(Received 4 February 2020; revised manuscript received 18 April 2020; accepted 6 May 2020; published 26 May 2020)

The topological electronic properties of orthorhombic-phase $Mo₂C$ and $W₂C$ superconductors have been studied based on first-principles electronic structure calculations. Our studies show that both Mo₂C and W₂C are three-dimensional strong topological insulators defined on curved Fermi levels. The topological surface states on the (001) surface of Mo₂C right cross the Fermi level, while those of W₂C pass through the Fermi level with slight electron doping. These surface states hold helical spin textures and can be induced to become superconducting via a proximity effect, giving rise to an equivalent $p + ip$ type superconductivity. Our results show that $Mo₂C$ and $W₂C$ can provide a promising platform for exploring topological superconductivity and Majorana zero modes.

I. INTRODUCTION

The coexistence of superconductivity and topological band structure in a material may induce novel physical phenomena such as topological superconductivity [\[1,2\]](#page-4-0). Topological superconductors can host Majorana zero modes [\[3\]](#page-4-0) that obey non-Abelian statistics and have a potential application in topology-protected quantum computation [\[4\]](#page-4-0). In a conventional *s*-wave superconductor, spins with two degrees are a main obstacle for realizing Majorana zero modes. In contrast, a spin-less superconductor provides an ideal platform for realizing Majorana zero modes, which can either locate at the edge of a one-dimensional (1D) *p*-wave topological superconductor or bind to the magnetic vortices in a twodimensional (2D) $p + ip$ topological superconductor [\[3\]](#page-4-0). Recently, the exploration of topological superconductors has attracted intensive attention in condensed-matter physics and materials communities. Nevertheless, the *p*-wave superconductor viewed as an intrinsic topological superconductor is very rare in nature [\[5\]](#page-4-0).

Several approaches for realizing equivalent topological superconductivity have been proposed based on Fu and Kane's work [\[6\]](#page-4-0) and subsequently confirmed by several experiments $[7-14]$. The first way is to construct a heterostructure composed of a topological insulator and an *s*-wave superconductor, in which the superconductivity in helical topological surface states can be induced via a proximity effect at the interface [\[6,10\]](#page-4-0). Such a heterostructure, however, is confronted with a complex interface effect. The second way is to make a topological material superconducting below a critical temperature by doping or to tune a superconducting material into a topological phase via doping [\[15–18\]](#page-4-0). Nevertheless,

very low [\[19\]](#page-4-0). In addition, a topological material that can be driven into a superconducting phase by pressure or point contact may also realize topological superconductivity [\[20,21\]](#page-4-0). So far, an ideal approach is to find a single compound that possesses both intrinsic superconductivity and nontrivial topo-logical electronic properties [\[11–13,22–25\]](#page-4-0). In such a single compound, the Dirac-type surface states can be guaranteed by topological protection and the superconductivity in the surface states can be induced via a proximity effect due to the intrinsic bulk superconductivity, resulting in an equivalent $p + ip$ type topological superconductivity at the surface.

the inhomogeneity caused by doping is unavoidable and the induced superconducting transition temperature (T_c) is usually

Following this strategy, we have studied the ξ -Fe₂N-type superconducting carbides $Mo₂C$ and $W₂C$ by using firstprinciples electronic structure calculations. We find that both $Mo₂C$ and $W₂C$ are a class of materials with nontrivial topological electronic band structures. Furthermore, previous experiments have shown that the superconducting transition temperatures (T_c) of Mo₂C and W₂C are 7.3 K [\[26\]](#page-4-0) and 4.05 K [\[27\]](#page-4-0), respectively.

II. METHOD

The electronic structures of the ξ -Fe₂N-type (orthorhombic-phase) $Mo₂C$ and $W₂C$ were studied based on the first-principles electronic structure calculations [\[28\]](#page-4-0). The projector augmented-wave method [\[29\]](#page-5-0) as implemented in the VASP package $[30,31]$ was used to describe the core electrons as well as the interaction between the core and the valence electrons. The generalized gradient approximation (GGA) [\[32\]](#page-5-0) of the Perdew-Burke-Ernzernof type was adopted for the exchange correlation functional. The kinetic energy cutoff of the plane-wave basis was set to be 520 eV. A $11 \times 9 \times 11$ *k*-point mesh for Brillouin zone (BZ) sampling and the Gaussian smearing method with a width of 0.05 eV for

FIG. 1. (a) Crystal structure of orthorhombic-phase $Mo₂C$ and $W₂C$. (b) Bulk BZ and projected two-dimensional BZ of the (001) surface. The red lines indicate the high-symmetry paths in the BZ for band structure calculations.

Fermi surface broadening were utilized. Both cell parameters and internal atomic positions were fully relaxed until the forces on all atoms were smaller than 0.01 eV/Å. Once the equilibrium structures were obtained, the electronic structures were further studied with the inclusion of spin-orbit coupling (SOC). The surface states in the projected 2D BZ were studied by using the WannierTools package [\[33\]](#page-5-0). The tight-binding Hamiltonian of the semi-infinite system was constructed by the maximally localized Wannier functions [\[34,35\]](#page-5-0) for the outmost *s*, *p*, and *d* orbitals of the Mo and W atoms and the outmost *s* and *p* orbitals of the C atom generated by the first-principles calculations. The surface states were obtained from the surface Green's function of the semi-infinite system. To simulate the charge doping effect, the total electron number in the unit cell was changed in self-consistent and band structure calculations.

III. RESULTS

The transition metal carbides $Mo₂C$ and $W₂C$ have two phases, namely orthorhombic and hexagonal phases. Here we focus on their orthorhombic phase, which adopts the ξ -Fe₂N crystal structure with space group *Pbcn*. As illustrated in Fig. $1(a)$, the primitive cell includes eight transition metal atoms and four carbon atoms. Each Mo or W atom possesses three C neighbors, while each C atom is coordinated with six Mo or W atoms. The calculated lattice constants are $a = 4.75$ Å, $b = 6.06$ Å, and $c = 5.22$ Å for Mo₂C and $a = 4.75$ Å, $b = 6.10$ Å, and $c = 5.23$ Å for W₂C, which agree well with the experimental values [\[36,37\]](#page-5-0). In Fig. 1(b), the bulk BZ along with the high-symmetry *k* points and the projected 2D BZ of the (001) surface are displayed.

Figures $2(a)$ and $2(c)$ show the band structures along the high-symmetry paths of the BZ and the Fermi surface of $Mo₂C$ calculated without the spin-orbit coupling (SOC), respectively. From the band structure [Fig. $2(a)$], we can see that there are several bands crossing the Fermi level with large dispersions, indicating the metallic behavior of $Mo₂C$. Moreover, the corresponding eight Fermi surface pockets shown in Fig. $2(c)$ demonstrate its three-dimensional (3D) character.

FIG. 2. Electronic band structures of $Mo₂C$ calculated (a) without and (b) with the SOC along the high-symmetry paths of BZ. (c) Fermi surface sheets of $Mo₂C$ calculated without the SOC.

According to the calculated density of states [Fig. $3(a)$], Mo atoms have an essential contribution around the Fermi level in comparison with C atoms, which suggests that the superconductivity in $Mo₂C$ can be attributed to Mo orbitals. The partial density of states shows that five 4*d* orbitals of the Mo atom have similar weights around the Fermi level, which is due to the relatively weak crystal field effect in $Mo₂C$.

On the other hand, a careful examination of the band structure in Fig. $2(a)$ indicates that there are band inversions between the conduction bands and the valence bands, implying that Mo2C may have a nontrivial topological property. Figure $2(b)$ shows the band structure of Mo₂C calculated with the SOC. When the SOC effect is included, the band crossings without the SOC [Fig. $2(a)$] open with a continuous band gap appearing through the whole Brillouin zone [Fig. $2(b)$], for which one opened gap is 11 meV at the Γ point and two opened gaps are 13 and 14 meV around the Z point, respectively. This is because the highest rotationally symmetric operation of the orthorhombic-phase $Mo₂C$ is $C₂$, which cannot protect the band crossing points along the high-symmetry path [\[38\]](#page-5-0). As a result, a curved Fermi level can be defined between the highest valence band (blue color) and the lowest conduction band (red color), and we can further calculate the topological invariant for the occupied bands below the gap to check the topological property of $Mo₂C$. For a 3D system, the topological invariant is defined $[39]$ as Z_2 (v_0 ; $v_1v_2v_3$), where v_0 is a strong topological index and v_1 , v_2 , and v_3 are three weak topological indices [\[40\]](#page-5-0). By using the Wilson loop method [\[41\]](#page-5-0), we obtain the topological invariant Z_2 as $(1; 000)$, which indicates that the orthorhombic-phase Mo2C is a strong topological insulator defined on a curved Fermi surface (see Appendix [A](#page-4-0) for details).

FIG. 3. (a) Total and local density of states for $Mo₂C$ calculated without the SOC. (b) Partial density of states for five 4*d* orbitals of the Mo atom. The Fermi level is set to zero.

One of the most significant phenomena for topologically nontrivial materials is the existence of topological surface states. Figure $4(a)$ shows the band structure of the (001) surface of $Mo₂C$ along the high-symmetry paths in the projected 2D BZ (Fig. [1\)](#page-1-0) calculated with the SOC. The Dirac-type surface states located in the bulk band gap at the \overline{X} point can be clearly resolved and can be detected by an angleresolved photoemission spectroscopy (ARPES) experiment. The surface states just pass through the Fermi level, giving rise to an ellipse surrounding the \overline{X} point. These surface states can hold spin-momentum-locked spin textures as shown in Fig. $4(b)$, which are protected by the time-reversal symmetry [\[42\]](#page-5-0).

We have also studied the electronic structure of the orthorhombic-phase W_2C , which has the same crystal structure as $Mo₂C$. Due to the heavier atomic mass, the W atom has spin-orbit coupling stronger than that of the Mo atom. There are seven bands across the Fermi level (not shown) and the calculated topological invariant Z_2 of the orthorhombic-phase W_2C is (1;000), indicating that W_2C is also a strong topological insulator defined on a curved Fermi surface. Figure $5(a)$ shows the band structure of the (001) surface and the surface states of W_2C . Since there are surface states merging into the bulk states without crossing the Fermi level along the $\overline{\Gamma}$ - \overline{X} path, the surface states do not form a closed contour around the \overline{X} point as shown in Fig. [5\(b\).](#page-3-0) Nevertheless, when the Fermi level is lifted by 0.1 eV via electron doping, the surface states will pass through the Fermi level, giving rise to an ellipse surrounding the X point [Fig. $5(c)$]. Likewise,

FIG. 4. (a) Band structure of the (001) surface of Mo₂C along the high-symmetry paths in the projected 2D BZ (Fig. [1\)](#page-1-0) calculated with the SOC. (b) Surface states with spin textures around the \overline{X} point in the 2D BZ at a fixed energy of E_F . Here the arrows denote the spins' directions.

these surface states can hold spin-momentum-locked spin textures as shown in Fig. $5(d)$. Since both Mo₂C and W₂C are strong topological insulators defined on curved Fermi surfaces, all of their surfaces exhibit topological surface states. As illustrations, we have also investigated the band structures of the (100) and (010) surfaces for $Mo₂C$ and $W₂C$ (see Fig. [7](#page-3-0) in Appendix \bf{B}), where the topological surface states in bulk band gaps can be clearly resolved as well.

IV. DISCUSSION AND SUMMARY

The exploration for a single compound possessing both superconductivity and nontrivial topological properties is important for the realization of topological superconductivity. According to Fu and Kane's proposal [\[6\]](#page-4-0), once the bulks of $Mo₂C$ and $W₂C$ become superconducting below the critical temperatures, their spin-momentum-locked surface states around the Fermi level will open a superconducting gap via the proximity effect. The spin-polarized surface electrons that can be regarded as spinless fermions will thus form the Cooper pairs. In this case, the resulting superconductivity on the surface can be viewed as an equivalent $p + ip$ superconductivity.

FIG. 5. (a) Band structure of the (001) surface of W_2C along the high-symmetry paths in the projected 2D BZ (Fig. [1\)](#page-1-0) calculated with the SOC. (b) Surface states in the 2D BZ at a fixed energy of E_F . (c) Surface states and (d) spin textures around the X point in the 2D BZ at a fixed energy of $E_F + 0.1$ eV. Here the arrows denote the spins' directions.

When an appropriate external magnetic field is applied, Majorana zero modes will be localized in the vortex cores and the zero-bias peak can be observed in a scanning tunneling microscopy experiment. Our theoretical proposals on $Mo₂C$ and W₂C need to be confirmed by further experimental studies.

In real materials, although the Dirac-type surface states are complicated, the key factor is the formation of spinmomentum-locked spin textures as shown in Figs. [4](#page-2-0) and 5. To be a single-compound topological superconductor candidate, we propose that it meet the following criteria: (i) the nontrivial topological surface states locate in the projected bulk band gap and are not buried by bulk states, (ii) these surface states are close to the Fermi level and hold the helical spin texture

FIG. 6. The evolution lines of Wannier centers of bulk $Mo₂C$ in the (a) $k_x = 0$ and (b) $k_x = \pi$ planes, respectively.

FIG. 7. Band structures of the (a) (010) and (b) (100) surfaces of Mo2C, respectively. Band structures of the (a) (010) and (b) (100) surfaces of W_2C , respectively.

around a time-reversal invariant point, and (iii) the superconducting transition temperature of the compound should be as high as possible so that the Majorana zero modes can be separated from other Caroli–de Gennes–Matricon (CdGM) states in the superconducting gap [\[43\]](#page-5-0). In previous studies, several kinds of single compounds have been predicted to be topological superconductors, such as $FeTe_{0.55}Se_{0.45}$ [\[23,24\]](#page-4-0), LiFe_{1–*x*}Co_{*x*}As [\[25\]](#page-4-0), (Li_{0.84}Fe_{0.16})OHFeSe [\[14\]](#page-4-0), CaKFe₄As₄ [\[44\]](#page-5-0), TaSe₃ [\[45\]](#page-5-0), *A*15 system [\[46\]](#page-5-0), PdBi [\[47\]](#page-5-0), *β*-PdBi₂ [\[48,49\]](#page-5-0), β -RhPb₂ [\[50\]](#page-5-0), YPb₃ [\[51\]](#page-5-0), Mg₂Pb [\[52\]](#page-5-0), Au₂Pb [\[53\]](#page-5-0), LuPtBi $[54]$, PbTaSe₂ [\[55\]](#page-5-0), and PbTiSe₂ [\[56\]](#page-5-0), etc. In this work, we propose that $Mo₂C$ and $W₂C$ are also ideal topological superconductor candidates. First, their projected bulk states on the (001) surface have relatively large band gaps (about 1 eV) along the $\overline{\Gamma}$ - \overline{X} - \overline{S} path. As a result, the surface states can be easily detected and resolved in the ARPES experiment. Second, the surface states close to the Fermi level readily become superconducting via a proximity effect. The topological surface states of $Mo₂C$ just cross the Fermi level, while those of W_2C would cross the Fermi level with slight electron doping of 0.8–1.4 electrons per formula unit to lift the Fermi level by 0.1–0.2 eV. Third, the superconducting transition temperature of $Mo₂C$ is 7.3 K, higher than the liquid helium temperature and the T_c 's of many other topological superconductor candidates.

In summary, we have investigated the topological electronic properties and surface states of the orthorhombic-phase $Mo₂C$ and $W₂C$ superconductors by using first-principles electronic structure calculations. The calculated topological invariant Z_2 of (1;000) indicates that they are both strong topological insulators defined on curved Fermi levels. The nontrivial topological surface states are within the bulk band gaps and these Dirac-type surface states hold helical spin textures. Considering the fact that $Mo₂C$ and $W₂C$ had been reported to be superconductors in experiments, their bulk superconductivity may induce superconductivity in the nontrivial topological surface states via a proximity effect. Thus the orthorhombic-phase $Mo₂C$ and $W₂C$ provide an appropriate platform for investigating the interplay between superconductivity and topological properties as well as for manipulating Majorana zero modes in future experiments [\[57\]](#page-5-0).

and $6(b)$ show the evolution lines of Wannier centers in the $k_x = 0$ and $k_x = \pi$ planes of the bulk BZ of Mo₂C, respectively. The evolution lines cross the reference line (red dashed line) an odd number of times in the $k_x = 0$ plane with the Z_2 index being 1 and an even number of times in the $k_x = \pi$ plane with the Z_2 index being 0, leading to the strong topological index $v_0 = 1$. Therefore, Mo₂C is a 3D strong topological insulator. Likewise, W_2C is a 3D strong topological insulator. We have checked the topological properties by using a recently developed functional at the meta-GGA level, namely, the strongly constrained and appropriately normed semilocal density functional [\[58\]](#page-5-0), which gives the consistent results.

APPENDIX B

Here we show the surface states of $Mo₂C$ and $W₂C$ on another two surfaces. Figures $7(a)$ and $7(b)$ respectively show the band structures of the (010) and (100) surfaces of $Mo₂C$. Figures $7(c)$ and $7(d)$ respectively show those of W₂C. The surface states in the projected bulk band gaps around the X point of the 2D BZ can be clearly resolved.
