(Received 23 April 2023; revised 11 September 2023; accepted 21 September 2023; published 10 October 2023)

Zero thermal expansion (ZTE) is a rare phenomenon of great importance in the field of materials design.  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ) exhibit near-zero thermal expansion. In this work, we perform first principles calculations in  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ) and  $Zr_2(PO_4)_3$  compounds to elucidate the effects of  $A$  cations on the thermal expansion behavior. Structural and vibrational analysis shows that the near-zero thermal expansion is strongly related to the dynamics of the “lantern” units of  $[Zr_2(PO_4)_3]$ , where the  $ZrO_6$  and  $PO_4$  polyhedra are rigid. The calculated Grüneisen parameters reveal that different  $A$ -site alkali metal atoms heavily affect the phonon modes of  $A$  atoms and the rotation of  $ZrO_6$  and  $PO_4$  polyhedra, as well as the acoustic phonon modes, thus resulting in a different thermal expansion behavior of  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ). The absence of  $A$  atoms in  $Zr_2(PO_4)_3$  facilitates the structural flexibility and therefore the occurrence of a stronger negative thermal expansion. This work provides insights into the modulation of thermal expansion of these  $NaZr_2(PO_4)_3$ -type compounds.

## I. INTRODUCTION

Zero thermal expansion (ZTE, i.e., volume remains constant within a certain temperature range) is a rare and interesting phenomenon [1]. Due to their excellent dimensional stability, ZTE materials are important for materials design, such as in high-precision applications. Some examples of single-phase near ZTE materials are  $Zn_4B_6O_{13}$ , which exhibits a solid cagelike structure, and the coupled rotation of  $BO_4$  tetrahedra with the Zn-O bond constraint leads to ZTE [2,3], and  $Ta_2Mo_2O_{11}$  where the positive thermal expansion (PTE) intralayers are balanced by negative thermal expansion (NTE) interlayers thus resulting in overall ZTE [4]. Very interesting is the case of nano  $ScF_3$ , whose ZTE originates from the suppression of transverse vibrations of F atoms [5]. Other typical ZTE materials are  $TaO_2F$  [6],  $ZrMgMo_3O_{12}$  [7],  $MgZrF_6$  [8],  $Fe[Co(CN)_6]$  [9], and  $Sc_{1.5}Al_{0.5}W_3O_{12}$  [10]. However, the number of ZTE materials is low and not sufficient to satisfy the application needs. With the discovery of NTE phenomenon (shrink upon heating) [11–13], the opportunity to regulate the thermal expansion of materials has become feasible. In principle, ZTE materials can be obtained by compounding NTE and PTE materials, just like  $Mn_3Cu_{0.5}Ge_{0.5}N/Cu$  or  $ZrO_2/ZrW_2O_8$  [14,15].

Chemical substitution is a common way to regulate the thermal expansion of materials. For example, with the change

of  $M$  and  $A$  atoms in  $MZrF_6$  ( $M = Ca, Mn, Fe, Co, Ni, Zn$ ) and  $A_2O(PO_4)_2$  ( $A = Th, U, Zr$ ), the thermal expansion can be modulated from NTE to PTE [16,17]. In  $Ni_2P_2O_7$ , replacing Ni with different ratios of Mn, we can regulate the phase transition temperature and broaden the NTE temperature region. In particular,  $Ni_{1.4}Mn_{0.6}P_2O_7$  exhibits near ZTE in the temperature range 180–420 K [18]. In framework structures, the introduction of guest species is also an effective way to control thermal expansion. For instance, ZTE can be obtained by insertion of  $Na^+$  ions and  $H_2O$  molecules in  $GaFe(CN)_6$  and  $TiCo(CN)_6$ , respectively, thanks to the inhibition of the transverse vibrations of CN bridge atoms [19,20]. Also the transition from NTE to ZTE to PTE in  $ScF_3$  is achieved by adjusting the amount of inserted  $Li^+$  ions which suppresses the transverse vibrations of F atoms [21]. In general, either chemical substitution or introduction of guest species affect crystal structure flexibility, chemical bonds, atomic vibrations, and magnetic and electronic properties, and thus can modulate the thermal expansion behavior of materials.

$NaZr_2(PO_4)_3$  type compounds (NZP) are of wide interest for their negative or low thermal expansion coefficient, fast ionic conductivity, tunable anisotropic thermal expansion, facile ionic substitution, and thermal stability [22–24]. The chemical formula of NZP can be expressed as  $M1M2L_2(TO_4)_3$ . Two  $LO_6$  octahedra and three  $TO_4$  tetrahedra form the so-called “lantern” unit of  $[L_2(TO_4)_3]$ , which are aligned along the  $c$  axis and form holes in the crystal structure. There are two types of hole locations, related to  $M1$  and  $M2$  cations, where the  $M1$  site can be replaced by alkali metal ions and the  $M2$  site, in most cases, is unoccupied [25]. NZP materials generally exhibit anisotropic thermal expansion with

\*qsun@zzu.edu.cn

†qilonggao@zzu.edu.cn

positive expansion in the  $c$  axis and negative expansion in the  $a$  ( $b$ ) axis [26]. Taking  $\text{NaZr}_2(\text{PO}_4)_3$  as an example, where the Na ions occupy only the  $M1$  sites, Alamo argued that the expansion of the Na-O bonds contributes significantly to the thermal expansion of NZP materials: the Na-O bonds expand and the space in the  $M1$  sites along the  $c$  axis increases, thus causing the expansion of the crystallographic  $c$  axis and the coupled rotations of the  $\text{ZrO}_6$  octahedra and  $\text{PO}_4$  tetrahedra connected by shared angles, thus creating the conditions to have NTE along the  $a$  ( $b$ ) axis [27]. Moreover, it was shown that the thermal expansion of the NZP family is heavily influenced by the cations at the  $M$  site. For example, in  $\text{Na}_{1-x}\text{Nb}_x\text{Zr}_{2-x}(\text{PO}_4)_3$ ,  $\text{Na}_{1+x}\text{Zr}_2(\text{Si}_x\text{P}_{3-x})\text{O}_{12}$ , and  $\text{Na}_{1+x}\text{Y}_x\text{Zr}_{2-x}(\text{PO}_4)_3$ , for  $0 \leq x \leq 1$ , the Na ions occupy only the  $M1$  sites, and as the Na content increases, the  $c$  axis and its thermal expansion increase significantly. When  $x > 1$ , the  $M1$  sites are fully occupied (except for  $\text{Na}_{1+x}\text{Zr}_2(\text{Si}_x\text{P}_{3-x})\text{O}_{12}$ ) and  $M2$  sites start to be occupied. As the Na content increases, the  $a$  axis and its thermal expansion coefficient increase. However, in this case, the thermal expansion caused by the occupation of the  $M2$  sites leads to the contraction of the  $\text{PO}_4$  tetrahedra, resulting in a low thermal expansion of the  $a$  ( $b$ ) axis [28]. In particular, when the  $M$  sites are not occupied by ions, such as  $\text{TaTi}(\text{PO}_4)_3$  and  $\text{NbTi}(\text{PO}_4)_3$ , more free spaces in the crystal structure lead to a more flexible structure, which facilitates rotational motion between the polyhedra and the occurrence of negative thermal expansion behavior [29,30].

It is also important to point out that the  $M$ -site ionic radius influences the thermal expansion. For example, in the  $M\text{Hf}_2(\text{PO}_4)_3$  series, where  $M = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ , when the  $M$  site is occupied by a large ion, the O-P-O bond angle expands in the  $c$  axis and the bridging  $\text{PO}_4$  tetrahedra contract along the  $a$ -axis direction, promoting a decrease of the average thermal expansion [31]. The  $M$  site can also be occupied by a two-valent cation, such as  $M_{0.5}\text{Zr}_2(\text{PO}_4)_3$  ( $M = \text{Ca}, \text{Sr}, \text{Ba}$ ). In this family, to balance the valence, only one  $M$  atom is included in each primitive cell. The positive thermal expansion of  $M_{0.5}\text{Zr}_2(\text{PO}_4)_3$  ( $M = \text{Ca}, \text{Sr}, \text{Ba}$ ) gradually increases as the radius of  $M^{2+}$  increases and  $\text{BaZr}_2(\text{PO}_4)_3$  exhibits a different thermal expansion behavior than most NZP compounds:  $\alpha_c < 0$  and  $\alpha_a, \alpha_b > 0$  [32,33]. For the  $A\text{Zr}_2(\text{PO}_4)_3$  ( $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) family, the  $M1$  sites are completely occupied by  $A$  cations and the average thermal expansion coefficient  $\alpha_{av}$  [ $\alpha_{av} = (\alpha_a + \alpha_b + \alpha_c)/3$ ] of  $\text{NaZr}_2(\text{PO}_4)_3$ ,  $\text{KZr}_2(\text{PO}_4)_3$ ,  $\text{RbZr}_2(\text{PO}_4)_3$ ,  $\text{CsZr}_2(\text{PO}_4)_3$  is  $4.5 \times 10^{-6} \text{ K}^{-1}$ ,  $-0.4 \times 10^{-6} \text{ K}^{-1}$ ,  $-0.36 \times 10^{-6} \text{ K}^{-1}$ ,  $0.4 \times 10^{-6} \text{ K}^{-1}$  in the temperature range 293–1273 K, respectively [34,35]. The thermal expansion of  $A\text{Zr}_2(\text{PO}_4)_3$  ( $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) changes irregularly as the radius of the  $A$ -site cation increases ( $\text{Na}^+ < \text{K}^+ < \text{Rb}^+ < \text{Cs}^+$ ). So far, it is not clear how the  $A$ -site cation affects the thermal expansion behavior of the  $A\text{Zr}_2(\text{PO}_4)_3$  family.

In this work, to clarify the different effect of  $A$  cations in the thermal expansion of the  $A\text{Zr}_2(\text{PO}_4)_3$  family, first-principles calculations have been performed for the cases  $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$  and in the absence of  $A$  atoms. The structural and dynamic properties were investigated to reveal the factors that promote the occurrence of near-zero thermal expansion. By comparing the differences in Grüneisen parameters, the influence of the various  $A$  atoms on specific phonon

modes and thus on the different thermal expansion behavior of  $A\text{Zr}_2(\text{PO}_4)_3$  compounds has been clarified.

## II. COMPUTATIONAL DETAILS

All calculations were carried out within the context of density functional theory (DFT) by using the Vienna Ab initio Simulation Package (VASP) [36]. The ion-electron interaction was described using the projector augmented wave (PAW) function approach. The exchange and correlation effects were included within the Perdew-Burke-Ernzerhof (PBE) generalized gradient approximation (GGA) [37]. The wave functions for the primitive cell of  $A\text{Zr}_2(\text{PO}_4)_3$  ( $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) and  $\text{Zr}_2(\text{PO}_4)_3$  are expanded by plane waves up to an energy cutoff of 600 eV. The integration over the Brillouin zone is sampled with a  $k$ -point grid of  $4 \times 4 \times 4$ , generated automatically by the Monkhorst-Pack approach [38]. The convergence criteria for the total energy and ionic forces were set to  $10^{-8}$  eV and  $10^{-4}$  eV/Å, respectively.

In order to obtain the phonon properties by the PHONOPY code [39], we have picked a  $2 \times 2 \times 2$  supercell with  $2 \times 2 \times 2$   $k$ -point mesh and used the finite displacement method developed in VASP to calculate the force constants [40]. The thermodynamic properties have been calculated within the quasiharmonic approximation (QHA) [41]. The QHA theory contains only implicit anharmonicity (i.e., the volume dependence of phonon frequencies) and ignores explicit anharmonicity (i.e., phonon-phonon anharmonic interactions, which may contribute significantly at high temperature) [42,43]. Therefore, this approach has been widely used to calculate the thermal expansion properties of materials well below their melting points [44–49]. The Helmholtz free energy versus volume ( $F-V$ ) for ten different volumes around the optimized equilibrium volume has been fitted by the Vinet equation of states (EOS) [50] in order to obtain the thermal expansion coefficient (CTE). The mode Grüneisen parameters have been calculated according to the definition  $\gamma_{q,j} = -\frac{V}{\omega_{q,j}} \frac{\partial \omega_{q,j}}{\partial V}$  [51].

## III. RESULTS AND DISCUSSION

### A. Crystal structure and thermal expansion properties

The crystal structure of trigonal  $A\text{Zr}_2(\text{PO}_4)_3$  ( $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) with space group  $R\bar{3}C$  is shown in Fig. 1(a): two  $\text{ZrO}_6$  octahedra are connected by three  $\text{PO}_4$  tetrahedra to form a “lantern” unit of  $[\text{Zr}_2(\text{PO}_4)_3]$  [for clarity, Fig. 1(b) shows two neighboring lantern units], with the  $A$ -site alkali metal atom located between the two lantern units along the  $c$  axis. The structure of  $A\text{Zr}_2(\text{PO}_4)_3$  ( $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) has been optimized and the calculated lattice constants and bond lengths are in good agreement with the experimental values [52,53] as reported in Table I. In particular, it can be observed that the  $a$  axis gradually decreases and the  $c$  axis gradually increases as the radius of the  $A$ -site cation increases ( $\text{Na}^+ < \text{K}^+ < \text{Rb}^+ < \text{Cs}^+$ ). We have also simulated the crystal structure without  $A$  atoms [i.e.,  $\text{Zr}_2(\text{PO}_4)_3$ , not successfully synthesized experimentally], and the optimized crystal structure is basically unchanged as shown in Fig. 1(c). The calculated phonon spectra without imaginary frequencies (see below for detailed information) prove that the structure is stable.

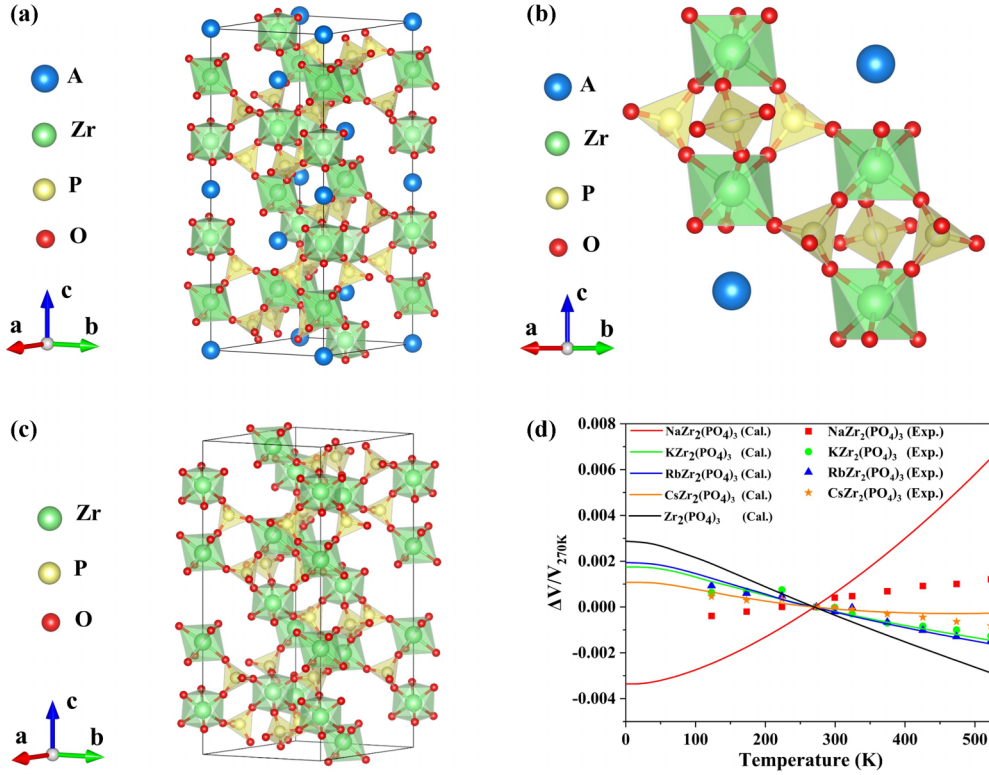

FIG. 1. (a) Crystal structure of  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ); (b) two neighboring lantern units of  $[Zr_2(PO_4)_3]$ ; (c) crystal structure of  $Zr_2(PO_4)_3$ ; (d) calculated (lines) and experimental (symbols) [54] relative thermal expansion of  $AZr_2(PO_4)_3$  and  $Zr_2(PO_4)_3$ .

The relative volume thermal expansion of  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ) and  $Zr_2(PO_4)_3$  has been calculated in the temperature range 0–520 K and compared with the experimental data [54], as shown in Fig. 1(d). The calculated linear CTE (approximated as  $\alpha_l = \frac{\alpha_V}{3}$ ) and experimental average CTE are listed in Table II. The calculated values are fully consistent with the experimental data, except for the overestimation of the PTE of  $NaZr_2(PO_4)_3$ . Indeed, in the low temperature region 0–520 K, the PTE of  $NaZr_2(PO_4)_3$ , the NTE of  $KZr_2(PO_4)_3$  and  $RbZr_2(PO_4)_3$ , and the lower NTE of  $CsZr_2(PO_4)_3$  have been reproduced. Finally, Table II also reports the calculated elastic constants and bulk modulus, whose results are similar to those calculated by Kamali *et al.* [55].

The calculated charge densities (Fig. 2) indicate that all Zr-O and P-O bonds exhibit covalent bonding properties, resulting in rigid  $ZrO_6$  and  $PO_4$  polyhedra (in particular the

$PO_4$  tetrahedra will be highly rigid due to the short P-O bonds and the localized charge density). When the  $A$  element changes, the Zr-O and P-O bond lengths and charge density distributions are very similar, demonstrating that the different  $A$  element does not affect the Zr-O and P-O bond properties much. Thus, the lantern unit  $[Zr_2(PO_4)_3]$  formed by the rigid  $ZrO_6$  and  $PO_4$  polyhedra is very solid and facilitates the near-zero thermal expansion behavior of  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ).

## B. Phonon properties

The thermal expansion of materials with framework structures is closely related to phonon properties. The phonon dispersion curves and the density of vibrational states of these five compounds are shown in Fig. 3.  $AZr_2(PO_4)_3$  ( $A = Na, K,$

Rb, Cs) present similar phonon spectra [see Figs. 3(a)–3(d)], which can be divided in three regions: low frequency (0–12.5 THz), middle frequency (15–20 THz), and high frequency (27.5–35 THz). It can be observed that the vibrations of the A-site alkali metal atoms are mainly located in the ultralow frequency region, and the vibrational contribution becomes more concentrated at lower frequencies as the mass of the A atom increases. Also, the vibrations of the Zr atoms occur mainly in the low frequency region, with a weak contribution in the middle frequency region. The P and O atoms contribute in the whole frequency region, with a stronger contribution from O atoms. An interesting aspect, Fig. 3(e) indicates that the frequencies of all phonon modes in  $Zr_2(PO_4)_3$  are lowered compare to  $AZr_2(PO_4)_3$  compounds, and the density of states of Zr, P, and O atoms is similar to that of  $AZr_2(PO_4)_3$ .

We have analyzed the eigenvectors of all phonon modes at the  $\Gamma$  point of the Brillouin zone and calculated the corresponding square displacements ( $u_j^2 = \frac{|e_j|^2}{m_j}$ ) [56] of the different types of atoms to investigate the vibrational motion, as shown in Fig. 4.  $AZr_2(PO_4)_3$  ( $A = Na, K, Rb, Cs$ ) and  $Zr_2(PO_4)_3$  exhibit similar vibrational properties. The phonon modes in the frequency range 0–8 THz correspond to coupled rotations (RUM) and bending motions of  $ZrO_6$  and  $PO_4$  polyhedra (mainly contributing to NTE), vibrations of A atoms, and translational motions of  $PO_4$  polyhedra and Zr atoms. In the frequency range 8–19 THz, the phonon modes mainly contribute to PTE and are associated to the bending of Zr-O2-

P and Zr-O1-P bonds and motions of P atoms. The phonon modes from 28–35 THz all contribute to the PTE and are associated to the stretching motion of the P-O bonds.

### C. Effect of A-site alkali metal atoms on the thermal expansion

In quasiharmonic approximation the contribution of the different phonon modes to the thermal expansion depends on the positive or negative value of the corresponding mode Grüneisen parameter: the larger the negative value of the mode Grüneisen parameter, the stronger the contribution to the NTE. In  $AZr_2(PO_4)_3$  and  $Zr_2(PO_4)_3$  compounds, all phonon modes are in the middle and high frequency region with low positive values of Grüneisen parameter which will not contribute to the anomalous thermal expansion, so we focus on the mode Grüneisen parameter in the low frequency region as shown in Fig. 5. It is clear that the phonon modes of  $KZr_2(PO_4)_3$ ,  $RbZr_2(PO_4)_3$ , and  $Zr_2(PO_4)_3$  with negative Grüneisen parameters dominate from 0 to 11 THz [see Figs. 5(b), 5(c), and 5(e)], corresponding to the NTE behavior of these three compounds from 0 to 520 K. Interestingly, the three acoustic phonon branches also contribute to the NTE. In comparison, the phonon modes of  $CsZr_2(PO_4)_3$  contribute less to the NTE in the low frequency region [see Fig. 5(d)], for example, the negative mode Grüneisen parameters are weakened and the acoustic modes contribute mainly to the PTE, leading to a very weak NTE. In  $NaZr_2(PO_4)_3$ , the phonon

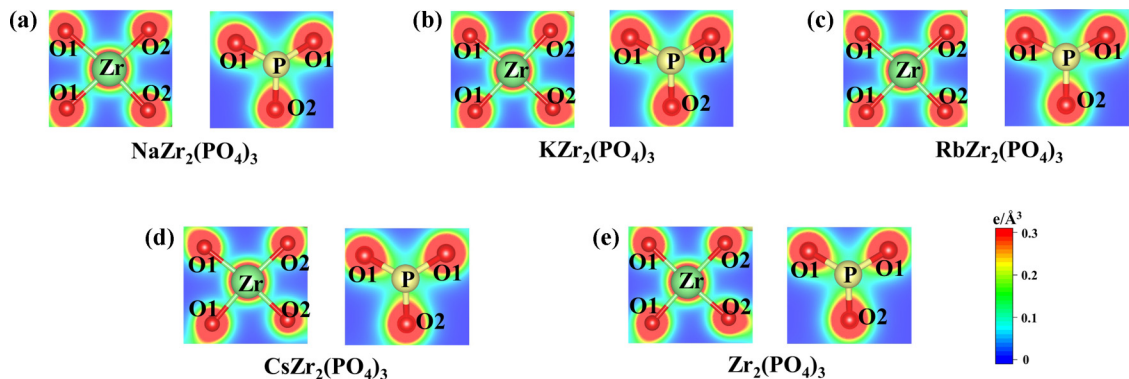

FIG. 2. Calculated charge density of (a)  $NaZr_2(PO_4)_3$ , (b)  $KZr_2(PO_4)_3$ , (c)  $RbZr_2(PO_4)_3$ , (d)  $CsZr_2(PO_4)_3$ , and (e)  $Zr_2(PO_4)_3$ .

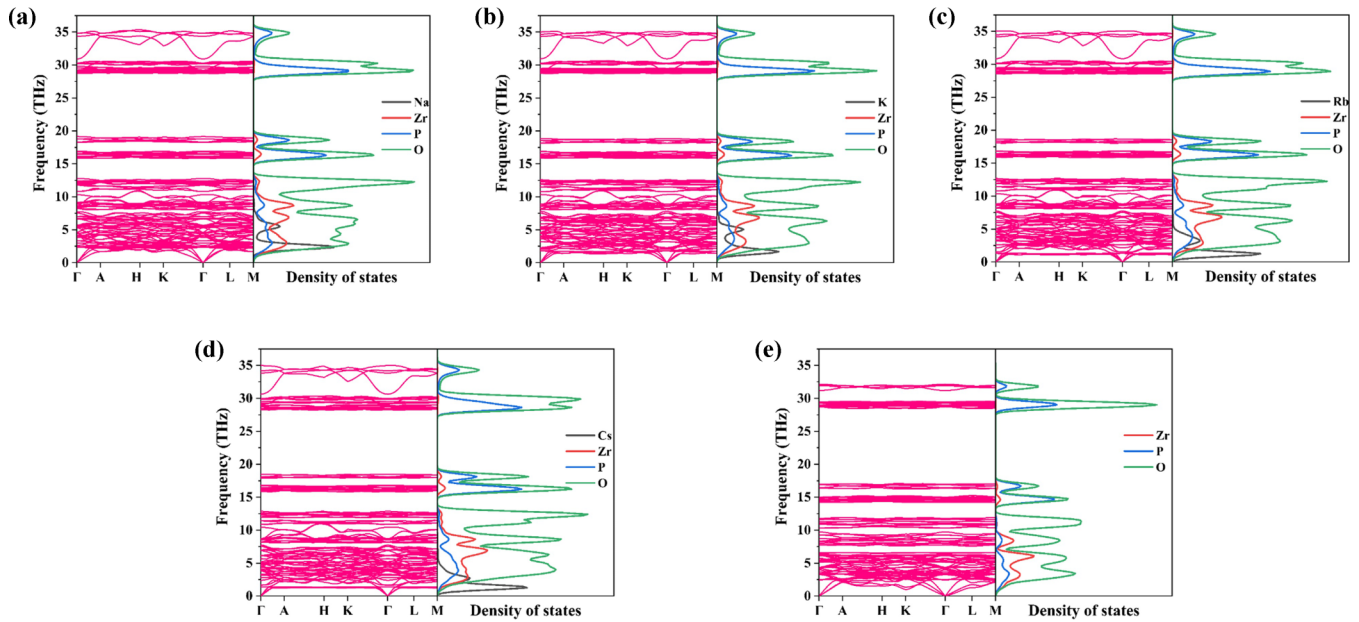

FIG. 3. Calculated phonon dispersion curves and phonon density of states for (a)  $\text{NaZr}_2(\text{PO}_4)_3$ , (b)  $\text{KZr}_2(\text{PO}_4)_3$ , (c)  $\text{RbZr}_2(\text{PO}_4)_3$ , (d)  $\text{CsZr}_2(\text{PO}_4)_3$ , and (e)  $\text{Zr}_2(\text{PO}_4)_3$ .

modes that contribute to the PTE dominate from 0 to 11 THz [see Fig. 5(a)], consistent with its PTE nature.

To obtain more detailed information, we have extracted the Grüneisen parameters of all phonon modes within a  $30 \times 30 \times 30$  grid in the Brillouin zone and processed them into point density maps for the low frequency region (0–8 THz), as shown in Fig. 6. Figure 6(a) shows that a large number of optical phonon modes of  $\text{NaZr}_2(\text{PO}_4)_3$  near 2.4 THz have a positive Grüneisen parameter and so contribute significantly to the PTE, and these vibrational modes involve the motion of Na atoms. Differently, in  $\text{KZr}_2(\text{PO}_4)_3$  and  $\text{RbZr}_2(\text{PO}_4)_3$ ,

the phonon modes where K and Rb play a dominant role [see Figs. 6(b) and 6(c), at about 1.7 and 1.5 THz, respectively] have negative Grüneisen parameters and therefore contribute to NTE. Figure 6(d) shows that the phonon modes related to Cs atoms near 1.3 THz contribute weakly to the PTE.

The eigenvectors of the phonon mode of  $\text{AZr}_2(\text{PO}_4)_3$  ( $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) in which the  $A$  atom plays a dominant role at the  $\Gamma$  point (the  $E_u$  mode as an example) are shown in Fig. 7(a). In addition, the phonon modes in  $\text{AZr}_2(\text{PO}_4)_3$  and  $\text{Zr}_2(\text{PO}_4)_3$  that contribute most to the NTE are the rotational coupling motion of  $\text{ZrO}_6$  and  $\text{PO}_4$  polyhedron, which are

The colored scale ranges from blue for positive Grüneisen parameters, to red for negative Grüneisen parameters.

RUM and give rise to the contraction along the  $a$  and  $b$  axes; the eigenvectors of this vibrational mode (the  $A_{2g}$  mode at the  $\Gamma$  point as an example) are shown in Fig. 7(b). The Grüneisen

parameters of these two representative modes are also listed in Table III. From Figs. 6(b) and 6(c), it is clear that the coupled rotational modes in  $\text{KZr}_2(\text{PO}_4)_3$  and  $\text{RbZr}_2(\text{PO}_4)_3$  (at about

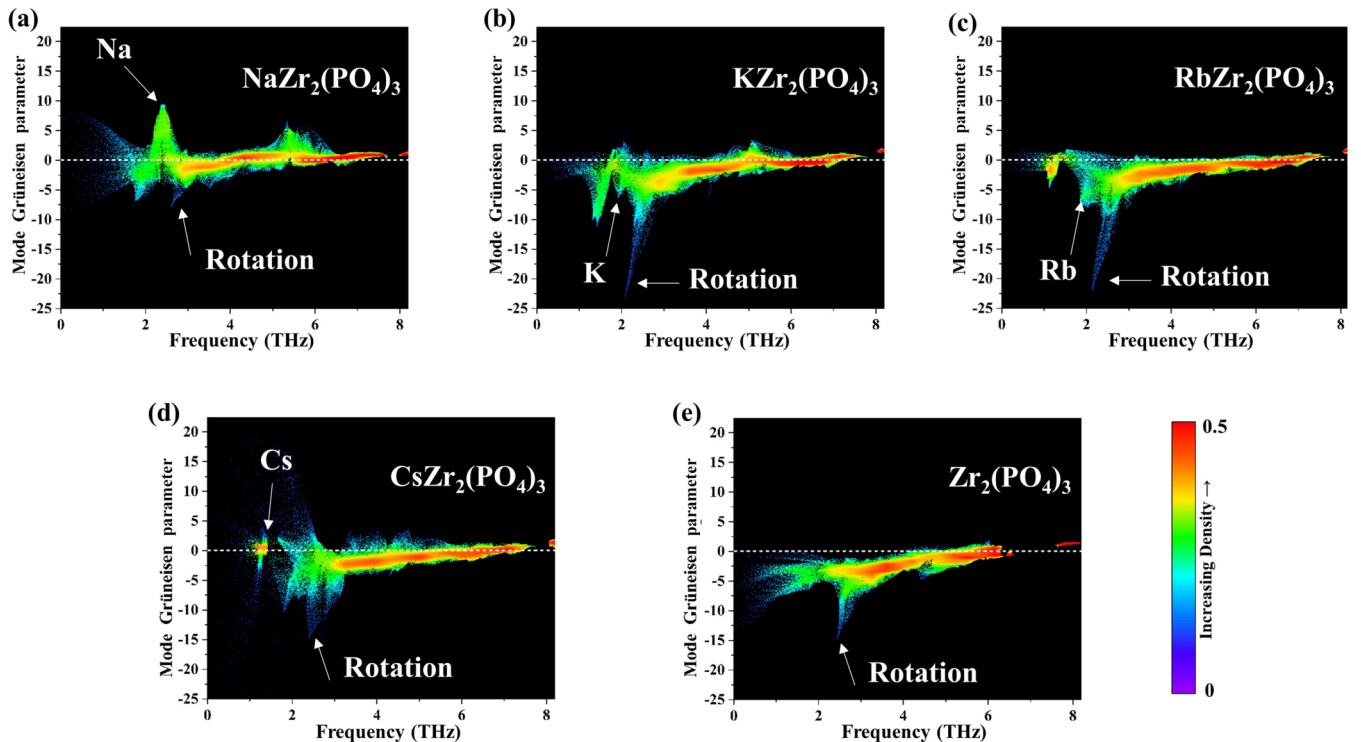

FIG. 6. The point density map of mode Grüneisen parameters in (a)  $\text{NaZr}_2(\text{PO}_4)_3$ , (b)  $\text{KZr}_2(\text{PO}_4)_3$ , (c)  $\text{RbZr}_2(\text{PO}_4)_3$ , (d)  $\text{CsZr}_2(\text{PO}_4)_3$ , and (e)  $\text{Zr}_2(\text{PO}_4)_3$  in the low frequency range 0–8 THz.

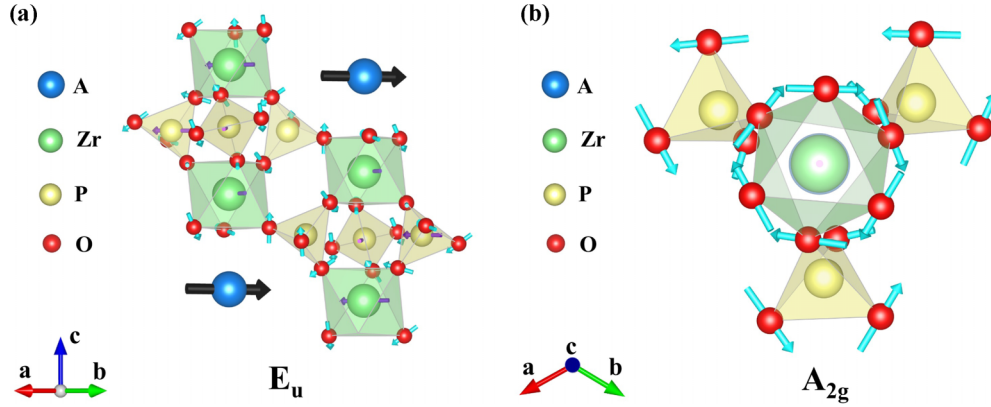

FIG. 7. Eigenvectors of the  $E_u$  and  $A_{2g}$  modes in  $AZr_2(PO_4)_3$  ( $A = \text{Na, K, Rb, Cs}$ ) and  $Zr_2(PO_4)_3$ .

2.1 THz) have the largest negative Grüneisen parameters and contribute the most to the NTE. In contrast, the coupled rotational modes in  $CsZr_2(PO_4)_3$  [see Fig. 6(d), at around 2.4 THz] contribute less to NTE and that of  $NaZr_2(PO_4)_3$  [see Fig. 6(a), around 2.6 THz] even less. To summarize the above analysis, when the A-site alkali metal ion changed, the contribution of specific three phonon models [(1) the mode dominated by A-site alkali metal ions; (2) RUM, i.e., rotation modes of  $ZrO_6$  octahedron and  $PO_4$  tetrahedron; (3) acoustic phonon modes] to the NTE followed the order  $KZr_2(PO_4)_3 \approx RbZr_2(PO_4)_3 > CsZr_2(PO_4)_3 > NaZr_2(PO_4)_3$ , resulting in  $KZr_2(PO_4)_3$  and  $RbZr_2(PO_4)_3$  exhibiting similar low NTE properties,  $CsZr_2(PO_4)_3$  exhibiting very weak NTE properties, and  $NaZr_2(PO_4)_3$  exhibiting low PTE properties. In addition, Figs. 5(e) and 6(e) show that the number of phonon modes with negative Grüneisen parameter are higher when the A-site alkali metal ion is not present [i.e.,  $Zr_2(PO_4)_3$ ]. The frequency of all phonon modes in  $Zr_2(PO_4)_3$  were decreased [see Fig. 3(e)], resulting in easier excitation of phonon modes which contribute to NTE, thus  $Zr_2(PO_4)_3$  exhibits relatively strong NTE properties.

Finally, to evaluate the overall thermal expansion, we have calculated the overall Grüneisen parameter  $\bar{\gamma}$  which represents the weighted sum of all phonon modes excited at a certain temperature. Figure 8 shows that the calculated  $\bar{\gamma}$  is consistent with the thermal expansion behavior of the five compounds here investigated:  $\bar{\gamma}$  is negative in  $KZr_2(PO_4)_3$ ,  $RbZr_2(PO_4)_3$ ,  $CsZr_2(PO_4)_3$ , and  $Zr_2(PO_4)_3$ , and positive in  $NaZr_2(PO_4)_3$ . In particular,  $CsZr_2(PO_4)_3$  exhibits the smallest negative value of  $\bar{\gamma}$ , in accordance with its smallest NTE,

TABLE III. Grüneisen parameters of the  $E_u$  and  $A_{2g}$  modes in  $AZr_2(PO_4)_3$  ( $A = \text{Na, K, Rb, Cs}$ ) and  $Zr_2(PO_4)_3$ .

	$E_u$		$A_{2g}$	
	$\omega$ (THz)	$\gamma_{q,j}$	$\omega$ (THz)	$\gamma_{q,j}$
$NaZr_2(PO_4)_3$	2.4	9.5	2.6	-7.8
$KZr_2(PO_4)_3$	1.8	1.5	2.1	-23.1
$RbZr_2(PO_4)_3$	1.3	1.0	2.1	-21.9
$CsZr_2(PO_4)_3$	1.4	1.3	2.4	-14.7
$Zr_2(PO_4)_3$			2.4	-14.8

while  $KZr_2(PO_4)_3$  and  $RbZr_2(PO_4)_3$  show a similar negative value of  $\bar{\gamma}$ , consistent with their similar low NTE. Finally,  $Zr_2(PO_4)_3$  shows the most negative value of  $\bar{\gamma}$  indicating the largest NTE, and  $NaZr_2(PO_4)_3$  exhibits a positive  $\bar{\gamma}$  in agreement with its PTE behavior.

#### IV. CONCLUSIONS

In summary,  $AZr_2(PO_4)_3$  ( $A = \text{Na, K, Rb, Cs}$ ) and  $Zr_2(PO_4)_3$  compounds have been investigated by first principles calculations to clarify their different low thermal expansion behavior and the effect of the A-site alkali metal atoms on the thermal expansion. The calculated charge density indicates that all Zr-O and P-O bonds are covalent, resulting in a rigid  $ZrO_6$  octahedra and  $PO_4$  tetrahedra of the  $[Zr_2(PO_4)_3]$  lantern units. This is an important aspect which can be related to the presence of the low thermal expansion behavior. The vibrational analysis shows that the phonon modes in the low frequency region (0–8 THz) mainly contribute to the negative thermal expansion, in particular the coupled rotational modes

FIG. 8. Overall Grüneisen parameter  $\bar{\gamma}$  calculated in  $AZr_2(PO_4)_3$  compounds ( $A = \text{Na, K, Rb, Cs}$ ) and  $Zr_2(PO_4)_3$  as a function of temperature.

of  $\text{ZrO}_6$  and  $\text{PO}_4$  polyhedra. The calculated Grüneisen parameters reveal that when the *A*-site alkali metal ion changed, the contribution of specific three phonon models [(1) the mode dominated by *A*-site alkali metal ions; (2) rotation modes of  $\text{ZrO}_6$  octahedron and  $\text{PO}_4$  tetrahedron; (3) acoustic phonon modes] to NTE followed the order  $\text{KZr}_2(\text{PO}_4)_3 \approx \text{RbZr}_2(\text{PO}_4)_3 > \text{CsZr}_2(\text{PO}_4)_3 > \text{NaZr}_2(\text{PO}_4)_3$ , resulting in  $\text{KZr}_2(\text{PO}_4)_3$  and  $\text{RbZr}_2(\text{PO}_4)_3$  exhibiting similar low NTE properties,  $\text{CsZr}_2(\text{PO}_4)_3$  exhibiting very weak NTE properties, and  $\text{NaZr}_2(\text{PO}_4)_3$  exhibiting low PTE properties. When the *A* atom is absent, the structure flexibility increases result in the number of phonon modes contributing to the NTE increasing and becoming more easily excited,

promoting the occurrence of the NTE. These results help us to understand the regulation of thermal expansion in NZP-type materials.
