\pm} (\kappa_{ij} a_{i,\sigma}^\dagger a_{j,\sigma} + \text{H.c.}) + \sum_j \sum_{\sigma=\pm} \sigma \Delta a_{j,\sigma}^\dagger a_{j,\sigma}, \\
 H_T &= i \sum_j T_j (a_{j,+}^\dagger a_{j,-} + \text{H.c.}),
 \end{aligned} \tag{1}$$

where  $\sigma$  corresponds to the + and – layers and  $\{iT_j\}$  is a set of imaginary intralayer hopping parameters. Figure 1(a)

\*songtc@nankai.edu.cn

FIG. 1. (a) Schematic illustration of a two-layer tight-binding lattice with non-Hermitian imaginary tunneling. (b) Band structures for  $H_0$  and  $H$ . In the absence of the interlayer tunneling, a gap in order of  $2\Delta$  opens. When a single tunneling  $iT_j$  switches on, two isolated energy levels can be achieved around the midgap.

is the schematic illustration of the model. We consider the region with  $\Delta \gg |\kappa_{ij}|$ , which ensures the energy gap of order  $\Delta$  between two (+/-) energy bands for the system  $H_0$ . In the following, we show that  $H_T$  may induce local states within the energy gap.

In the absence of  $H_T$ , the states of  $H_0$  are extended states spreading the probability over the two layers. In the limit case with  $|T_j| \sim \Delta \gg |\kappa_{ij}|$ , each non-Hermitian tunneling  $iT_j$  may induce two isolated energy levels around the midgap, which have the form  $\pm\sqrt{\Delta^2 - (T_j)^2}$ . It is responsible for the non-Hermiticity of the impurity, since a real tunneling cannot form the isolated levels within the energy gap, but beyond the two bands. Figure 1(b) is the band structure for  $H_0$  and  $H$ . We note that the eigenvalues of  $H$  are real or imaginary, i.e., the EPs only appear at zero energy. Considering the case with a single nonzero  $T_j$ , there are two isolated levels within the gap and such two bound states coalesce to a single state  $(1/\sqrt{2})(a_{j,-}^\dagger + ia_{j,+}^\dagger)|\text{vac}\rangle$  at the EP when  $\Delta = |T_j|$ . If there are many such nonzero tunneling  $T_j$  within the unbroken region and the corresponding bound states overlap with each other, sub-bands within the gap will form and a non-Hermitian-impurity induced waveguide is achieved for a array of impurity.

To demonstrate the main idea, we consider an example model, which consists of two infinite chains with a single non-Hermitian tunneling. The corresponding Hamiltonian has the form

$$H_{\text{chain}} = \sum_{j=-\infty}^{\infty} \sum_{\sigma=\pm} [(\kappa a_{j,\sigma}^\dagger a_{j+1,\sigma} + \text{H.c.}) + \sigma \Delta a_{j,\sigma}^\dagger a_{j,\sigma}] + iT(a_{0,+}^\dagger a_{0,-} + a_{0,-}^\dagger a_{0,+}), \quad (2)$$

where  $\sigma = +$  or  $-$  is the index that respectively labels the position in the top or bottom chains and  $j$  is the in-chain site index. Parameters  $\kappa$  and  $T$  of this model are intra- and interchain hopping strengths. The schematic illustration is shown in Fig. 2(a). Bethe ansatz method shows that there are two bound states around the center with the eigenvector (see Appendix 1)

$$|\psi_B\rangle = C \sum_{j=-\infty}^{\infty} (e^{i\pi j} e^{-\beta^+ |j|} a_{j,+}^\dagger) |\text{vac}\rangle - C \frac{2\kappa}{iT} \sinh \beta^+ \sum_{j=-\infty}^{\infty} (e^{-\beta^- |j|} a_{j,-}^\dagger) |\text{vac}\rangle. \quad (3)$$

FIG. 2. (a) Schematic illustration of a bichain lattice with opposite chemical potentials  $\pm\Delta$  and a single non-Hermitian tunneling  $iT$ . The intra- and interlayer hopping strengths are  $\kappa$  and  $iT$ , respectively. (b) Profile of one of the two bound states for single imaginary tunneling  $iT$ . The ordinates of blue (solid) and red (dash) lines are real and imaginary numbers, which represent the wave function of the top and bottom chains, respectively. The parameters are  $\Delta = 5$ ,  $\kappa = 1$ , and  $T = 4$ . Panels (c1) and (c2) are profiles of two of the four bound states for double imaginary tunneling  $iT$ . The parameters are  $\Delta = 5$ ,  $\kappa = 1$ , and  $T = 4$ . Panels (d1)–(d3) are profiles of three of the ten bound states induced by multi(five) impurities with parameters  $\Delta = 5$ ,  $\kappa = 1$ , and  $T = 4$ . The results are obtained by numerical diagonalization and the wave functions are Dirac normalized.

Here  $C$  is the normalization coefficient, which is determined in the context of Dirac or biorthogonal inner products. Profile of the bound state is shown in Fig. 2(b). The corresponding eigenenergy is

$$E_B = -2\kappa \cosh \beta^+ + \Delta = 2\kappa \cosh \beta^- - \Delta, \quad (4)$$

where  $\beta^\pm$  are positive real numbers and fulfill the equations

$$\cosh \beta^- + \cosh \beta^+ = \Delta/\kappa, \quad (5)$$

$$\sinh \beta^+ \sinh \beta^- = T^2/(2\kappa)^2.$$

We note that two bound states coalesce to a single one

$$|\psi_B^{\text{EP}}\rangle = C \sum_{j=-\infty}^{\infty} (e^{i\pi j} e^{-\beta |j|} a_{j,+}^\dagger + i e^{-\beta |j|} a_{j,-}^\dagger) |\text{vac}\rangle \quad (6)$$

at EP with  $\beta = \ln[\Delta/(2\kappa) + \sqrt{\Delta^2/(4\kappa^2) - 1}]$  and  $T = T_c = \sqrt{\Delta^2 - (2\kappa)^2}$ . When  $T > T_c$ , the bound-state energy becomes an imaginary number. This exact solution indicates that stable bound states can be formed by the non-Hermitian impurity. In the case of multi-impurities, the above exact solution is

FIG. 3. (a) Schematic illustration of a bilayer square lattice model with  $\kappa$  (gray line) and  $\Delta$  (black line) are intra- and interlayer hopping strengths; the non-Hermitian imaginary potentials  $\pm i\gamma$  are indicated by the blue ( $i\gamma$ ) and yellow ( $-i\gamma$ ) dots, and the white dots indicate zero on-site potentials. (b) The waveguide path [red dash lines in (a)] forms a non-Hermitian ladder model.

still applicable when the distance between two neighboring impurities is sufficiently large. Nevertheless, the overlap of the wave functions occur and extended states form within the region of the impurity array. Figures 2(c) and 2(d) are plots of several typical bound states for two and five imaginary impurities. For  $n$  impurities, the system supports  $2n$  bound states confined to the region of the array. Consequently, the midgap sub-bands may form for large  $n$ .

This result has many implications. (i) Similar to the Hermitian regime, imaginary impurities can induce local bound states with real energies. (ii) In contrast to a Hermitian impurity, energy levels of imaginary impurity can be protected by band gap and coalesce at EP. (iii) Deliberately designed impurity array can take the role of waveguide. It allows a variety of non-Hermitian models with various geometries and a wide range of parameters to be candidates of waveguides. In the next section, we will show its application in an example.

### III. BILAYER SQUARE LATTICE

The bound states induced by non-Hermitian impurities can be employed to construct sub-bands in the energy gap, which constitute the channel for specific transport of particle, as a waveguide in a Hermitian system. In the Hermitian realm, the waveguides of most kinds of discrete systems have been well studied. It is usually done by destroying the translational symmetry. In the present work, our strategy is doing the same thing but by adding non-Hermitian terms. In the following, we will present an example that implements a 1D waveguide over a square lattice along any desired path.

We consider a bilayer square lattice model which is shown in Fig. 3(a). The Hamiltonian can be written as the Hermitian part  $H_0$  and non-Hermitian part  $H_T$ ,

$$H = H_0 + H_T. \quad (7)$$

The corresponding Hermitian Hamiltonian has the form

$$H_0 = H_1 + H_2 + H_{12},$$

$$H_\lambda = \kappa \sum_{j,l} \alpha_{j,l,\lambda}^\dagger (\alpha_{j+1,l,\lambda} + \alpha_{j,l+1,\lambda}) + \text{H.c.}, \quad (8)$$

$$H_{12} = \Delta \sum_{j,l} \alpha_{j,l,1}^\dagger \alpha_{j,l,2} + \text{H.c.},$$

where  $\lambda = 1$  or  $2$  is the index that respectively labels the position in the top or bottom layers and  $(j, l)$  is the in-plane site index. Parameters  $\kappa$  and  $\Delta$  of this model are intra- and interlayer hopping strengths. And the distribution of imaginary potentials is given as the form

$$H_T = i \sum_{\lambda=1}^2 \sum_{j,l} (-1)^{\lambda+j+l} \gamma_{jl} \alpha_{j,l,\lambda}^\dagger \alpha_{j,l,\lambda}. \quad (9)$$

By taking the linear transformations

$$a_{j,l,\pm}^\dagger = \frac{1}{\sqrt{2}} (\alpha_{j,l,1}^\dagger \pm \alpha_{j,l,2}^\dagger), \quad (10)$$

the Hamiltonian Eq. (8) can be written as

$$H_0 = \kappa \sum_{j,l} \sum_{\sigma=\pm} a_{j,l,\sigma}^\dagger (a_{j+1,l,\sigma} + a_{j,l+1,\sigma}) + \text{H.c.}$$

$$+ \Delta \sum_{j,l} \sum_{\sigma=\pm} \sigma a_{j,l,\sigma}^\dagger a_{j,l,\sigma}. \quad (11)$$

We note that the bond (antibond) state of a rung can only be transited to the bond (antibond) state next to it with hopping strength  $\kappa$ . Therefore, it can be decomposed into two independent single layer square lattices with on-site potentials  $\Delta$  and  $-\Delta$ , respectively.

Accordingly, the non-Hermitian term reads

$$H_T = i \sum_{j,l} (-1)^{j+l+1} \gamma_{j,l} (a_{j,l,+}^\dagger a_{j,l,-} + \text{H.c.}), \quad (12)$$

which takes the role of interlayer imaginary tunneling. Obviously, the present model is a concrete example of the system depicted in Eq. (1). The obtained result is applicable to a wide kind of systems.

### IV. DYNAMICS IN WAVEGUIDE

Before proceeding, we present a general non-Hermitian model which exhibits Dirac-probability preserving dynamics. Considering a chiral symmetric system, the Hamiltonian can be written in the block off-diagonal form [41]

$$H = \begin{pmatrix} 0 & D \\ D^\dagger & 0 \end{pmatrix}, \quad (13)$$

where  $D$  as an arbitrary  $N \times N$  matrix. The basis in  $H$  can be a complete set of site states for a bipartite lattice. Based on  $H$  as the original Hermitian Hamiltonian, a non-Hermitian Hamiltonian  $\mathcal{H}$  is generated as the form

$$\mathcal{H} = H + i\gamma \sigma_z \otimes I_N, \quad (14)$$

where  $\sigma_z$  is the Pauli matrix and  $I_N$  denotes the  $N \times N$  identity matrix. The chiral symmetry of  $H$  ensures its eigenvalues and eigenvectors have the following properties. (i) The eigenvalues are always in pairs, i.e., the spectrum has the form  $\{\epsilon_n, \epsilon_{-n}\}$  with  $\epsilon_{-n} = -\epsilon_n$ . (ii) The corresponding eigenvector  $\{|\phi_n\rangle, |\phi_{-n}\rangle\}$  obeys

$$|\phi_n\rangle = (\sigma_z \otimes I_N) |\phi_{-n}\rangle. \quad (15)$$

It turns out that (see Appendix 2) the spectrum of  $\mathcal{H}$  has the form  $\{\epsilon_n, \epsilon_{-n}\}$  with

$$\epsilon_{\pm n} = \pm (\epsilon_n^2 - \gamma^2)^{1/2} \quad (16)$$

and the eigenvector of  $|\varphi_{\pm n}\rangle$  can be mapped directly from  $|\phi_{\pm n}\rangle$

$$|\varphi_{\pm n}\rangle = M_{\pm n}|\phi_{\pm n}\rangle \quad (17)$$

with the mapping matrix

$$M_{\pm n} = \begin{pmatrix} a_{\pm n}I_N & 0 \\ 0 & I_N \end{pmatrix}, \quad (18)$$

where  $a_{\pm n} = [\epsilon_{\pm n} + i\gamma]/\epsilon_{\pm n}$  is a complex number with unit modulus,  $|a_{\pm n}| = 1$ , for real  $\epsilon_{\pm n}$ .

Obviously,  $M_{\pm n}$  is a unitary matrix when the spectrum is fully real. Remarkably, it can be proved that eigenvector set  $\{|\varphi_{\pm n}\rangle\}$  obeys a quasiothonormal relation under the Dirac inner product, i.e.,

$$\langle \varphi_m | \varphi_n \rangle = \delta_{mn}, \quad (19)$$

for  $mn > 0$  and  $\epsilon_m \epsilon_n \neq 0$ . It indicates that the non-Hermitian system acts as a Hermitian one when only one of the subspaces with positive or negative spectrum is concerned. A direct conclusion is that the evolved state in one of the subspace of  $\mathcal{H}$  maintains the preservation of Dirac probability, exhibiting the Hermitian dynamic behavior.

Based on the above analysis, the bilayer system is a candidate for waveguide allowing quantum transport with probability preserving. We take the waveguide array by a collection of sites  $\{(j, l)\}$  and setting  $\gamma_{j,l} = \gamma$ , but zero for the rest of sites. In this paper, the set of sites  $\{(j, l)\}$  is selected under the rule: it forms a non-Hermitian ladder system, described by the Hamiltonian

$$H_{\text{ladd}} = \kappa \sum_{\lambda=1,2} \sum_{n=1}^N \alpha_{n,\lambda}^\dagger \alpha_{n+1,\lambda} + \Delta \sum_{n=1}^N \alpha_{n,1}^\dagger \alpha_{n,2} + \text{H.c.} \\ + \sum_{n=1}^N (-1)^n i\gamma (\alpha_{n,1}^\dagger \alpha_{n,1} - \alpha_{n,2}^\dagger \alpha_{n,2}). \quad (20)$$

The scheme is schematically illustrated in Fig. 3(b). There are numerous configurations for the path to connect any two distant locations. When the parameters are in the range  $\gamma \sim \Delta \gg |\kappa|$ , the subsystem  $H_{\text{ladd}}$  decouples from the bilayer system. The dynamics in the waveguide array is governed by the Hamiltonian  $H_{\text{ladd}}$ . In certain parameter regions,  $H_{\text{ladd}}$  possesses a fully real spectrum and obeys the Hermitian dynamics since it has the form of Eq. (14).

The system  $H_{\text{ladd}}$  can be regarded as an extended non-Hermitian SSH chain with long-range hopping term (see Appendix 3). It turns out that such a model shares the same dynamic behaviors with the simplest non-Hermitian SSH chain within a certain parameter region (strong dimerization limit), which has been studied in the previous works [42–44]. It is expected that the dynamics of a non-Hermitian SSH chain emerges in the bilayer square lattice with preengineered imaginary impurities.

To see waveguide dynamics in the bilayer square lattice system, we perform the numerical simulations. The initial state is taken as the bilayer Gaussian wave packet, which has the form

$$|\psi(0)\rangle = \Omega^{-1/2} \sum_{\lambda=1,2} \sum_{n=1}^N e^{-\alpha^2(n-N_c)^2/2} e^{ik_c n} \alpha_{n,\lambda}^\dagger |\text{vac}\rangle, \quad (21)$$

where  $n$  is the site index along the waveguide array,  $N_c$  is the center of the Gaussian wave packet,  $k_c$  is the central momentum, and  $\Omega = 2\sqrt{\pi}/\alpha$  is the Dirac normalization factor. According to previous work [42–44], the wave packet should propagate along the array without spreading approximately, if the sub-bands are sufficiently separated from the bilayer bands. The evolved state has the form

$$|\psi(t)\rangle = e^{-iHt} |\psi(0)\rangle, \quad (22)$$

which can be computed by exact diagonalization.

The probability distribution at position  $(i, j)$  at time  $t$  is defined by the sum of the Dirac probabilities of the top and bottom layers

$$p(i, j, t) = \sum_{\lambda=1,2} |\langle i, j, \lambda | \psi(t) \rangle|^2, \quad (23)$$

where  $|i, j, \lambda\rangle$  denotes the position state. To demonstrate the efficiency of the waveguide, we define the function

$$P(i, j) = \frac{p(i, j, t)_{\text{max}}}{[\sum_t p(i, j, t)]_{\text{max}}} \sum_t p(i, j, t) \quad (24)$$

to record the trace of the wave packet. The simulation is performed for the systems far from EP, i.e., the positive and negative waveguide bands are well separated, and two kinds of waveguide configurations: (i) a single path waveguide with two right-angle bends and (ii) a beam splitter with two right-angle bends. Their schematics are shown in Fig. 4(a) and Fig. 5(a). The initial state is a Gaussian wave packet with central momentum  $k_c = -\pi/2$ . Since it only relates to a single sub-band in the large gap limit, it is expected that the time evolution exhibits a probability preserving behavior approximately. For case (i), the numerical simulation results indicate that the wave packet propagates along the designed waveguide array path as expected. For (ii), it shows that the wave packet splits into two parts after passing through the joint. In both cases, the wave packet is confined within the defects well and transmitted efficiently around the corners. These numerical results demonstrate and verify our theory for quantum transport in a non-Hermitian impurity array.

## V. CONCLUSION AND DISCUSSION

In summary, we have studied the formation of band gap bound states induced by a non-Hermitian impurity embedded in a Hermitian system. We have shown that a pair of bound states emerges inside the band gap when a  $\mathcal{PT}$  imaginary potential is added in a strongly coupled bilayer and the bound states become strongly localized when the system approaches the exceptional point. Inspired by this, we construct an impurity array which can be described by a non-Hermitian SSH type effective Hamiltonian which possesses  $\mathcal{CT}$  symmetry. We establish a theory for a non-Hermitian impurity-induced waveguide, which paves the way for the non-Hermitian device design. As a supplementary material (Appendix 2) for our theory, we first provide a rigorous proof for the features of a  $\mathcal{CT}$ -symmetric system, including the reality spectrum and quasiothogonality of the Dirac inner product. We would like to point out that such two conclusions are independent of other requirements for the original Hermitian system, such

FIG. 4. (a) Schematic illustration of the waveguide path, which is obtained by taking the nonzero non-Hermitian imaginary potentials  $\pm i\gamma$  along the path. (b)–(e) Numerical simulations of the dynamics in waveguide. The initial state is a bilayer Gaussian wave packet. Probability distribution at  $t = 0$ ,  $t = T_i/2$ , and  $t = T_i$  are shown in (b), (c), and (d), respectively. (e) The trace of the wave packet. Parameters for the system are  $t = 1$ ,  $\Delta = 15$ , and  $\gamma = 11$ ; the size of the system is  $100 \times 60 \times 2$ . Parameters for the initial state Eq. (21) are  $\alpha = 0.4$ ,  $N_c = 10$ , and  $k_c = -\pi/2$ . The total duration of the simulation is  $T_i = 42J^{-1}$ , where  $J$  is the scale of the Hamiltonian and we take  $J = 1$ .

as translational symmetry. Thus a variety of non-Hermitian models with various geometries is allowed. The numerical simulations for the quantum transport of the wave packet in right-angle bends waveguide and Y-beam splitter have demonstrated this point.

#### APPENDIX

In this Appendix we present the Bethe ansatz solution for the Hamiltonian from Eq. (2) and properties of the non-Hermitian ladder system.

#### 1. Bound states induced by non-Hermitian impurity

For a single-tunneling non-Hermitian Hamiltonian (2), the bound-state Bethe ansatz wave function has the form

$$|\psi_B\rangle = \sum_{\sigma=\pm} \sum_{j=-\infty}^{\infty} C^{\sigma} (-\sigma)^{|j|} e^{-\beta^{\sigma}|j|} a_{j,\sigma}^{\dagger} |\text{vac}\rangle, \quad (\text{A1})$$

where  $\beta^{\sigma}$  is a positive real number, indicating the strength of localization around the non-Hermitian tunneling  $iT$ . The Schrödinger equation  $H_{\text{chain}}|\psi_B\rangle = E_B|\psi_B\rangle$  with bound-state energy  $E_B$  gives

$$\begin{aligned} E_B &= -2\kappa \cosh \beta^+ + \Delta \\ &= 2\kappa \cosh \beta^- - \Delta, \end{aligned} \quad (\text{A2})$$

FIG. 5. (a) Schematic illustration of the beam splitter waveguide. In order to get high transmission rate, we take  $\kappa \rightarrow \kappa/\sqrt{2}$  for the hopping (labeled by green arrows) connecting the joint. (b)–(e) Numerical simulations of the dynamics in waveguide. The initial state is a bilayer Gaussian wave packet. Probability distribution at  $t = 0$ ,  $t = T_i/2$ , and  $t = T_i$  are shown in (b), (c), and (d), respectively. (e) The trace of the wave packet. Parameters for the system are  $t = 1$ ,  $\Delta = 15$ , and  $\gamma = 11$ ; the size of the system is  $100 \times 60 \times 2$ . Parameters for the initial state Eq. (21) are  $\alpha = 0.4$ ,  $N_c = 10$ , and  $k_c = -\pi/2$ . The total duration of the simulation is  $T_i = 32J^{-1}$ , where  $J$  is the scale of the Hamiltonian and we take  $J = 1$ .

at  $|j| \geq 1$ , and

$$\begin{aligned} (\Delta - 2e^{-\beta^+} \kappa - E_B)C^+ + iT C^- &= 0, \\ iT C^+ + (-\Delta + 2e^{-\beta^-} \kappa - E_B)C^- &= 0, \end{aligned} \quad (\text{A3})$$

at  $j = 0$ . The existence of a bound-state solution requires

$$\begin{vmatrix} (\Delta - 2e^{-\beta^+} \kappa - E_B) & iT \\ iT & (-\Delta + 2e^{-\beta^-} \kappa - E_B) \end{vmatrix} = 0. \quad (\text{A4})$$

Then evanescent coefficient  $\beta^\sigma$  can be determined by

$$\begin{aligned} \cosh \beta^- + \cosh \beta^+ &= \Delta/\kappa, \\ \sinh \beta^+ \sinh \beta^- &= T^2/(2\kappa)^2, \end{aligned} \quad (\text{A5})$$

and Eq. (A3) leads to

$$C^\sigma = \frac{2\sigma\kappa}{iT} \sinh \beta^{-\sigma} C^{-\sigma}. \quad (\text{A6})$$

Then the wave function can be written as

$$\begin{aligned} |\psi_B\rangle &= \sum_{j=-\infty}^{\infty} (e^{i\pi j} e^{-\beta^+ |j|} a_{j,+}^\dagger) |\text{vac}\rangle \\ &\quad - \frac{2\kappa}{iT} \sinh \beta^+ \sum_{j=-\infty}^{\infty} (e^{-\beta^- |j|} a_{j,-}^\dagger) |\text{vac}\rangle, \end{aligned} \quad (\text{A7})$$

where the normalization coefficient is neglected since it should be valued in the frameworks of Dirac or biorthonormal inner product in practice. We note that Eq. (A5) is symmetric under the operation  $\beta^+ \leftrightarrow \beta^-$ . Thus, if  $(\beta^+, \beta^-) = (x, y)$  is a solution with the eigenvalue  $E_B$ , then  $(\beta^+, \beta^-) = (y, x)$  corresponds to another solution with eigenvalue  $-E_B$ . Accordingly, when we take  $T = T_c = \sqrt{\Delta^2 - (2\kappa)^2}$ , we have  $\beta_c = \beta^+ = \beta^-$  with

$$\beta_c = \ln[\Delta/(2\kappa) + \sqrt{\Delta^2/(4\kappa^2) - 1}] \quad (\text{A8})$$

and two bound states coalesce to a single state

$$|\psi_B^{\text{EP}}\rangle = \sum_{j=-\infty}^{\infty} (e^{i\pi j} e^{-\beta_c |j|} a_{j,+}^\dagger + i e^{-\beta_c |j|} a_{j,-}^\dagger) |\text{vac}\rangle, \quad (\text{A9})$$

with the eigenenergy  $E_B^{\text{EP}} = 0$ , indicating the occurrence of EP. We note that  $|\psi_B^{\text{EP}}\rangle$  has the identical Dirac probability distributions on the two chains.

In strong localization limit with  $e^{2\beta^\sigma} \gg 1$ , we have the approximate solutions

$$\begin{aligned} \begin{pmatrix} \beta^- \\ \beta^+ \end{pmatrix} &= \begin{pmatrix} \ln(\Delta/\kappa + \sqrt{\Delta^2 - T^2}/\kappa) \\ \ln(\Delta/\kappa - \sqrt{\Delta^2 - T^2}/\kappa) \end{pmatrix} \\ &\text{or} \begin{pmatrix} \ln(\Delta/\kappa - \sqrt{\Delta^2 - T^2}/\kappa) \\ \ln(\Delta/\kappa + \sqrt{\Delta^2 - T^2}/\kappa) \end{pmatrix}, \end{aligned} \quad (\text{A10})$$

which are still in agreement with the symmetry of Eq. (A5).

## 2. Dirac probability preservation

Consider a Hermitian Hamiltonian with chiral symmetry,

$$H = \begin{pmatrix} 0 & D \\ D^\dagger & 0 \end{pmatrix}, \quad (\text{A11})$$

where  $D$  is an arbitrary  $N \times N$  matrix. The Schrödinger equation is

$$H|\phi_{\pm n}\rangle = \varepsilon_{\pm n}|\phi_{\pm n}\rangle \quad (\text{A12})$$

and obeys

$$\varepsilon_{-n} = -\varepsilon_n, \quad |\phi_n\rangle = (\sigma_z \otimes I_N)|\phi_{-n}\rangle, \quad (\text{A13})$$

due to the chiral symmetry

$$\{\sigma_z \otimes I_N, H\} = 0. \quad (\text{A14})$$

A non-Hermitian Hamiltonian  $\mathcal{H}$  can be generated as the form

$$\mathcal{H} = H + i\gamma\sigma_z \otimes I_N, \quad (\text{A15})$$

where  $\sigma_z$  is the Pauli matrix and  $I_N$  denotes the  $N \times N$  identity matrix. We note that a non-Hermitian term breaks the chiral symmetry, but  $\mathcal{H}$  has  $\mathcal{CT}$  symmetry. The corresponding Schrödinger equation is

$$\mathcal{H}|\varphi_{\pm n}\rangle = \varepsilon_{\pm n}|\varphi_{\pm n}\rangle \quad (\text{A16})$$

and obeys

$$\varepsilon_{\pm n} = \pm(\varepsilon_n^2 - \gamma^2)^{1/2}, \quad |\varphi_{\pm n}\rangle = M_{\pm n}|\phi_{\pm n}\rangle, \quad (\text{A17})$$

with the mapping matrix

$$M_{\pm n} = \begin{pmatrix} a_{\pm n} I_N & 0 \\ 0 & I_N \end{pmatrix}, \quad (\text{A18})$$

where  $a_{\pm n} = [\varepsilon_{\pm n} + i\gamma]/\varepsilon_{\pm n}$  fulfills  $|a_{\pm n}| = 1$  for real  $\varepsilon_{\pm n}$  and is purely imaginary for imaginary  $\varepsilon_{\pm n}$ . For real  $\varepsilon_{\pm n}$ , the factor  $a_{\pm n}$  can be written in the form of  $a_{\pm n} = e^{i\theta_n}$ , with  $\theta_n = \arctan(\gamma/\varepsilon_{\pm n})$ . This can be shown as the following.

Actually, from

$$HM_{\pm n} = \begin{pmatrix} I_N & 0 \\ 0 & a_{\pm n} I_N \end{pmatrix} H, \quad (\text{A19})$$

we have  $H|\varphi_{\pm n}\rangle = (HM_{\pm n})|\phi_{\pm n}\rangle$ , and

$$\begin{aligned} H|\varphi_{\pm n}\rangle &= \varepsilon_{\pm n} \begin{pmatrix} I_N & 0 \\ 0 & a_{\pm n} I_N \end{pmatrix} |\phi_{\pm n}\rangle \\ &= \varepsilon_{\pm n} \begin{pmatrix} (a_{\pm n})^{-1} I_N & 0 \\ 0 & a_{\pm n} I_N \end{pmatrix} |\varphi_{\pm n}\rangle. \end{aligned} \quad (\text{A20})$$

Therefore, from

$$\mathcal{H}|\varphi_{\pm n}\rangle = (H + i\gamma\sigma_z \otimes I_N)|\varphi_{\pm n}\rangle \quad (\text{A21})$$

and  $a_{\pm n} = (\varepsilon_{\pm n} + i\gamma)/\varepsilon_{\pm n}$ ,  $\varepsilon_{\pm n} = \pm(\varepsilon_n^2 - \gamma^2)^{1/2}$ , we have  $\varepsilon_{\pm n}(a_{\pm n})^{-1} + i\gamma = \varepsilon_{\pm n}a_{\pm n} - i\gamma = \varepsilon_{\pm n}$ , which leads to

$$\mathcal{H}|\varphi_{\pm n}\rangle = \varepsilon_{\pm n}|\varphi_{\pm n}\rangle. \quad (\text{A22})$$

The mapping relation between vectors  $|\phi_n\rangle$  and  $|\varphi_n\rangle$  can result in many interesting and useful applications. In general, set  $\{|\phi_n\rangle\}$  obeys an orthogonal relation in the framework of the Dirac inner product, while set  $\{|\varphi_n\rangle\}$  does not due to the non-Hermiticity of  $\mathcal{H}$ . We will show that  $\{|\varphi_n\rangle\}$  still obeys a Dirac orthogonal relation within one of the subspace ( $n > 0$  or  $n < 0$ ).

We start with the eigenvector of Hermitian Hamiltonian  $H$ , which has the form

$$|\phi_n\rangle = \begin{pmatrix} A_n \\ B_n \end{pmatrix}, \quad (\text{A23})$$

where  $A_n$  and  $B_n$  are two  $N \times 1$  vectors, representing the wave function of sublattices  $A$  and  $B$ .  $\{|\phi_n\rangle\}$  fulfills the orthogonal normalization condition

$$\langle \phi_m | \phi_n \rangle = A_m^\dagger A_n + B_m^\dagger B_n = \delta_{mn}. \quad (\text{A24})$$

The Schrödinger equation of  $|\phi_n\rangle$  has the form

$$\begin{pmatrix} 0 & D \\ D^\dagger & 0 \end{pmatrix} \begin{pmatrix} A_n \\ B_n \end{pmatrix} = \varepsilon_n \begin{pmatrix} A_n \\ B_n \end{pmatrix} \quad (\text{A25})$$

or explicitly

$$\begin{aligned} DB_n &= \varepsilon_n A_n, \\ D^\dagger A_n &= \varepsilon_n B_n. \end{aligned} \quad (\text{A26})$$

Multiplying by  $A_m^\dagger$  or  $B_m^\dagger$ , respectively, we have

$$\begin{aligned} A_m^\dagger DB_n &= \varepsilon_n A_m^\dagger A_n, \\ B_m^\dagger D^\dagger A_n &= \varepsilon_n B_m^\dagger B_n. \end{aligned} \quad (\text{A27})$$

Considering the conjugation of the above Schrödinger equation (A26)

$$\begin{aligned} B_m^\dagger D^\dagger &= \varepsilon_m A_m^\dagger, \\ A_m^\dagger D &= \varepsilon_m B_m^\dagger, \end{aligned} \quad (\text{A28})$$

Eq. (A27) together with Eq. (A28) gives

$$\begin{aligned} \varepsilon_m B_m^\dagger B_n &= \varepsilon_n A_m^\dagger A_n, \\ \varepsilon_m A_m^\dagger A_n &= \varepsilon_n B_m^\dagger B_n, \end{aligned} \quad (\text{A29})$$

and consequently leads to

$$(\varepsilon_n + \varepsilon_m)(A_m^\dagger A_n - B_m^\dagger B_n) = 0. \quad (\text{A30})$$

In the case of  $mn > 0$  and  $\varepsilon_n \varepsilon_m \neq 0$ , we have

$$A_m^\dagger A_n - B_m^\dagger B_n = 0. \quad (\text{A31})$$

Together with the orthogonal normalization condition Eq. (A24), we obtain

$$A_m^\dagger A_n = B_m^\dagger B_n = \frac{1}{2} \delta_{mn}, \quad (\text{A32})$$

which means that eigenvector  $|\phi_n\rangle$  has the same Dirac probability in sublattices  $A$  and  $B$ .

This factor leads to an important conclusion for vector  $\{|\phi_n\rangle\}$ : different eigenstates in one of the subspace ( $mn > 0$ ) of  $\mathcal{H}$  are still orthogonal. In fact, the mapping matrix gives

$$\begin{aligned} \langle \varphi_m | \varphi_n \rangle &= \langle \phi_m | M_m^\dagger M_n | \phi_n \rangle \\ &= a_m^* a_n A_m^\dagger A_n + B_m^\dagger B_n \\ &= \frac{1}{2} (a_m^* a_n + 1) \delta_{mn}. \end{aligned} \quad (\text{A33})$$

In addition, for full real spectrum we have

$$\langle \varphi_m | \varphi_n \rangle = \delta_{mn}, \quad (\text{A34})$$

since  $M_n$  is unitary, i.e.,  $|a_n| = |e^{i\theta_n}| = 1$ .

As an application, we will show that for any initial state in one of the subspaces ( $n > 0$  or  $n < 0$ ) of the non-Hermitian system  $\mathcal{H}$ , the time evolution preserves the Dirac probability. Considering an initial state in one of the subspaces with the

FIG. 6. Spectra of (a) ladder model and (b) SSH model with the core matrix Eq. (A39) and Eq. (A40) for different  $\gamma$ . The Parameters are  $\kappa = 1$ ,  $\Delta = 5$ , and  $\gamma = 0, 2.5, 3$ .

form  $|\psi(t=0)\rangle = \sum_{n=1}^N C_n |\phi_n\rangle$  with  $\sum_{n=1}^N C_n^* C_n = 1$ , the evolved state can be written as

$$|\psi(t)\rangle = \sum_{n=1}^N C_n \exp(-i\varepsilon_n t) |\phi_n\rangle. \quad (\text{A35})$$

In the condition of a full real spectrum, the Dirac probability is

$$\begin{aligned} P(t) &= \langle \psi(t) | \psi(t) \rangle \\ &= \sum_{m,n=1}^N C_m^* C_n \exp[i(\varepsilon_m - \varepsilon_n)t] \langle \varphi_m | \varphi_n \rangle \\ &= 1, \end{aligned} \quad (\text{A36})$$

which maintains the preservation of the Dirac probability, exhibiting the Hermitian dynamic behavior.

### 3. Non-Hermitian ladder and SSH models

In the condition of  $\Delta \gg \kappa$  (strong dimerization limit), the non-Hermitian ladder described by the Hamiltonian in Eq. (20)

$$\begin{aligned} H_{\text{Ladd}} &= \kappa \sum_{\lambda=1,2} \sum_{j=1}^N \alpha_{j,\lambda}^\dagger \alpha_{j+1,\lambda} + \Delta \sum_{j=1}^N \alpha_{j,1}^\dagger \alpha_{j,2} + \text{H.c.} \\ &+ \sum_j (-1)^n i\gamma (\alpha_{j,1}^\dagger \alpha_{j,1} - \alpha_{j,2}^\dagger \alpha_{j,2}) \end{aligned} \quad (\text{A37})$$

is equivalent to a non-Hermitian SSH model

$$\begin{aligned} H_{\text{SSH}} &= \sum_{j=1}^N (\Delta a_j^\dagger b_j + 2\kappa a_{j+1}^\dagger b_j) + \text{H.c.} \\ &+ i\gamma \sum_{j=1}^N (a_j^\dagger a_j - b_j^\dagger b_j). \end{aligned} \quad (\text{A38})$$

Actually, the core matrix of  $H_{\text{ladd}}$  is

$$h_k^{\text{ladd}} = \begin{pmatrix} i\gamma & \Delta + 2\kappa \cos k \\ \Delta + 2\kappa \cos k & -i\gamma \end{pmatrix}. \quad (\text{A39})$$

For  $H_{\text{SSH}}$ , we have the core matrix

$$h_k^{\text{SSH}} = \begin{pmatrix} i\gamma & \Delta + 2\kappa e^{-ik} \\ \Delta + 2\kappa e^{ik} & -i\gamma \end{pmatrix}, \quad (\text{A40})$$

which has the same spectrum with

$$h_k = \begin{pmatrix} \frac{i\gamma}{\sqrt{\Delta^2 + 4\kappa^2 + 4\Delta\kappa \cos k}} & \sqrt{\Delta^2 + 4\kappa^2 + 4\Delta\kappa \cos k} \\ & -i\gamma \end{pmatrix}. \quad (\text{A41})$$

In the case of strong dimerization limit  $\Delta^2 \gg \kappa^2$ , we have

$$\sqrt{\Delta^2 + 4\kappa^2 + 4\Delta\kappa \cos k} \approx \Delta + 2\kappa \cos k \quad (\text{A42})$$

or

$$h_k \approx h_k^{\text{ladd}}. \quad (\text{A43})$$

The spectra of ladder model and SSH model with several  $\gamma$  are shown in Figs. 6(a) and 6(b), respectively. It indicates that two spectra are almost identical.
