(Received 8 December 2016; revised manuscript received 5 March 2017; published 30 May 2017)

The electronic structure of recently discovered  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> with  $\sqrt{5} \times \sqrt{5}$  ordered Fe vacancies is calculated using first-principles density functional theory. We find that the ground state is an antiferromagnetic (AFM) insulator in agreement with the experimental observation. In K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>, it is known that the ground state is  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM ordered. But for this material, we find that the ground state is  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM ordered, in which the intrablock four Fe spins exhibit the collinear AFM order and the interblock spins on any two nearest-neighboring sites are antiparallel aligned. This state is about 130 meV/Fe lower in energy than the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM one. Electron doping can lower the energy of the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state and introduce a transition between these two states, suggesting that there is strong AFM fluctuation in FeSe-based materials upon doping. This provides a unified picture to understand the AFM orders in  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> and in alkali-metal intercalated FeSe materials.

DOI: [10.1103/PhysRevB.95.174523](https://doi.org/10.1103/PhysRevB.95.174523)**I. INTRODUCTION**

The discovery of iron-based superconductors has opened a new path to explore the unconventional mechanism of high-temperature superconductivity [1]. The superconducting transition temperatures of iron-based superconductors are closely related to the height of the anion from the Fe-Fe square lattice and the Fe-(As/Se)-Fe angle [2–4]. By intercalating atoms between FeSe layers to form  $A_{1-x}Fe_{2-y}Se_2$  compounds ( $A = K, Tl, Rb, \text{ or } Cs$ ), one can effectively modulate the height of the anion and raise the superconducting transition temperature of bulk FeSe from 8 K [5] to 27 ~ 48 K [6–11].

$A_{1-x}Fe_{2-y}Se_2$  possesses different kinds of Fe-vacancy orders. For example, the two commonly studied  $K_{2x}Fe_{2-x}Se_2$  compounds,  $K_2Fe_3Se_4$  (KFe<sub>1.5</sub>Se<sub>2</sub>) and  $K_2Fe_4Se_5$  (K<sub>0.8</sub>Fe<sub>1.6</sub>Se<sub>2</sub>), have the  $\sqrt{2} \times 2\sqrt{2}$  and  $\sqrt{5} \times \sqrt{5}$  Fe-vacancy orders, respectively. These two compounds were predicted to be AFM semiconductors by the first-principles calculations [12,13] and later confirmed by the experimental measurements [14–16]. Another kind of Fe-vacancy orders has also been observed [17]. The stoichiometric compound KFe<sub>2</sub>Se<sub>2</sub> without Fe vacancies is unstable against mesoscopic phase

separation [18–21]. But it can be stabilized and become a high- $T_c$  superconductor [22,23] by proximity to K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>.

Recently, a series of  $\beta$ -Fe<sub>1-x</sub>Se materials without metal intercalations but with Fe vacancies were synthesized. Through the measurement of electron microscopy, Fe vacancies are also found to be ordered and mainly in the phases with  $\sqrt{2} \times \sqrt{2}$ ,  $\sqrt{5} \times \sqrt{5}$ , and  $\sqrt{10} \times \sqrt{10}$  vacancy orders [24]. It indicates that the Fe-vacancy order is a common feature of FeSe-based superconductors. Furthermore, it was found that most of the  $\beta$ -Fe<sub>1-x</sub>Se samples synthesized in laboratory are in the  $\sqrt{5} \times \sqrt{5}$  phase, and the compound with such a vacancy order, i.e.  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>, is an AFM insulator [24,25]. As both  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> and K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub> have the same Fe-vacancy orders, it is interesting to know whether they have the same magnetic order in the ground states.

In this paper, we present the result for the electronic and magnetic structures of  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> with the  $\sqrt{5} \times \sqrt{5}$  Fe-vacancy order obtained by the first-principles density functional calculations. We find that  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> is an insulator with a  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM order. In this AFM ordered state, each Fe block contains four Fe spins which are collinear AFM aligned. The band gap of  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> in this  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM phase is found to be 290 meV, in agreement with the experimental observation [24,25]. This AFM order is stable against light electron doping. It is replaced by the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order

†txiang@iphy.ac.cn

(which is also the AFM order observed in  $K_2Fe_4Se_5$ ) when the doping level exceeds 1.7 electrons per  $Fe_4Se_5$  formula.

## II. COMPUTATIONAL DETAILS

In our calculations the plane wave basis method is used [26]. We adopt the generalized gradient approximation (GGA) of Perdew-Burke-Ernzerhof [27] for the exchange-correlation potentials. The ultrasoft pseudopotentials [28] are used to model the electron-ion interactions. After full convergence test, the kinetic energy cutoff and the charge density cutoff of the plane wave bases are taken to be 45 Ry and 480 Ry, respectively. Our calculation is done with a  $\sqrt{5} \times \sqrt{5} \times 1$  tetragonal unit cell which contains one FeSe layer with 8 Fe atoms, 2 vacancies, and 10 Se atoms. A mesh of  $8 \times 8 \times 10$   $k$  points is used to sample the Brillouin zone of the  $\sqrt{5} \times \sqrt{5} \times 1$  unit cell. The Gaussian broadening technique of width 0.002 Ry is used in the calculation of metallic states. The convergence is tested with a denser  $16 \times 16 \times 20$   $k$  mesh. There are two degenerate ground states, corresponding to the two degenerate chiral structures of the  $\sqrt{5} \times \sqrt{5}$  lattice [13,29]. We choose the right-chiral structure to do the calculation.

## III. RESULTS AND ANALYSIS

For the vacancy ordered  $\beta$ - $Fe_4Se_5$ , there are eight Fe atoms in each  $\sqrt{5} \times \sqrt{5} \times 1$  unit cell. These eight Fe atoms can be divided into two blocks. One block contains the four Fe atoms in the middle of the unit cell enclosed by the blue box as shown in Fig. 2, and the other contains the rest of the four Fe atoms.

The nonmagnetic (NM) phase of  $\beta$ - $Fe_4Se_5$  is metallic. Figure 1 shows the band structure and the partial density of states in the NM state. There are two bands crossing the Fermi level, forming one pillar-shaped hole Fermi surface along the  $\Gamma$ -Z line [Figs. 1(c) and 1(e)] and one windmill-type electron Fermi surfaces around the zone center [Figs. 1(d) and 1(f)]. The low-energy physics is governed by Fe 3d orbitals, since the density of states (DOS) in the energy range from  $-2.5$  eV to 1.0 eV is contributed mainly by Fe 3d electrons.

The ground state, or the lowest energy state, of  $\beta$ - $Fe_4Se_5$  in the  $\sqrt{5} \times \sqrt{5}$  vacancy ordered phase is AFM ordered. In order to determine the magnetic structure of the ground state, we have calculated the electronic structures for all ten nonequivalent AFM states allowed in a  $\sqrt{5} \times \sqrt{5}$  lattice. Figure 2 shows the spin configurations of these ten AFM states, labeled from AFM-*a* to AFM-*j*. These states can be divided into three groups, depending on the number of up spins in the middle four Fe atoms, which is called an Fe block, within each unit cell enclosed by the blue square. The first group contains the spin configurations represented by (AFM-*a*)-(AFM-*c*) with just one up spin in an Fe block. The second one consists of the spin configurations represented by (AFM-*d*)-(AFM-*i*) with two up spins in an Fe block. There is one spin configuration, i.e., AFM-*j*, in the third group. It contains four up spins in an Fe block. The AFM states with one and three up Fe spins in an Fe block are energetically degenerate and physically equivalent. The states with two up spins inside an Fe block can have either a collinear AFM order [Figs. 2(d)-2(g)] or a checkerboard one [Figs. 2(h) and 2(i)]. Among these states,

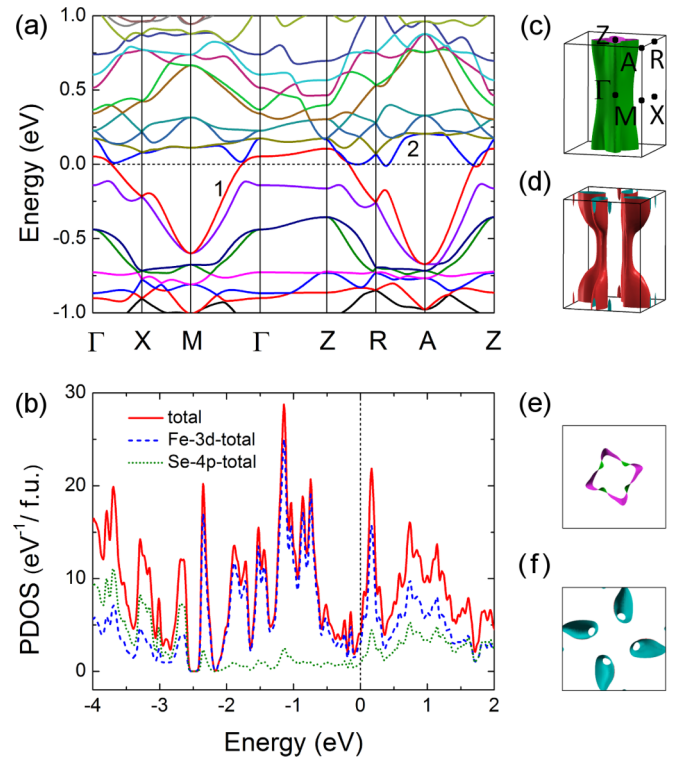

FIG. 1. Electronic structures of  $\beta$ - $Fe_4Se_5$  with the  $\sqrt{5} \times \sqrt{5}$  Fe-vacancy order in the nonmagnetic phase. (a) Band structures. The Fermi energy is set to zero. (b) Orbital-resolved partial density of states per formula of  $\beta$ - $Fe_4Se_5$ . (c) and (d) Fermi surfaces corresponding to the energy bands labeled by the Arabic numbers, 1 and 2, shown in (a), respectively. The high-symmetry points in the Brillouin zone are given in (c). (e) and (f) Top views of the two Fermi surfaces.

AFM-*j* is the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order, which is the magnetic order observed in the ground state of  $K_2Fe_4Se_5$ .

The relative energies of the ten AFM states with respect to the energy of the NM state are given in Table I. The ground state of  $\beta$ - $Fe_4Se_5$  is that shown in Fig. 2(f), namely the state labeled by AFM-*f*. It is a  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state. A similar AFM state, called the pair-checkerboard AFM state, was found to be the ground state of bulk  $\beta$ -FeSe based on the first-principles electronic structure calculations [30]. AFM-*f* can be regarded as a realization of this pair-checkerboard AFM order on the  $\sqrt{5} \times \sqrt{5}$  Fe-vacancy ordered lattice.

In the ground state, the lattice undergoes a tetragonal to monoclinic structure transition induced by the spin-lattice interaction. This changes the angle  $\varphi$  defined in Fig. 2(f) from  $90^\circ$  to  $89.2^\circ$  with an energy gain of 0.8 meV/Fe. Consequently, there is a tiny difference between the lattice parameters along the *a* and *b* axes, which are equal to 8.4519 Å and 8.4855 Å, respectively. This kind of structure transition is similar to the tetragonal-orthorhombic phase transition observed in other parent compounds of iron-based superconductors [31–34].

Figure 3 shows the band structure of  $\beta$ - $Fe_4Se_5$  in the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state obtained with a tetragonal unit cell by ignoring the monoclinic distortion. It indicates

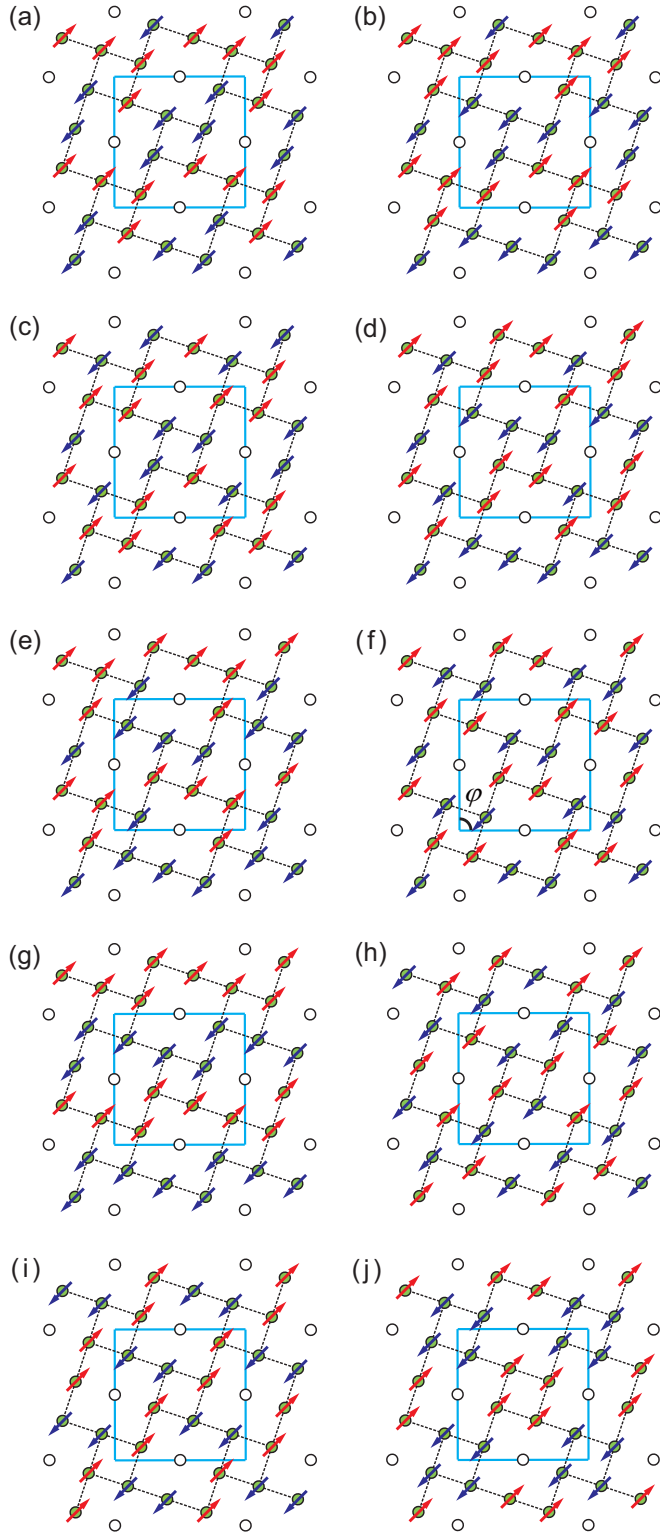

FIG. 2. Schematic top views of ten possible AFM orders, labeled from AFM-*a* to AFM-*j*, in each FeSe layer. The  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM order shown in (f) is the magnetic structure for the ground-state of  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>. The squares enclosed by the blue lines denote the unit cells. The filled and empty circles represent Fe atoms and Fe vacancies, respectively. The up and down Fe spins are represented by red and blue arrows, respectively.

TABLE I. Total energies, averaged magnitudes of the magnetic moments of Fe spins ( $|M|$ ), and band gaps of the ten AFM orders shown in Fig. 2. The energy of NM is set to zero.

AFM states	energy (meV/Fe)	$ M $ ( $\mu_B$ )	band gap (meV)
AFM- <i>a</i>	-127.4	2.48	0.0
AFM- <i>b</i>	-77.8	2.53	82.6
AFM- <i>c</i>	-188.9	2.72	208.5
AFM- <i>d</i>	-155.5	2.66	163.6
AFM- <i>e</i>	-114.0	2.53	75.7
AFM- <i>f</i>	-245.6	2.70	290.0
AFM- <i>g</i>	-20.3	2.29	0.0
AFM- <i>h</i>	-168.4	2.47	0.0
AFM- <i>i</i>	-207.7	2.66	20.8
AFM- <i>j</i>	-115.8	2.35	0.0

clearly that  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> is an AFM insulator with a direct energy gap of about 290 meV, in agreement with the experimental observation [24,25].

Figure 4 shows the orbital-resolved partial DOS in the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state with tetragonal symmetry. This AFM state is invariant under the following two kinds of transformations: One is to combine an *ab*-plane reflection with a fractional translation of  $(-1/2, 1/2, 0)$ , the other is to take a spin inversion and then a  $180^\circ$  rotation around the *c* axis. This symmetry property ensures the spin-up/down DOS at an Fe atom to equal the spin-down/up DOS at the diagonal Fe atom inside the same block. Thus we need only to show the orbital-resolved partial DOS for two Fe atoms, labeled by Fe<sub>1</sub> and Fe<sub>2</sub> in the figure. For Fe<sub>1</sub>, the five up-spin orbitals are almost completely filled, but the five down-spin orbitals are only partially filled. The DOS at Fe<sub>2</sub> behaves similarly, but the up and down spins are reversed. The magnetic moment of Fe<sub>2</sub> is slightly larger than that of Fe<sub>1</sub>. This leads to the difference

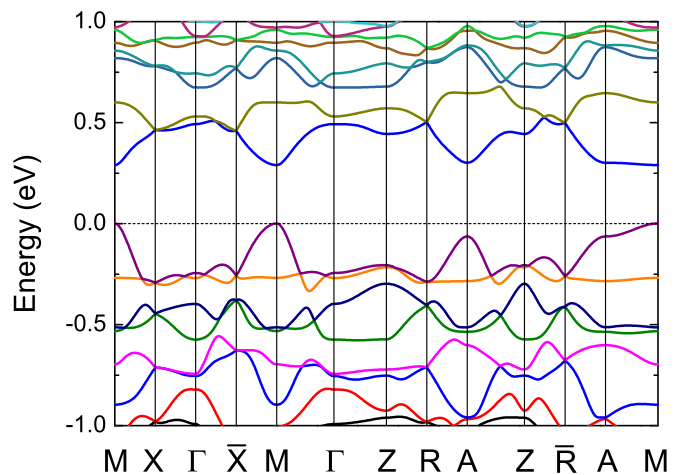

FIG. 3. Calculated electronic band structure of  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> in the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state with a tetragonal unit cell. The top of the valance band energy is set to zero. The Brillouin zone is the same as that in Fig. 1(c). The fractional coordinates of *X*,  $\bar{X}$ , *R*, and  $\bar{R}$  with respect to the reciprocal lattice vectors are (0.0, 0.5, 0.0), (0.5, 0.0, 0.0), (0.0, 0.5, 0.5), and (0.5, 0.0, 0.5), respectively.

FIG. 4. Orbital-resolved partial density of states (PDOS) for the five Fe 3d orbitals at (a) site Fe<sub>1</sub> and (b) site Fe<sub>2</sub> in the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state. The spins of Fe<sub>1</sub> and Fe<sub>2</sub> are highlighted by large arrows. The magnetic moments of these two Fe atoms are given in the corresponding figures.

in the DOSs between the up/down-spin part of Fe<sub>1</sub> and the down/up-spin one of Fe<sub>2</sub>. The unoccupied states are mainly contributed by  $d_{z^2}$  and  $d_{xy}$  orbitals.

We also find that the AFM states defined by AFM-*b*, AFM-*c*, AFM-*d*, AFM-*e*, and AFM-*i* are insulating. The excitation energy gaps are equal to 82.6 meV, 208.5 meV, 163.6 meV, 75.7 meV, and 20.8 meV, respectively. For AFM-*d*, the band gaps for the up- and down-spin electrons are not equal to each other, since the corresponding up- and down-spin configurations are not equivalent. They equal 163.6 meV and 233.1 meV, respectively. The other AFM states, including the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state, i.e., AFM-*j*, are metallic. This differs from the case in K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub> [12,14,16] where the ground state is blocked-checkerboard AFM ordered but insulating. AFM-*a* is in fact not a truly AFM state, although we initially set the up- and down-spin moments the same in the amplitude in our calculation. But after full optimization, we find that it is actually a ferrimagnetic state with a net magnetization about 1.97  $\mu_B$  per unit cell.

In  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>, the energy of the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state is 129.9 meV/Fe lower than the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM one. In contrast, the energy of the former is about 95.8 meV/Fe higher than the latter in K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>. Apparently, the difference results from the intercalation of K atoms in Fe<sub>4</sub>Se<sub>5</sub>: First, the intercalated K atoms impose a tensile strain on each Fe<sub>4</sub>Se<sub>5</sub> layer, which enlarges the *a*-axis lattice constant from 8.41 Å in  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> to 8.69 Å in K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>. Second, the intercalated atoms dope electrons into Fe<sub>4</sub>Se<sub>5</sub> layers.

To understand the effect of tensile strain introduced by K atoms, we calculate the energies of  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard and  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM states as a function of the *a*-axis lattice constant for  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>

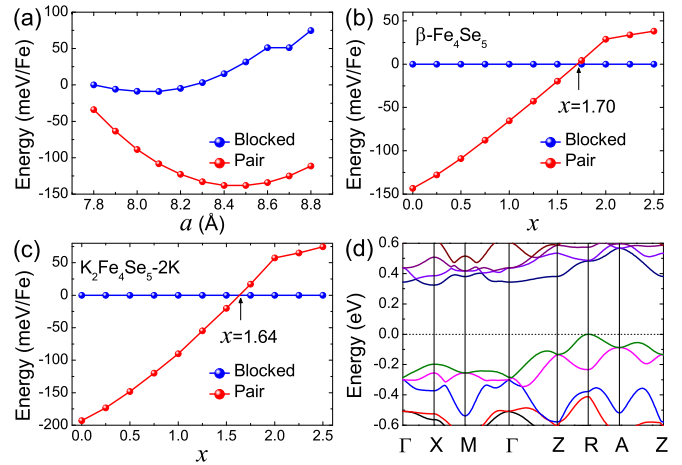

FIG. 5. Comparison between the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM and the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM states. (a) Total energies of these two AFM orders in  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> as functions of the *a*-axis lattice constant with tetragonal unit cell. The energy of the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state at  $a = 7.8$  Å is set to zero. (b) Relative energy of the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state (red) with respect to the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state (blue) as a function of doped electron concentration  $x$  for  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>. (c) Same as in (b) but for K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>-2K. (d) Band structure of the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state in the electron doped  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> with  $x = 2$ . Here  $x$  denotes the number of doped electrons per Fe<sub>4</sub>Se<sub>5</sub> formula.

with tetragonal unit cell. The lattice constant along the *c* axis and internal atomic positions are relaxed to minimize the total energy. In a wide range of the *a*-axis lattice constant, as shown in Fig. 5(a), we find that the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM order is more stable than the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM one. It suggests that the difference between  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> and K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub> is not due to the tensile strain effect.

To understand the charge doping effect, we introduce extra electrons to  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> and to K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub> with all K atoms removed (namely, K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>-2K). A jellium background with positive charge is introduced to compensate the doped electrons and to avoid numerical divergence in the calculation. Note that different AFM states have different optimized lattice constants. For example, the optimized lattice constants are  $a = 8.4682$  Å and  $c = 6.5241$  Å in the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state, and  $a = 8.1092$  Å and  $c = 6.2119$  Å in the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order of  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>. In order to avoid the complication introduced by the lattice parameters, we do the calculation by taking the experimental lattice constants, i.e.,  $a = 8.41$  Å and  $c = 5.47$  Å for  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> [24],  $a = 8.6929$  Å and  $c = 14.0168$  Å for K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>-2K [14].

For both materials without electron doping, we find that the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM state is lower in energy than the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard one [Figs. 5(b) and 5(c)]. Upon electron doping, the energy difference between these two states gradually decreases. A reversion in the total energy happens at a critical doping roughly equal to 1.7 electrons per formula for both  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> and K<sub>2</sub>Fe<sub>4</sub>Se<sub>5</sub>-2K. The  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state is 57.5 meV/Fe

lower than the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard one by adding two electrons per formula to  $\text{K}_2\text{Fe}_4\text{Se}_5\text{-}2\text{K}$ . Here  $\text{K}_2\text{Fe}_4\text{Se}_5\text{-}2\text{K} + 2e$  is isoelectronic to  $\text{K}_2\text{Fe}_4\text{Se}_5$ . Thus adding electrons to  $\text{Fe}_4\text{Se}_5$  layers reproduces correctly the ground-state AFM order of  $\text{K}_2\text{Fe}_4\text{Se}_5$ . It suggests that the difference in the magnetic orders between  $\beta\text{-Fe}_4\text{Se}_5$  and  $\text{K}_2\text{Fe}_4\text{Se}_5$  results mainly from the doping effect introduced by the intercalated K atoms. Furthermore, by doping two electrons per formula to  $\beta\text{-Fe}_4\text{Se}_5$ , we find that the metallic  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state becomes insulating, with an energy gap of 324 meV [Fig. 5(d)] (see Appendix A for the evolution of band structure). This is reminiscent of the insulating AFM state of  $\text{K}_2\text{Fe}_4\text{Se}_5$  [13].

With the increase of electron doping, we find that the nearest-neighboring Fe-Fe bond length inside the inner Fe block decreases. This leads to a tetramer lattice distortion of Fe atoms, in both the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard and the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM states. The tetramer distortion also exists in the ground state of  $\text{K}_2\text{Fe}_4\text{Se}_5$  [13]. It is in fact this tetramer distortion that stabilizes the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order in  $\text{K}_2\text{Fe}_4\text{Se}_5$ . To check how important this effect is in  $\beta\text{-Fe}_4\text{Se}_5$ , we carry out a total-energy calculation for this material without any tetramer distortion by using the lattice parameters obtained from the bulk  $\beta\text{-FeSe}$ . We find that the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state is about 27.8 meV/Fe higher in energy than the  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard one at the doping of two electrons per  $\text{Fe}_4\text{Se}_5$  formula. This shows that it is the tetramer lattice distortion enhanced by electron doping that lowers the energy of the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state.

The above results are obtained without considering the van der Waals (vdW) interaction between FeSe layers. This overestimates the lattice constant along the  $c$  axis. If the vdW correction [35,36] is taken into account, we find that the ground state is still  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM insulator. The band gap is 172 meV, and the  $a$ - and  $c$ -axis lattice constants are, respectively, 8.2440 Å and 5.5619 Å, in agreement with the experimental results [24].

#### IV. SUMMARY

In conclusion, we have studied the electronic and magnetic structures of  $\beta\text{-Fe}_4\text{Se}_5$ . Similar to  $\text{K}_2\text{Fe}_4\text{Se}_5$ , we find that the ground state of  $\beta\text{-Fe}_4\text{Se}_5$  is an AFM insulator. But the ground state is  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM ordered, unlike in  $\text{K}_2\text{Fe}_4\text{Se}_5$  where the ground state is  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM ordered. The band excitation gap of  $\beta\text{-Fe}_4\text{Se}_5$  is 290 meV, in agreement with the experimental result. The  $\sqrt{5} \times \sqrt{5}$ -pair-checkerboard AFM order is robust against the lattice tensile strain. But electron doping, introduced by extra Fe or intercalated alkali-metal atoms, can turn it into a  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM state above a critical doping level.

**APPENDIX: EVOLUTION OF BAND STRUCTURE AND DOS FOR  $\sqrt{5} \times \sqrt{5}$ -BLOCKED-CHECKERBOARD AFM ORDER UPON ELECTRON DOPING**

By adding two electrons per formula to  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub>, the metallic  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order becomes insulating. In this appendix, we present the evolution of band structure and DOS for the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order upon electron doping (see Fig. 6). Without electron doping, the two empty energy bands above the conduction band almost have no overlap in energy. This results in a very small

DOS at about 0.3 eV [Fig. 6(a)]. When extra electrons are introduced, an energy gap is opened between these two energy bands, which is further enlarged by increasing the electron doping concentration. In the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order, each unit cell contains two Fe<sub>4</sub>Se<sub>5</sub> formulas. Thus there are in fact four electrons doped to  $\beta$ -Fe<sub>4</sub>Se<sub>5</sub> per unit cell for  $x$  equal to 2. These four electrons will fully occupy the two energy bands below the opened energy gap. As a consequence, the  $\sqrt{5} \times \sqrt{5}$ -blocked-checkerboard AFM order becomes an insulator.
