ticularly important for applications to experiment.

The angle dependence of transition fields can be obtained for comparison with experiments on single crystals, and if only the *c* axis of the sample is defined, comparisons with experiment may be made by numerical averaging of the solutions over all in-plane angles. The material VF₂, ^{13,14} a planar spiral with $q_0 = 96^\circ$, should be a good subject for this type of study. High-field magnetization $(H \perp c \text{ axis})$ at $T \ll T_N = 7 \,^\circ \text{K}$ on this compound would permit an instructive application of the theory here described; behavior similar to that depicted in

Metallic Alloys and Exchange-Enhanced Paramagnetism. Application to Rare-Earth–Cobalt Alloys

D. Bloch and R. Lemaire

Laboratoire d'Electrostatique et de Physique du Métal, Centre National de la Recherche Scientifique, 38-Grenoble-Gare, France (Received 30 March 1970)

A phenomenological theory is presented of the magnetic properties of two-component alloys, one of whose components has a permanent magnetic moment, and the other an exchange-enhanced paramagnetic susceptibility. The paramagnetic susceptibility, magnetic-ordering temperature, and magnetization at low temperature are discussed in terms of this theory, and the results obtained are applied to cubic alloys ACo_2 between rare earth (A) and cobalt.

INTRODUCTION

The behavior of intermetallic alloys between rare earths and transition metals is often complex.¹ Cobalt does not possess a magnetic moment in $\dot{Y}Co_2$ or LuCo₂. In the alloys with magnetic rare earths, the magnetic moment of cobalt varies with the spin of the rare earth. In GdCo₂ or TbCo₂, the magnetic moments of the rare-earth and cobalt atoms are antiparallel, whereas in NdCo₂ or PrCo₂ they are ferromagnetically aligned.²

We present a phenomenological theory for these alloys, and using this theory we study their para-

magnetic susceptibility, magnetic-ordering temperature, and magnetization at low temperature.

I. MODEL AND ITS MAIN CONSEQUENCES

We consider an alloy formed with two types of atoms, A and B, located in two different crystallographic sites. We assume that A possesses a welllocalized magnetic moment and that B gives rise, in the crystal, to electronic energy bands leading to an exchange-enhanced paramagnetic susceptibility. In the high-temperature range, the magne-

⁹T. R. McCalla, Introduction to Numerical Methods and Fortran Programming (Wiley, New York, 1967), Chap. 3, p. 92.

tizations of A and B atoms, in an applied magnetic field H, are

$$M_{A} = (C_{A}/T)(H + n_{AA}M_{A} + n_{AB}M_{B}) , \qquad (1)$$

$$M_B = \chi_{B,0} (H + n_{BB} M_B + n_{AB} M_A) , \qquad (2)$$

where $\chi_{B,0}$ is the paramagnetic susceptibility; C_A is the Curie constant of the *A* atoms; and n_{AA} , n_{BB} , and n_{AB} are molecular-field coefficients which represent exchange interactions inside *A* and *B* sublattices and between these two sublattices. When the magnetization of the *A* atoms is equal to zero, then the total susceptibility is the exchange-enhanced susceptibility

$$\chi_{v} = M_{B}/H = \chi_{B,0}/(1 - n_{BB}\chi_{B,0}) .$$
(3)

From Eqs. (1)-(3) one obtains for the susceptibility of the sample,

$$\chi = \left[C_A + \chi_y (T - EC_A) \right] / (T - \Theta_B) , \qquad (4)$$

with

$$E = n_{AA} - 2n_{AB} {.} {(5)}$$

The magnetic-ordering temperature Θ_B is given by

$$\Theta_B = (n_{AA} + n_{AB}^2 \chi_{\nu}) C_A . \tag{6}$$

In the neighborhood of Θ_B , in the magnetically ordered domains, the spontaneous magnetization of the *B* atoms is proportional to that of the *A* atoms, according to the relation

$$M_B = n_{AB} \chi_y M_A . \tag{7}$$

At low temperature, the magnetization M_B cannot

be considered as proportional to the magnetization M_A , because of the variation of χ_y with the magnetization M_B itself.

II. PARAMAGNETIC PROPERTIES OF A Co2 ALLOYS

Equation (4) for the paramagnetic susceptibility contains two parameters, E and χ_y ; Θ_B is the experimentally determined magnetic-ordering temperature. As a first approximation, these parameters are assumed to be temperature independent; $1/\chi$ as a function of temperature (3) for various ACo_2 alloys is shown in Fig. 1. The variation calculated from Eq. (4) with the E and χ_y parameters, as given in Table I, is shown in the same figure.

We see that two parameters are sufficient to give a good fit to the experimental curves. The χ_y values obtained agree with the room-temperature values of the paramagnetic susceptibility of nonmagnetic alloys YCo₂ (39×10⁻⁴ emu/mole), ¹ ScCo₂ (20×10⁻⁴ emu/mole), ³ and LuCo₂ (30×10⁻⁴ emu/mole). ⁴

In YNi₂, ScNi₂, or LuNi₂, the 3*d* electronic band is full, which give rise to a small susceptibility of the order of 3×10^{-4} emu/mole ^{3,5}; in YFe₂ or LuFe₂ the density of states at the Fermi level is large enough for the Stoner condition for ferromagnetism to be satisfied. In these compounds, iron possesses a magnetic moment of $1.45 \mu_B$.⁶

From Eqs. (5) and (6), we can deduce the values of n_{AA} and n_{AB} (Table I). It is more meaningful, however, to consider exchange-interaction coefficients J_{AA} and J_{AB} , since they are not spin depen-

FIG. 1. Thermal variation of the inverse paramagnetic susceptibility of various ACo_2 alloys. Full curves are theoretical (see text). Data points are taken from Bloch *et al.* (Ref. 4).

TABLE I. Magnetic-ordering temperature, enhanced paramagnetic susceptibility, and main exchange-interaction coefficients of ACo_2 alloys.

| | $\Theta_B(K)$ | χ_y (10 ⁻⁴ emu/mole) | E | J_{AA} | – J _{AB} |
|-------------------|---------------|--------------------------------------|------|----------|-------------------|
| GdCo ₂ | 395 | 36 | 170 | 60 | - 140 |
| $TbCo_2$ | 240 | 28 | 119 | 58 | - 159 |
| $DyCo_2$ | 150 | 35 | 78.5 | 66 | - 140 |
| HoCo ₂ | 100 | 39 | 60 | 52 | - 140 |
| ErCo ₂ | 60 | 33 | 40 | 66 | -120 |

dent. Their values are given by

$$J_{AB} = g_J n_{AB} / (g_J - 1) \tag{8}$$

and

$$J_{AA} = (g_J)^2 n_{AA} / 2(g_J - 1)^2, \qquad (9)$$

where g_J is the Landé factor associated with the J quantum number of the A rare earth.

The values J_{AA} and J_{AB} thus obtained (Table I) are homogeneous.

III. MAGNETIC-ORDERING TEMPERATURES AND MAGNETIZATION

The magnetic-ordering temperature Θ_B [Eq. (6)] can be considered as the sum of two contributions. One, $n_{AA}C_A$, comes from exchange interactions between the A atoms; the other, $n_{AB}^2C_A\chi_y$, is a con-

tribution from the *B* atoms. The two contributions are approximately equal in ACo_2 alloys. A comparison with the Curie temperature of ANi_2 alloys⁵ indicates that rare-earth-rare-earth interactions are two times more important in ACo_2 than in ANi_2 , although the interatomic distances are almost identical. This indicates that the electrons of the incomplete 3*d* band participate in rare-earth-rareearth exchange interactions.

When the magnetic moment of the transition metal is weak, one can consider its value as given by Eq. (6), which can be written

$$M_B = \frac{1}{2} J_{AB} \chi_y S_A .$$

In agreement with the experimental results, the magnetic moment of the transition metal is a function of the alloyed rare earth. It is equal to zero for YCo_2 , $LuCo_2$, or $ScCo_2$, and has its maximum value for $GdCo_2$.

If we take the values of $J_{AB} = -150$ and $\chi_y = 35 \times 10^{-4}$ (Table I), we obtain for cobalt in GdCo₂ a calculated magnetization at absolute zero of $0.91\mu_B$ compared with the experimental value $1.05\mu_B$; and for Co in PrCo₂, we obtain $0.26\mu_B$ compared with the experimental value ⁷ $(0.50 \pm 0.25)\mu_B$.
