(Received 8 May 1995)

Isoelectronic  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions with their ground configuration  $4f^6$  are used in different ternary  $\text{MYX}$  compounds to study the reduction of the Slater parameters  $F_k$  and the spin-orbit coupling parameter  $\zeta_{4f}$ , commonly referred to as the nephelauxetic effect. At first, a simulation of the  $4f^6$  energy levels in the intermediate coupling scheme with the two parameters  $F_2$  and  $\zeta_{4f}$  shows that the set of basis functions must include all the septets ( $^7L_J$ ) and all the quintets ( $^5L_J$ ), as well as some triplets ( $^3P_J$ ,  $^3D_J$ , and  $^3F_J$ ) or singlets ( $^1S_J$ ,  $^1P_J$ , and  $^1D_J$ ) to reproduce the energy level scheme accurately, whereby a strong effect of the triplets and singlets on the  $^5D_J$  multiplets is most prominent. With structural parameters of different host materials at ambient and elevated pressures, different distance dependences of the parameters  $F_2$  and  $\zeta_{4f}$  for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  are derived from the ambient-pressure and high-pressure energy-level schemes, demonstrating a breakdown of the nephelauxetic series. Only a combination of at least two microscopic covalency mechanisms, central-field covalency (CFC) and symmetry-restricted covalency (SRC), allows for a description without contradictions. Thereby the CFC contribution is dominant for the small  $\text{Eu}^{3+}$  ion, whereas the SRC is more dominant for the larger  $\text{Sm}^{2+}$  ion. Finally, *ab initio* calculations of Coulomb integrals are used to evaluate the Slater parameters  $F_k$  of  $\text{Sm}^{2+}$  within the SRC model and close agreement of these results with the experimental data is then obtained.

### I. INTRODUCTION

When a lanthanide ion is incorporated into a host crystal, the so-called crystal field (CF) results in two effects, which are the CF splittings and the centroid shifts of all the free-ion multiplets. The centroid shifts are ascribed to reductions of the Slater parameters  $F_k$  and the spin-orbit coupling parameter  $\zeta_{4f}$  for the lanthanide ion in the host crystal with respect to their free-ion values  $F_k^0$  and  $\zeta_{4f}^0$  and this observation is usually referred to as the nephelauxetic effect.

Systematic considerations of the contributions of different ligands to the CF splittings and the reductions in Slater parameters for  $3d$  ions resulted in two different series, respectively, the spectrochemical and nephelauxetic series. The spectrochemical series for the strength of CF splittings shows the following order:<sup>1</sup>

$$\text{free ion} < \text{I}^- < \text{Br}^- < \text{Cl}^- < \text{S}^{2-} < \text{F}^- < \text{O}^{2-},$$

whereas the nephelauxetic series for the centroid shifts is given<sup>2</sup> as

$$\text{free ion} < \text{F}^- < \text{O}^{2-} < \text{Cl}^- < \text{Br}^- < \text{I}^- \approx \text{S}^{2-}$$

and shows thus a strong anticorrelation with respect to the spectrochemical series. Newman<sup>3</sup> has pointed out that also  $4f$  ion systems seem to follow these two series in most cases, and the large number of the CF studies on lanthanide ions in different hosts shows a strong positive correlation of the strength of overlap and covalency contributions from the crystal field. Correspondingly, various models have been proposed to explain the nephelauxetic effects either by “microscopic covalency”<sup>4</sup> or “macroscopic dielectric”<sup>5</sup> effects.

Thereby, the reduction of the free-ion parameters is usually ascribed to a  $4f$  electron cloud expansion of lanthanide

ions in the crystals. This expansion is modeled by two different mechanisms. Considerations of a spherically symmetric penetration from the ligand electrons are usually referred to as the central-field covalency (CFC) model and this model correlates both free-ion parameters  $F_k$  and  $\zeta_{4f}$  directly with an effective nuclear charge  $Z_{\text{eff}}$  of the lanthanide ions:  $F_k \sim Z_{\text{eff}}$  and  $\zeta_{4f} \sim Z_{\text{eff}}^3$ .<sup>6</sup> On the other hand, the symmetry-restricted covalency (SRC)<sup>7</sup> model describes the symmetry-dependent admixture of  $4f$  orbitals ( $\varphi_m$ ) with neighboring ligand orbitals ( $\chi_\tau$ ). Within a first approximation the modified  $4f$  orbitals are simply normalized as  $\mathcal{N}_m \varphi_m$ , so that the free-ion parameters of lanthanide ions in the crystal are obtained as  $F_k \approx \mathcal{N}^4 F_k^0$  and  $\zeta_{4f} \approx \mathcal{N}^2 \zeta_{4f}^0$ , and the renormalization constants  $\mathcal{N}_m$  are usually treated as empirical parameters.

In the macroscopic dielectric model the host crystal is considered as a dielectric continuum, which reduces the Coulomb interaction between  $4f$  electrons of lanthanide ions. According to this model, the reduction of the Slater parameters is given as  $\Delta F_k \sim R_S^{-(2k+1)}$ , where  $R_S$  is a suitably selected value for the ionic radius of the lanthanide ion.

Recent high-pressure studies<sup>8,9</sup> demonstrated clearly that the relative decrease of the spin-orbit coupling parameter is much smaller than the variation of the Slater parameters. Obviously, the CFC model cannot explain this variation. The dielectric model, on the other hand, involves large uncertainties in the choice of the radius  $R_S$ , limiting its application. However, the predictions of the SRC model are at least qualitatively supported by the high-pressure results, but an earlier *ab initio* calculation<sup>10</sup> for  $\text{Pr}^{3+}$  in  $\text{PrCl}_3$  predicted that these covalency contributions are an order of magnitude too small to account for the reduction of the Slater parameters.

By the use of all the available data for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions in different ternary  $\text{MYX}$  host materials at ambient pressure together with recent high-pressure results, the present

study attempts to resolve these discrepancies, and it is shown that the combination of the two covalency mechanisms leads to quantitatively correct results.

## II. REPRESENTATION OF FREE-ION ENERGY LEVELS

The electronic ground state of the isoelectronic  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions is represented by a  $4f^6$  configuration. The Coulomb interaction ( $H_C$ ) splits this configuration into 119  $2S+1L$  spectral terms and the spin-orbit coupling ( $H_{s.o.}$ ) produces 295  $2S+1L_J$  multiplets. The calculation of energy levels proceeds by a diagonalization of the free-ion Hamiltonian  $H_{FI}$ ,

$$\begin{aligned} \langle |H_{FI}| \rangle &= \langle |H_C| \rangle + \langle |H_{s.o.}| \rangle \\ &= \sum_k f^k F_k + \zeta_{4f} \left\langle \left| \sum_i s_i \cdot l_i \right| \right\rangle, \end{aligned} \quad (1)$$

with the use of a set of basis functions, where the  $f^k$  depend only on the angular parts of the electronic wave functions and are calculated therefore exactly.  $s_i$  and  $l_i$  represent the spin and orbital angular momentum of the  $i$ th  $4f$  electron. The parameters  $F_2$ ,  $F_4$ ,  $F_6$ , and  $\zeta_{4f}$  are treated as free parameters to be determined from the experimentally observed energy levels. Since the Coulomb and spin-orbit interactions are of about equal magnitude for  $4f$  electron systems, the intermediate coupling scheme must be applied in the evaluation of the eigenvalues for Eq. (1).

In addition to these two most important interactions for the determination of the energy levels, there are some higher-order interactions, as, for example, the two- and three-body configuration interactions and the spin-spin interactions with contributions to the energy levels typically less than  $100 \text{ cm}^{-1}$ .

Furthermore, one can take into account that the ratios of the Slater parameters,  $F_4/F_2$  and  $F_6/F_2$ , for all the lanthanide ions are very close to their hydrogenic values. With these fixed ratios, the energy levels depend then only on the two parameters  $F_2$  and  $\zeta_{4f}$ .

It is well known that the multiplets for the  $4f^6$  configuration consist of 7 septets, 74 quintets, 168 triplets, and 46 singlets. However, for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions in different hosts only  ${}^7F_J$  and  ${}^5D_J$  multiplets are usually observed by spectroscopic measurements. Thus, the set of basis functions for the 295 multiplets must be truncated in the fit of the considerably smaller experimental data sets. In the present work, three different basis sets are used to estimate the effects from the truncation on the multiplets of  ${}^7F_J$  and  ${}^5D_J$ .

At first, only the septets and quintets are selected as basis set 1. In order to study the contributions of the triplets and singlets to the  ${}^7F_J$  and  ${}^5D_J$  multiplets, the basis set 2 includes in addition 18  ${}^3P_J$ , 15  ${}^3D_J$ , and 27  ${}^3F_J$  triplets, and the basis set 3 involves furthermore 4  ${}^1S_J$ , one  ${}^1P_J$ , and 6  ${}^1D_J$  singlets. The results for the  ${}^7F_J$  and  ${}^5D_J$  multiplets are then schematically illustrated in Fig. 1.

Since the values of  $\zeta_{4f}/F_2$  for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions range typically from 3 to 4, the singlets have a distinct effect on the energy position of the  ${}^5D_0$  multiplet but only a minor influence on the other multiplets. As shown in Fig. 1, the triplet contributions to the  ${}^5D_J$  multiplets are quite important. As an

FIG. 1. Variation of the  ${}^5D_J$  and  ${}^7F_J$  multiplets of the  $4f^6$  configuration as a function of  $\zeta_{4f}/F_2$ , calculated with different basis sets discussed in the text.

example, the decomposition of the free-ion wave functions for the multiplets  ${}^7F_0$  and  ${}^5D_0$  are given here for  $\zeta_{4f}/F_2 = 3.5$ :

$$|{}^7F_0\rangle \approx 92.8\%|{}^7F\rangle + 6.9\%|{}^5D\rangle + 0.3\%|{}^3P\rangle$$

and

$$|{}^5D_0\rangle \approx 79\%|{}^5D\rangle + 14\%|{}^3P\rangle + 6\%|{}^7F\rangle + 1\%|{}^1S\rangle.$$

This decomposition shows that the ground multiplet  ${}^7F_0$  is only marginally affected by the other multiplets and follows thus a  $LS$  coupling scheme, because all the perturbing states are just too far away. However, the  ${}^5D_J$  multiplets are not only strongly affected by the triplets but also weakly by the singlets with a breakdown of the  $LS$  coupling scheme in this case. This wave function admixture explains also the observation of the “forbidden” transition  ${}^5D_0 \leftrightarrow {}^7F_0$  for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  in many different hosts.

Finally, one has to estimate the contributions from the configuration interactions. If the most important term of the two-body configuration interactions,  $\alpha L(L+1)$  introduced by Trees,<sup>11</sup> is taken into account, this leads to a change of  $\sim 0.7\%$  for  $F_2$  and  $\sim 0.15\%$  for  $\zeta_{4f}$ , estimated here with  $\zeta_{4f}/F_2 = 3.5$  and  $\alpha/F_2 \approx 0.05$  of  $\text{Eu}^{3+}:\text{LaCl}_3$ .<sup>12</sup>

## III. EXPERIMENTAL RESULTS FOR THE FREE-ION PARAMETERS

Experimental data on multiplets for the evaluation of the free-ion parameters  $F_2$  and  $\zeta_{4f}$  are available for  $\text{Sm}^{2+}:\text{MFCI}$  ( $M = \text{Ba}, \text{Sr}, \text{and Ca}$ ),  $\text{Eu}^{3+}:\text{LOX}$  ( $L = \text{La}, \text{Gd}, \text{or Y}$  and  $X = \text{Cl}, \text{Br}, \text{or I}$ ),<sup>13,14</sup> and  $\text{Eu}^{3+}:\text{L}_2\text{O}_2\text{S}$  ( $L =$

FIG. 2. Variation of the  ${}^5D_0$  multiplets for  $\text{Sm}^{2+}:\text{MFCI}$  under pressure. The data for  $\text{Sm}^{2+}:\text{SrFCl}$  and for  $\text{Sm}^{2+}:\text{CaFCl}$  are shifted with respect to  $\text{Sm}^{2+}:\text{BaFCl}$  by pressures of 3 GPa and 6.7 GPa, respectively.

La, Gd, Y, and Lu) (Ref. 15) at ambient pressure as well as for  $\text{Eu}^{3+}:\text{LaOCl}$  (Ref. 16) and  $\text{Eu}^{3+}:\text{LaOBr}$  (Ref. 17) at room temperature under pressures up to 13 GPa and for  $\text{Sm}^{2+}:\text{MFCI}$  at 20 K under pressures up to 8 GPa. While all the results for  ${}^7F_{0-6}$  multiplets of  $\text{Sm}^{2+}:\text{MFCI}$  were reported in previous studies,<sup>18-20</sup> additional information on three  ${}^5D_J$  multiplets,  ${}^5D_{0-2}$ , was obtained in this study with the result that the rates of pressure-induced shifts for their centroids have the same values of  $-21 \text{ cm}^{-1}/\text{GPa}$ ,  $-24 \text{ cm}^{-1}/\text{GPa}$ , and  $-29 \text{ cm}^{-1}/\text{GPa}$ , respectively, in the three different hosts. As an example, the variation of  ${}^5D_0$  for  $\text{Sm}^{2+}:\text{MFCI}$  under pressure is shown in Fig. 2, where the data for  $\text{Sm}^{2+}:\text{SrFCl}$  and  $\text{Sm}^{2+}:\text{CaFCl}$  are shifted with respect to  $\text{Sm}^{2+}:\text{BaFCl}$  by pressures of 3 GPa and 6.7 GPa, respectively. The same behavior is noticed also for  ${}^5D_1$  and  ${}^5D_2$ .

The parameters  $F_2$  and  $\zeta_{4f}$  are then obtained by least squares fitting with respect to the observed multiplet centroids. In the cases where the complete CF levels of some multiplets could not be observed experimentally to determine their centroids, the missing CF levels were calculated first by the use of a CF fitting, including also  $J$  mixing effects, and these missing values for the CF levels of the multiplets are then added to the experimental values in the final determination of these centroids.

#### A. Free-ion parameters at ambient pressure

A hydrogenic approximation for the set of basis functions in Eq. (1) results by the use of a least squares fitting procedure in the values of the parameters  $F_2$  and  $\zeta_{4f}$  for  $\text{Sm}^{2+}$  ions given in Table I, which shows a remarkably good agree-

TABLE I. Free-ion parameters  $F_2$  and  $\zeta_{4f}$  (in  $\text{cm}^{-1}$ ) for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  in different hosts at ambient pressure with standard deviations in parentheses. The numbers of multiplets used in the fits are 10 for  $\text{Sm}^{2+}$ , 8 for  $\text{Eu}^{3+}:\text{LOX}$ , and 9 for  $\text{Eu}^{3+}:\text{Lu}_2\text{O}_2\text{S}$ .  $\sigma$  ( $\text{cm}^{-1}$ ) denotes the standard deviations between observed and calculated energy levels. The experimental data for the multiplets of  $\text{Eu}^{3+}$  are taken from Refs. 13, 14, and 15, respectively.

| Sample   | $F_2$    | $\zeta_{4f}$ | $\sigma$ |
|--|----------|--------------|----------|
| $\text{Sm}^{2+}:\text{BaFCl}$                  | 332.0(2) | 1058(2)      | 13.0     |
| $\text{Sm}^{2+}:\text{SrFCl}$                  | 330.7(2) | 1057(2)      | 10.0     |
| $\text{Sm}^{2+}:\text{CaFCl}$                  | 328.8(1) | 1055(1)      | 6.7      |
| $\text{Eu}^{3+}:\text{LaOCl}$                  | 384.3(3) | 1348(3)      | 15.9     |
| $\text{Eu}^{3+}:\text{GdOCl}$                  | 383.0(2) | 1336(2)      | 8.1      |
| $\text{Eu}^{3+}:\text{YOCl}$                   | 382.7(2) | 1334(2)      | 10.4     |
| $\text{Eu}^{3+}:\text{LaOBr}$                  | 384.8(3) | 1356(4)      | 17.8     |
| $\text{Eu}^{3+}:\text{GdOBr}$                  | 383.2(2) | 1339(2)      | 8.1      |
| $\text{Eu}^{3+}:\text{YOBr}$                   | 382.9(2) | 1337(2)      | 7.4      |
| $\text{Eu}^{3+}:\text{LaOI}$                   | 384.5(3) | 1353(4)      | 17.2     |
| $\text{Eu}^{3+}:\text{La}_2\text{O}_2\text{S}$ | 382.3(3) | 1327(4)      | 17.5     |
| $\text{Eu}^{3+}:\text{Gd}_2\text{O}_2\text{S}$ | 381.6(3) | 1325(4)      | 15.7     |
| $\text{Eu}^{3+}:\text{Y}_2\text{O}_2\text{S}$  | 381.4(2) | 1325(3)      | 15.3     |
| $\text{Eu}^{3+}:\text{Lu}_2\text{O}_2\text{S}$ | 381.1(2) | 1324(3)      | 15.0     |

ment between fitted and experimental energy levels by standard deviations  $\sigma$  around  $10 \text{ cm}^{-1}$ .

For  $\text{Eu}^{3+}$  ions the fitting in the hydrogenic approximation leads also to a reasonable agreement with the experimental data, however, with slightly larger standard deviations of  $\bar{\sigma} \sim 20 \text{ cm}^{-1}$  in comparison with the cases of  $\text{Sm}^{2+}$  ions with  $\bar{\sigma} = 10 \text{ cm}^{-1}$ . These larger deviations are possibly due to the hydrogenic approximation. In fact, it has been noticed previously in an evaluation of the free-ion parameters for all the trivalent lanthanide ions in  $\text{LaCl}_3$  that the average values for the ratios  $F_4/F_2=0.148(4)$  and  $F_6/F_2=0.016(1)$  (Ref. 12) show close agreement with the hydrogenic value of 0.0151 in the latter case, whereas the hydrogenic value of 0.138 for  $F_4/F_2$  deviates slightly from the best fitted value. Similarly, it is noticed in the present fits that the use of the ‘‘experimental’’  $F_4/F_2$  ratio from  $\text{LaCl}_3$  improves also the present results. For example, the deviation of  $\sigma=21.4 \text{ cm}^{-1}$  for  $\text{Eu}^{3+}:\text{GdOCl}$  is reduced to  $\sigma=8.1 \text{ cm}^{-1}$  by the use of the ‘‘experimental’’ ratio  $F_4/F_2=0.148$ , and therefore, this ratio is used in the fitting procedure for the evaluation of the parameters  $F_2$  and  $\zeta_{4f}$  for  $\text{Eu}^{3+}$  presented in Table I. Corresponding observed and calculated energy levels for  $\text{Sm}^{2+}:\text{SrFCl}$ ,  $\text{Eu}^{3+}:\text{GdOCl}$ , and  $\text{Eu}^{3+}:\text{Gd}_2\text{O}_2\text{S}$  are listed in Table II just as typical examples.

The results in Tables I and II indicate clearly that the two-parameter set can reasonably describe the energy-level schemes for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions in their  $4f^6$  configurations. Previously, Ofelt<sup>21</sup> has studied these  $4f^6$  configuration systems, but without taking into account the influence of the singlets with the results  $F_2=330 \text{ cm}^{-1}$  and  $\zeta_{4f}=1050 \text{ cm}^{-1}$  for  $\text{Sm}^{2+}$  and  $F_2=401 \text{ cm}^{-1}$  and  $\zeta_{4f}=1320 \text{ cm}^{-1}$  for  $\text{Eu}^{3+}$ . These data give reductions for  $F_2$  and  $\zeta_{4f}$  of  $-18\%$  and  $-20\%$  from  $\text{Eu}^{3+}$  to  $\text{Sm}^{2+}$ , whereas the present study gives average reductions of  $-14(1)\%$  for  $F_2$  and  $-21(1)\%$  for  $\zeta_{4f}$  from the data in Table I.

TABLE II. Observed and calculated energy levels ( $\text{cm}^{-1}$ ) for  $\text{Sm}^{2+}:\text{SrFCl}$ ,  $\text{Eu}^{3+}:\text{GdOCl}$ , and  $\text{Eu}^{3+}:\text{Gd}_2\text{O}_2\text{S}$  at ambient pressure. Only for the comparison with the calculated values also the estimated values for incomplete CF levels are given in parentheses.

| Multiplet | $\text{Sm}^{2+}:\text{SrFCl}$ |                  | $\text{Eu}^{3+}:\text{GdOCl}$ |                  | $\text{Eu}^{3+}:\text{Gd}_2\text{O}_2\text{S}$ |                  |

At this point, some comments on the literature data seem to be appropriate.

(i) For  $\text{Sm}^{2+}$  in  $M\text{FCl}$  the value for  $\zeta_{4f}$  was deduced only from the 7  ${}^7F_J$  multiplets with the results of  $1154 \text{ cm}^{-1}$  for  $\text{Sm}^{2+}:\text{BaFCl}$  (Ref. 22) and  $1361 \text{ cm}^{-1}$  for  $\text{Sm}^{2+}:\text{SrFCl}$ .<sup>23</sup> These larger values in comparison with the present results can be traced back to the neglect of the intermediate coupling. If only the  ${}^7F_J$  multiplets would be used also here, a value of  $\zeta_{4f} = 1056 \text{ cm}^{-1}$  would be obtained for  $\text{Sm}^{2+}:\text{SrFCl}$ . This observation illustrates that the value for  $\zeta_{4f}$  is clearly affected by the intermediate coupling, even if the wave functions for the  ${}^7F_J$  multiplets are dominated by more than 90% by the contributions from the  $LS$  components.

(ii) Attempts by Hölsä and Porcher<sup>13,14</sup> to fit the observed energy levels of  $\text{Eu}^{3+}:\text{LOX}$  resulted in standard deviations  $\sigma$  from 29 to 39  $\text{cm}^{-1}$  for  $\text{LOCl}$  and from 28 to 45  $\text{cm}^{-1}$  for  $\text{LOBr}$  and did not show any systematic variation of either  $F_k$  and  $\zeta_{4f}$  within this class of isostructural crystals. A new attempt<sup>24</sup> with smaller basis sets gave no improvements. One can thus conclude that not only the intermediate coupling but also extended basis sets are needed to describe in this case the  $4f^6$  configuration accurately.

### B. Pressure dependence of free-ion parameters

When the same procedures are used to derive the pressure dependence of the parameters  $F_2$  and  $\zeta_{4f}$  from the high-pressure data of  $\text{Sm}^{2+}:\text{MFCl}$  up to 8 GPa, of  $\text{Eu}^{3+}:\text{LaOCl}$ , and  $\text{Eu}^{3+}:\text{LaOBr}$  up to 13 GPa, one finds that the standard deviations decrease with increasing pressure almost by a factor of 2 in all the cases except for  $\text{Sm}^{2+}:\text{CaFCl}$ . This overall decrease in  $\sigma$  results mainly from better fits of the  ${}^5D_J$  multiplets.

A simple explanation of this effect cannot be found in the literature. Some hints are given, however, by the observation that higher-order interactions for instance in the form of correlation crystal fields<sup>25</sup> (CCF's) affect the CF splittings of the  ${}^5D_J$  multiplets for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$ ,<sup>18</sup> in a similar way in the

FIG. 3. Variation of the parameter  $F_2$  for  $\text{Sm}^{2+}:\text{MFCl}$  under pressure. The data for  $\text{Sm}^{2+}:\text{SrFCl}$  and for  $\text{Sm}^{2+}:\text{CaFCl}$  are shifted with respect to  $\text{Sm}^{2+}:\text{BaFCl}$  by pressures of 3 GPa and 6.7 GPa, respectively.

case of  ${}^2H_{11/2}$  for  $\text{Nd}^{3+}$ .<sup>26</sup> High-pressure studies on  $\text{Nd}^{3+}:\text{LaCl}_3$  (Ref. 27) lead to the interesting result that the influence of the CCF effects on the  ${}^2H_{11/2}$  splittings shows a strong decrease under pressure, and a similar mechanism may apply also in the present case.

The variations of  $F_2$  and  $\zeta_{4f}$  under pressure are illustrated in Figs. 3–6 with the same pressure shifts of the frames applied already in Fig. 2 and with a pressure shift of 3.3 GPa

FIG. 4. Variation of the parameter  $\zeta_{4f}$  for  $\text{Sm}^{2+}:\text{MFCl}$  under pressure. The data for  $\text{Sm}^{2+}:\text{SrFCl}$  and for  $\text{Sm}^{2+}:\text{CaFCl}$  are shifted with respect to  $\text{Sm}^{2+}:\text{BaFCl}$  by pressures of 3 GPa and 6.7 GPa, respectively.

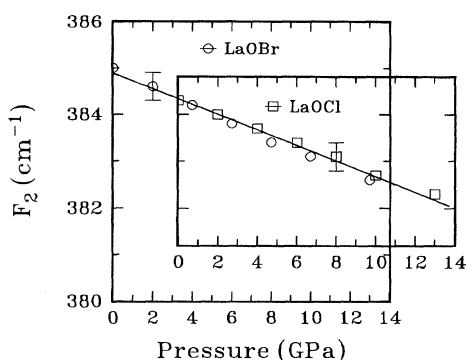

FIG. 5. Variation of the parameter  $F_2$  for  $\text{Eu}^{3+}:\text{LaOCl}$  and  $\text{Eu}^{3+}:\text{LaOBr}$  under pressure. The data for  $\text{Eu}^{3+}:\text{LaOCl}$  are shifted with respect to  $\text{Eu}^{3+}:\text{LaOBr}$  by a pressure of 3.3 GPa.

for  $\text{Eu}^{3+}:\text{LaOCl}$  with respect to  $\text{Eu}^{3+}:\text{LaOBr}$ . In all these cases, a linear pressure dependence is observed with slopes for  $F_2$  of  $-0.482(6) \text{ cm}^{-1}/\text{GPa}$  for  $\text{Sm}^{2+}$  and of  $-0.167(6) \text{ cm}^{-1}/\text{GPa}$  for  $\text{Eu}^{3+}$ , and for  $\zeta_{4f}$  of  $-0.51(3) \text{ cm}^{-1}/\text{GPa}$  for  $\text{Sm}^{2+}$  and of  $-1.23(6) \text{ cm}^{-1}/\text{GPa}$  for  $\text{Eu}^{3+}$ .

Evidently, the pressure-induced change of the Slater parameter  $F_2$  for  $\text{Sm}^{2+}$  is about 3 times as strong as for  $\text{Eu}^{3+}$ , whereas the spin-orbit parameter  $\zeta_{4f}$  of  $\text{Sm}^{2+}$  shows only about half the shift of  $\text{Eu}^{3+}$ .

FIG. 6. Variation of the parameter  $\zeta_{4f}$  for  $\text{Eu}^{3+}:\text{LaOCl}$  and  $\text{Eu}^{3+}:\text{LaOBr}$  under pressure. The data for  $\text{Eu}^{3+}:\text{LaOCl}$  are shifted with respect to  $\text{Eu}^{3+}:\text{LaOBr}$  by a pressure of 3.3 GPa.

## IV. DISCUSSIONS

### A. Distance dependence of free-ion parameters

A deeper understanding of the nephelauxetic effects on  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions not only in different hosts at ambient conditions but also under pressure requires an analysis on the basis of interionic distances.

Ternary  $\text{MYX}$  compounds of the type  $\text{MFX}$ ,  $\text{LOX}$ , and  $\text{L}_2\text{O}_2\text{S}$  were considered as host materials for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions, whereby both the  $\text{MFX}$  and  $\text{LOX}$  compounds belong to a tetragonal  $\text{PbFCl}$ -type structure and the  $\text{L}_2\text{O}_2\text{S}$  compounds to a hexagonal structure. In the  $\text{PbFCl}$ -type structure,  $M$  or  $L$  cations are coordinated by nine ligands, four  $F$  or  $O$  anions at  $R_1$ , four  $X$  anions at  $R_2$ , and an extra  $X$  anion located at  $R_3$  on the crystallographic axis  $c$ . In the hexagonal structure of  $\text{L}_2\text{O}_2\text{S}$ ,  $L$  cations are surrounded by three  $S$  anions at  $R_1$ , three  $O$  anions at  $R_2$ , and an extra  $O$  anion at  $R_3$ . The interionic distances  $R_i$  and the coordination numbers  $n_i$  of the first-nearest-neighboring ligands are given in Table III together with an average distance for the coordination polyhedra  $\bar{R} = \sum n_i R_i / \sum n_i$ .

The dependence of the parameters  $F_2$  and  $\zeta_{4f}$  on  $\bar{R}$  is represented in Figs. 7 and 8, where the effects of pressure for  $\text{Sm}^{2+}:\text{MFCl}$  and  $\text{Eu}^{3+}:\text{LaOCl}$  are shown by solid arrows. The variations of the distances under pressure for  $\text{MFCl}$  hosts are given in the literature.<sup>18,19</sup> For  $\text{LaOCl}$ , reasonable estimates could be made by assuming constant values for the atom position parameters  $z_{\text{La}}$  and  $z_{\text{Cl}}$  under pressure together with experimental data for the host lattice parameters  $a$  and  $c$ .<sup>35</sup>

As shown in Figs. 7 and 8,  $F_2$  and  $\zeta_{4f}$  decrease almost linearly with decreasing interionic distances; however, the pressure-induced decrease in  $F_2$  and  $\zeta_{4f}$  shows significant deviations from the host-induced shifts. To a large extent, these deviations are accounted for by local distortions around the lanthanide ions in the different host crystals due to the different ionic size of the host lattice cations with respect to the impurity ions. For example, the  $\text{Sm}^{2+}$  ions in the three different  $\text{MFCl}$  hosts have negligible distortions in  $\text{SrFCl}$  due to the same ionic size of  $\text{Sm}^{2+}$  and  $\text{Sr}^{2+}$ ; however, negative distortions are expected in  $\text{BaFCl}$  due to the larger ionic size of  $\text{Ba}^{2+}$  with respect to  $\text{Sm}^{2+}$ , and positive distortions must be taken into account in  $\text{CaFCl}$  due to the smaller ionic size of  $\text{Ca}^{2+}$ . As shown in Fig. 2, the  $^5D_J$ -multiplet centroid positions, expanded by  $-3 \text{ GPa}$  for  $\text{Sm}^{2+}$  in  $\text{BaFCl}$  and contracted by  $3.7 \text{ GPa}$  for  $\text{Sm}^{2+}$  in  $\text{CaFCl}$  with respect to  $\text{Sm}^{2+}$  in  $\text{SrFCl}$ , coincide with each other at ambient conditions and show then under pressure also the same shifts. If one assumes that all the multiplet centroid shifts of  $\text{Sm}^{2+}$  in different isostructural crystals are energetically similar, the local structures around  $\text{Sm}^{2+}$  in these crystals result in identical shifts. The same approach leads also to a consistent picture for both  $F_2$  and  $\zeta_{4f}$  of  $\text{Sm}^{2+}:\text{MFCl}$  as shown in Figs. 3 and 4. In any case, one obtains direct informations on local structures around the lanthanide ions in different isostructural crystals, when one compares the ambient-pressure data with high pressure results.

Furthermore, Figs. 7 and 8 show very clearly that the decrease in both  $F_2$  and  $\zeta_{4f}$  for  $\text{Eu}^{3+}$  in the host series  $\text{LaOI-LaOBr-LaOCl}$ ,  $\text{GdOBr-GdOCl}$ , and  $\text{YOBr-YOCl}$  is reversed with respect to the nephelauxetic series of ligands. Also in

TABLE III. Interionic distances  $R$  (pm) of the nearest ligands.  $\bar{R}$  (pm) represents an average distance (see text) and  $n$  denotes the number of ligands in the coordination polyhedron. The values of  $\bar{R}$  marked by an asterisk are calculated for the eight nearest neighbors only, because the contribution of the ninth ion is relatively small in the case of LaOI, GdOBr, and YOBr.

|                                  |     |        |          |                |      |

the comparison of  $\text{Eu}^{3+}:\text{La}_2\text{O}_2\text{S}$  with  $\text{Eu}^{3+}:\text{LaOI}$ , the nephelauxetic series breaks down, because the contributions of  $\text{S}^{2-}$  and  $\text{I}^-$  ligands should be similar in magnitude according to this series. For example, the La-O distances are approximately equal in the cases of  $\text{La}_2\text{O}_2\text{S}$  and LaOI crystals, so that  $\text{O}^{2-}$  ligands should contribute the same amount to the reduction of  $F_2$  and  $\zeta_{4f}$  in both cases. Thus, the surprisingly

FIG. 7. Variations of the Slater parameter  $F_2$  ( $\text{cm}^{-1}$ ) for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  in different host crystals as a function of  $\bar{R}$  (pm). Arrows with the solid circles denote the variations under pressure.

large difference in  $F_2$  and  $\zeta_{4f}$  between  $\text{Eu}^{3+}:\text{La}_2\text{O}_2\text{S}$  and  $\text{Eu}^{3+}:\text{LaOI}$  must result from the difference of the  $\text{S}^{2-}$  and  $\text{I}^-$  ligands.

For  $\text{Sm}^{2+}$  in different MFX compounds, one has no experimental results for  $\text{Sm}^{2+}$  in MFB or MFI to confirm this same effect. However, preliminary measurements on  $\text{Sm}^{2+}:\text{BaFBr}$  at ambient pressure and 20 K were performed in the present study to determine the positions of the  $^5D_J$  multiplets. The observed values of  $14\,551\text{ cm}^{-1}$  for  $^5D_0$  and  $15\,890\text{ cm}^{-1}$  for  $^5D_1$  are both larger by 21 and  $22\text{ cm}^{-1}$  than the corresponding values of  $\text{Sm}^{2+}:\text{BaFCl}$  and from the systematic result shown in Fig. 2 a larger Slater parameter

FIG. 8. Variations of the spin-orbit parameter  $\zeta_{4f}$  ( $\text{cm}^{-1}$ ) for  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  in different host crystals as a function of  $\bar{R}$  (pm). Arrows with the solid circles denote the variations under pressure.

$F_2$  for  $\text{Sm}^{2+}:\text{BaFBr}$  is then derived also with respect to  $\text{Sm}^{2+}:\text{BaFCl}$ . Together with the known structural parameters of  $\text{BaFBr}$ ,<sup>29</sup> which results in  $\bar{R}=307.2$  pm, the larger value of  $F_2$  for  $\text{Sm}^{2+}:\text{BaFBr}$  fits then also very well to the distance dependence of  $F_2$  in Fig. 7, but violates the nephelauxetic series.

However, it is not clear whether the two different types of ligand ions in the present series of ternary  $MYX$  compounds could also result in contributions from ligand-ligand interactions which could equally well lead to a counterbalance of the different ligand types with serious deviations from the nephelauxetic series.

### B. Covalency models

The  $4f$  radial wave functions  $R_{4f}(r)$  of free lanthanide ions are commonly described by a linear combination of a few Slater orbitals.<sup>36</sup> Within the two different covalency models, the open-shell  $4f$  orbitals expand, when a lanthanide ion is embedded into a host. In the CFC model, this expansion is caused by a spherically symmetric penetration of ligand electrons into the  $4f$  orbitals, and this expansion is then described in first order by an "expansion parameter"  $\kappa$  in the radial wave function

$$R_{4f}(r) = \kappa^{9/2} \sum_i C_i r^3 e^{-\kappa Z_i r}, \quad (2)$$

where  $C_i$  and  $Z_i$  represent regular expansion coefficients and orbital exponents, respectively. In this approximation, the Slater parameters and the spin-orbit coupling parameter are related to the corresponding free-ion parameters  $F_2^0$  and  $\zeta_{4f}^0$  just by this one parameter  $\kappa$ :

$$F_k = \kappa F_k^0 \quad \text{and} \quad \zeta_{4f} = \kappa^3 \zeta_{4f}^0. \quad (3)$$

In other words, such an isotropic ligand-electron penetration screens the effective nuclear charge  $Z_{\text{eff}}$  of the lanthanide ion which results in the expansion of the  $4f$  orbitals and one expects then for lanthanides  $F_k \sim Z_{\text{eff}}$  and  $\zeta_{4f} \sim Z_{\text{eff}}^3$ , which corresponds to Eq. (3) with  $\kappa = Z_{\text{eff}}/Z_{\text{eff}}^0$ .

Within the SRC mechanism, on the other hand, the  $4f$  orbitals  $\varphi_m$  are modified by the symmetry-dependent covalency admixture with the ligand orbitals  $\chi_\tau$  and the molecular orbitals  $\varphi'_\Gamma$  are given by

$$\varphi'_\Gamma = \mathcal{N}'_\Gamma \left( \varphi_\Gamma - \sum_\tau \lambda_{\Gamma\tau} \chi_\tau \right), \quad (4)$$

with

$$\mathcal{N}'_\Gamma = \left( 1 - 2 \sum_\tau \lambda_{\Gamma\tau} S_{\Gamma\tau} + \sum_\tau \lambda_{\Gamma\tau}^2 \right)^{-1/2}, \quad (5)$$

where the  $\lambda_{\Gamma\tau}$ 's represent admixture coefficients, which are simple sums of the overlap integrals  $S_{\Gamma\tau}$  and the conventional covalency parameters  $\gamma_{\Gamma\tau}$ . When this covalency is weak, a good approximation for the modified  $4f$  orbitals  $\varphi'_\Gamma$  in Eq. (4) is given simply by  $\mathcal{N}'_\Gamma \varphi_\Gamma$  with the results for the Slater parameters and the spin-orbit coupling parameter in the forms

$$F_k = \mathcal{N}'^4 F_k^0 \quad \text{and} \quad \zeta_{4f} = \mathcal{N}'^2 \zeta_{4f}^0, \quad (6)$$

where the  $\mathcal{N}'_\Gamma$ 's for all the different orbitals are usually assumed to be approximately equal. The reductions of the free-ion parameters in a crystal are then correlated by Eq. (6), where  $\mathcal{N}'$  can be treated as the one adjustable, empirical parameter.

Usually, either the CFC or SRC mechanism has been used separately to describe the nephelauxetic effect of the lanthanide ions. However, these two kinds of the mechanisms could also act simultaneously and a suitable combination of them may be used most reasonably to describe in general the lanthanide systems. In the simplest way, the radial wave function of Eq. (2) is directly used in Eq. (4), which results then in  $F_k = \mathcal{N}'^4 \kappa F_k^0$  and  $\zeta_{4f} = \mathcal{N}'^2 \kappa^3 \zeta_{4f}^0$ . Correspondingly, their relative reductions can be written as

$$\frac{\Delta F_k}{F_k} = \frac{\Delta \kappa}{\kappa} + 4 \frac{\Delta \mathcal{N}'}{\mathcal{N}'} \quad \text{and} \quad \frac{\Delta \zeta_{4f}}{\zeta_{4f}} = 3 \frac{\Delta \kappa}{\kappa} + 2 \frac{\Delta \mathcal{N}'}{\mathcal{N}'}. \quad (7)$$

From the experimental data given in Figs. 7 and 8 one finds that the variation for  $\text{Eu}^{3+}$  from  $\text{LaOI}$  to  $\text{Lu}_2\text{O}_2\text{S}$  amounts to  $-1.04\%$  for  $F_2$  and  $-2.70\%$  for  $\zeta_{4f}$ , while  $\bar{R}$  changes from 248.4 pm to 294.7 pm. Thereby, the relative reduction of  $\Delta F_2/F_2$  with respect to  $\Delta \zeta_{4f}/\zeta_{4f}$  is almost three times weaker, which would correspond to the prediction of the CFC model. The direct use of Eq. (7) gives for this case  $\Delta \kappa/\kappa = -0.87\%$  and  $\Delta \mathcal{N}'/\mathcal{N}' = -0.04\%$ . This result indicates that the contribution from the CFC to the reduction of  $F_2$  and  $\zeta_{4f}$  dominates in the case of  $\text{Eu}^{3+}$ . Also, in the cases of  $\text{Eu}^{3+}:\text{LaOCl}$  and  $\text{Eu}^{3+}:\text{LaOBr}$  under pressures up to 13 GPa, the variations in  $F_2$  and  $\zeta_{4f}$  by  $-0.56\%$  and  $-1.18\%$ , respectively, deviate only slightly from the CFC model and result in changes for  $\kappa$  of  $-0.36\%$  and  $\mathcal{N}'$  of  $-0.05\%$ . In comparison with ambient-pressure data the contribution of the SRC becomes more significant under pressure in this case.

In the same way, the "chemical shifts" for  $\text{Sm}^{2+}$  in  $\text{MFCl}$  compounds at ambient pressure shown in Figs. 7 and 8 are modeled by  $\Delta \kappa/\kappa = 0.08\%$  and  $\Delta \mathcal{N}'/\mathcal{N}' = -0.28\%$  and the pressure shifts for a pressure range of 8 GPa in these three hosts result just in the same values. This equivalence of chemical and pressure shifts for  $\text{Sm}^{2+}$  in  $\text{MFCl}$  hosts has been discussed already in relation with Figs. 3 and 4.

The small positive value for  $\Delta \kappa/\kappa$  seems not to be significant within the given uncertainty of this analysis and may be considered only as an indication for the overwhelming dominance of the SRC in the case of  $\text{Sm}^{2+}$ .

Thus, one can notice that changes in the CFC or in other words changes in the shielding of the total nuclear charge represent the dominant contribution to the decrease in  $F_2$  and  $\zeta_{4f}$  for the small  $\text{Eu}^{3+}$  ion in different hosts with small contributions only from the SRC or "ligand hybridization," which increases more rapidly in this case with pressure than by chemical shifts, whereas for the larger  $\text{Sm}^{2+}$  ion this "ligand hybridization" seems to explain all the effects.

From this point of view, it is interesting to check whether this SRC model can also predict quantitatively the changes of  $F_2$  and  $\zeta_{4f}$  for  $\text{Sm}^{2+}$  ions in different surroundings with different values for the average distance  $\bar{R}$ .

TABLE IV. Sum values (in units of  $10^{-4}$  a.u.) of the Coulomb integrals  $\text{CI}_1(m_1, m_2)$ ,  $\text{CI}_2(m_1, m_2)$ , and  $\text{CI}_3(m_1, m_2)$  for the systems  $\text{Sm}^{2+}\text{-F}^-$  and  $\text{Sm}^{2+}\text{-Cl}^-$  at interionic distances 4.704 a.u. and 5.906 a.u., respectively, corresponding to an average distance  $\bar{R}=5.372$  a.u.

### C. Quantitative calculations of Slater parameter variations for $\text{Sm}^{2+}$ within the SRC model

The contributions from the orbitals  $\chi_\tau$  ( $\tau=s, p\sigma$ , and  $p\pi$ ) of a ligand to the  $4f$  orbitals  $\varphi_m$  with  $m=0, \pm 1$  of the central  $4f$  ion are represented in the molecular orbital approximation by

$$\varphi'_0 = \mathcal{N}'_0(\varphi_0 - \lambda_{p\sigma}\chi_{p\sigma} - \lambda_s\chi_s),$$

$$\varphi'_1 = \mathcal{N}'_1(\varphi_1 - \lambda_{p\pi}\chi_{p\pi}),$$

$$\varphi'_2 = \varphi_2,$$

$$\varphi'_3 = \varphi_3.$$

With the use of the radial wave functions for  $\text{Sm}^{2+}$ ,  $\text{F}^-$ , and  $\text{Cl}^-$  from the literature,<sup>36-38</sup> an *ab initio* calculation of the diagonal Coulomb interactions ( $\text{CI}$ 's) involves only three covalency corrections  $\text{CI}_1(m_1, m_2)$ ,  $\text{CI}_2(m_1, m_2)$ , and  $\text{CI}_3(m_1, m_2)$  with respect to the unperturbed  $4f$  Coulomb integrals  $\langle \varphi_{m_1}\varphi_{m_2} | r_{12}^{-1} | \varphi_{m_1}\varphi_{m_2} \rangle$ , when only terms in  $\lambda_m$  and  $\lambda_m^2$  are taken into account with

$$\begin{aligned} \text{CI}_1(m_1, m_2) = & \mathcal{N}_{m_1}^2 \mathcal{N}_{m_2}^2 (-2\lambda_{m_1} \langle \chi_{m_1}\varphi_{m_2} | r_{12}^{-1} | \varphi_{m_1}\varphi_{m_2} \rangle \\ & - 2\lambda_{m_2} \langle \chi_{m_2}\varphi_{m_1} | r_{12}^{-1} | \varphi_{m_2}\varphi_{m_1} \rangle), \end{aligned}$$

$$\begin{aligned} \text{CI}_2(m_1, m_2) = & \mathcal{N}_{m_1}^2 \mathcal{N}_{m_2}^2 (\lambda_{m_1}^2 \langle \chi_{m_1}\varphi_{m_2} | r_{12}^{-1} | \chi_{m_1}\varphi_{m_2} \rangle \\ & + \lambda_{m_2}^2 \langle \chi_{m_2}\varphi_{m_1} | r_{12}^{-1} | \chi_{m_2}\varphi_{m_1} \rangle), \end{aligned}$$

$$\text{CI}_3(m_1, m_2) = (\mathcal{N}_{m_1}^2 \mathcal{N}_{m_2}^2 - 1) \langle \varphi_{m_1}\varphi_{m_2} | r_{12}^{-1} | \varphi_{m_1}\varphi_{m_2} \rangle.$$

In addition to the two-center integrals for the ion pairs  $\text{Sm}^{2+}(4f)\text{-F}^-(2s, 2p)$  and  $\text{Sm}^{2+}(4f)\text{-Cl}^-(3s, 3p)$  also the corresponding overlap integrals have to be calculated for the evaluation of the renormalization parameters  $\mathcal{N}$  as given in

TABLE V. Overlap integrals ( $\times 10^{-2}$ ) of  $\text{Eu}^{3+}\text{-O}^{2-}$  and  $\text{Eu}^{3+}\text{-Cl}^-$  ion pairs at different distances  $R$  (a.u.), corresponding to the values of  $\text{LaOCl}$  at ambient pressure and 13 GPa.  $S_\Sigma$  denotes a sum of  $S_s$ ,  $S_{p\sigma}$ , and  $S_{p\pi}$ . The radial wave functions of  $\text{Eu}^{3+}$ ,  $\text{O}^{2-}$ , and  $\text{Cl}^-$  are employed here in Refs. 42, 43, and 38.

|                                | $R$   | $S_s$ | $S_{p\sigma}$ | $S_{p\pi}$ | $S_\Sigma$ |
|--------------------------------|-------|-------|---------------|------------|------------|
| $\text{Eu}^{3+}\text{-O}^{2-}$ | 4.511 | 1.284 | 1.545         | 1.064      | 3.893      |
|                                | 4.405 | 1.434 | 1.672         | 1.184      | 4.290      |
| $\text{Eu}^{3+}\text{-Cl}^-$   | 6.057 | 0.340 | 0.684         | 0.369      | 1.393      |
|                                | 5.907 | 0.401 | 0.762         | 0.423      | 1.586      |
|                                | 5.860 | 0.422 | 0.788         | 0.442      | 1.652      |
|                                | 5.732 | 0.489 | 0.870         | 0.501      | 1.860      |

Eq. (5). With the admixture coefficients  $\lambda$  from the literature<sup>20</sup> and the known interionic distances for  $\text{Sm}^{2+}$  in  $\text{SrFCl}$  at ambient pressure, numerical calculations result in the data given in Table IV. With these results, the reductions  $\delta F_k = F_k - F_k^0$  of the free-ion Slater parameters  $F_k^0$  are calculated first for the two different ligands and then added up according to the given coordination numbers in the evaluation of the total effects for  $\text{Sm}^{2+}:\text{SrFCl}$ :  $\delta F_2 = -2.4 \text{ cm}^{-1}$ ,  $\delta F_4 = -0.65 \text{ cm}^{-1}$ , and  $\delta F_6 = -0.11 \text{ cm}^{-1}$ .

Thereby, one can notice that opposite signs of the contributions from  $\text{CI}_1(m_1, m_2)$  and  $\text{CI}_2(m_1, m_2)$  shown in Table IV lead to a strong cancellation of these terms as noticed previously<sup>10</sup> for the system  $\text{Pr}^{3+}\text{-Cl}^-$ . Due to this cancellation, one finds that the simple replacement of the covalency-modified  $4f$  orbitals  $\varphi'_\Gamma$  by  $\mathcal{N}'_\Gamma \varphi_\Gamma$  results already in a reasonable approximation with typical errors for  $\delta F_2$  of about 20% and the same approximation for the renormalization parameter  $\mathcal{N}$  of the different admixture orbitals leads only to the error less than 0.5%.

Experimental data for  $F_k^0$  of the free ion  $\text{Sm}^{2+}$ , called  $\text{Sm}(\text{III})$ , are not available for a direct comparison with the present calculation; however, the parameters  $F_2$  and  $\zeta_{4f}$  for the free ion  $\text{Sm}(\text{I})$  with a ground electron configuration  $4f^6 6s^2$  have been determined experimentally:<sup>39</sup>  $F_2 = 335.6 \text{ cm}^{-1}$  and  $\zeta_{4f} = 1062 \text{ cm}^{-1}$ . Since the energy levels of the  $4f^n$  core are almost independent of the number of outer  $6s$  electrons in the lanthanide series,<sup>6</sup> one can safely assume that the free-ion parameters for  $\text{Sm}(\text{III})$  have the same values as for  $\text{Sm}(\text{I})$ , and this assumption is further supported by the almost identical energy level schemes for the free ions  $\text{Sm}(\text{III})$  (Ref. 40) and  $\text{Sm}(\text{I})$ .<sup>39</sup> With these results, one obtains a reduction of  $F_2$  for  $\text{Sm}^{2+}$  in  $\text{SrFCl}$  of about  $4.9 \text{ cm}^{-1}$ , whereas the present calculation gives a value of  $2.4 \text{ cm}^{-1}$ , which is considered as good agreement.

The Slater parameters  $F_k$  evaluated by the use of the Hartree-Fock  $4f$  radial wave functions<sup>36</sup> are considerably larger than the observed values for the lanthanide ions, since the Hartree-Fock wave functions are too much contracted due to an omission of configuration interactions, and configuration mixing of the  $4f^n$  configuration with other configurations up to 50% is well known.<sup>41</sup> This discrepancy can be removed, however, by an artificial expansion of the Hartree-Fock  $4f$  radial wave functions to simulate configuration mixing.

In the same way, one can also estimate the contributions of the covalency admixture to the parameter reductions for  $\text{Eu}^{3+}$  ions. For example, Table V gives the overlap integrals  $S_s$ ,  $S_{p\sigma}$ , and  $S_{p\pi}$  of  $\text{Eu}^{3+}-\text{O}^{2-}$  and  $\text{Eu}^{3+}-\text{Cl}^-$  ion pairs for  $\text{Eu}^{3+}:\text{LaOCl}$  at ambient pressure and 13 GPa. In the evaluation of the renormalization constants  $\mathcal{N}$ , one can reasonably assume the ratio between the total admixture coefficient  $\lambda_\Sigma$  and the total overlap integral  $S_\Sigma$  of the  $s$ ,  $p\sigma$ , and  $p\pi$  orbitals  $\lambda_\Sigma/S_\Sigma \approx 2.2$  for  $\text{Eu}^{3+}-\text{O}^{2-}$  and  $\text{Eu}^{3+}-\text{Cl}^-$  ion pairs according to *ab initio* calculations for  $\text{Pr}^{3+}-\text{Cl}^-$  (Ref. 44) and  $\text{Pr}^{3+}-\text{F}^-$  ion-pairs.<sup>45</sup> The change in  $\mathcal{N}$  from all the nine ligand ions under pressures up to 13 GPa is found to amount then to about  $-0.04\%$  which is in very close agreement with the “experimental” value of  $-0.05\%$  derived in the previous section.

## V. CONCLUSIONS

The comparison of “chemically” and pressure-induced changes in the Slater parameter  $F_2$  and in the spin-orbit cou-

pling parameter  $\zeta_{4f}$  for the  $4f$  electrons of  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  ions in different host materials results in the following conclusions.

(i) The nephelauxetic series breaks down in ternary compounds, at least in the cases of  $\text{Sm}^{2+}$  and  $\text{Eu}^{3+}$  in the present hosts.

(ii) The reduction of the parameters  $F_2$  and  $\zeta_{4f}$  is caused in general by two different covalency contributions, the central-field covalency or “central-charge screening” and the symmetry-restricted covalency or “ligand hybridization.” From a comparison of the relative decrease in  $F_2$  and  $\zeta_{4f}$  one can find out which of these two mechanisms is more dominant.

(iii) For small, trivalent lanthanide ions, like  $\text{Eu}^{3+}$ , the “central-charge screening” is dominant, whereas the “ligand hybridization” is the dominant mechanism in larger, divalent lanthanide ions like  $\text{Sm}^{2+}$ .

(iv) *Ab initio* calculations of the decrease in  $F_k$  for  $\text{Sm}^{2+}$  agree quantitatively with the experimental results within the mutual uncertainties of 10% of the changes.
