(Received 4 August 2017; revised manuscript received 5 September 2018; published 21 November 2018)

We search for stable compounds of boron and oxygen at pressures from 0 to 500 GPa using the *ab initio* evolutionary algorithm USPEX. Only two stable stoichiometries of boron oxides, namely, B_6O and B_2O_3 , are found to be stable, in good agreement with experiment. A hitherto unknown phase of B_6O at ambient pressure, $Cmcm-B₆O$, has recently been predicted by us and observed experimentally. For $B₂O₃$, we predict three previously unknown stable high-pressure phases—two of these $(Cmc2₁$ and $P2₁2₁2₁$ are dynamically and mechanically stable at ambient pressure, and should be quenchable to ambient conditions. Their predicted hardnesses, reaching 33–35 GPa, make them harder than SiO₂-stishovite. These are the hardest known oxides (if one disregards B_6O , which is essentially a boron-based insertion compound). Under pressure, the coordination number of boron atoms changes from 3 to 4 to 6, skipping fivefold coordination.

I. INTRODUCTION

Boron (B) is arguably the most complicated element in the Periodic Table, with as many as 16 allotropes experimentally reported, most of which are probably impurity-stabilized. Well-established α , β , γ , and tetragonal *T* allotropes are superhard, and have been confirmed to be pure boron allotropes [\[1\]](#page-5-0). Recently, yet another pure bulk modification of boron, τ -B $[2]$, and two-dimensional (2D) allotropes of boron, borophenes, were identified [\[3,4\]](#page-5-0). Boron oxide B_2O_3 and suboxide B_6O are well established, but there are also controversial compounds proposed in the literature [\[4–15\]](#page-5-0).

To date, two crystalline forms of B_2O_3 are known: B_2O_3 -I [\[5\]](#page-5-0) (ambient-pressure form) and B_2O_3 -II [\[6\]](#page-5-0) (high-pressure form). B_2O_3 -I is composed of BO_3 planar triangular units, while B_2O_3 -II is made of BO_4 tetrahedra. The change of coordination number from 3 to 4 is similar to the structural transformation in the B_2O_3 glass under pressure [\[7\]](#page-5-0). However, the coordination number change in B_2O_3 glass under pressure is not without controversy [\[8–10\]](#page-5-0). Brazhkin *et al.* [\[8\]](#page-5-0) observed the transformation of $^{[3]}B \rightarrow$ $^{[4]}B$ (the superscript is the coordination number) by x-ray diffraction in B_2O_3 glass under pressure, and predicted one more transformation to $^{[6]}B$ using first-principles simulations at high pressure. Only four months later, Trachenko *et al.* [\[9\]](#page-5-0) reported the transformation $BO_3 \rightarrow$

 $BO_4 \rightarrow BO_5 \rightarrow BO_6$ for the local coordination environments in B_2O_3 glass under pressure; and a similar trend was also observed by Vegiri and Kamitsos $[10]$ in 0.3LiO-B₂O₃ glass.

Boron suboxides, such as $B_2O[11]$ $B_2O[11]$, $B_6O[12]$ $B_6O[12]$, $B_{13}O_2[13]$ $B_{13}O_2[13]$, B_7O [\[14\]](#page-5-0), and $B_{22}O$ [\[15\]](#page-5-0), have been reported and, if confirmed, could be promising superhard materials. Among these, B_2O (though studied by some theorists [\[16\]](#page-5-0)), had already been ruled out [\[17\]](#page-5-0). B_6O , $B_{13}O_2$, B_7O , and $B_{22}O$ can be considered as insertion phases based on rhombohedral *α*-boron structure with icosahedral B_{12} units and interstitial oxygens. B_6O is the most extensively studied phase among them, and it was synthesized at ambient pressure $[18]$, as opposed to diamond $[19]$ and cubic BN [\[20\]](#page-5-0), which are synthesized at high pressure. Given the numerous controversies in the literature, we decided to perform a thorough study of the structures and stability of B-O compounds at normal and high-pressure conditions by employing a systematic and unbiased first-principles crystal structure and compound prediction method.

II. METHOD OF CALCULATION

We used the *ab initio* evolutionary algorithm USPEX [\[21–23\]](#page-5-0), which can simultaneously find the stoichiometry and crystal structures of all stable compounds in a multicomponent system. In our searches at each pressure point, the initial population included 120 structures with up to 32 atoms per primitive cell, with all subsequent generations consisting of 50 structures produced by heredity (30%), transmutation (20%),

FIG. 1. Thermodynamic stability of boron oxides. (a) Pressure-composition phase diagram of the B-O system. (b) Thermodynamic convex hulls of the B-O system at selected pressures. Filled circles represent stable compounds; open circles denote metastable compounds. ΔH is the enthalpy of formation per atom (for details of the calculation process, see the Supplemental Material [\[31\]](#page-5-0)).

softmutation (20%), and random symmetric generator (30%). Structure relaxations and total energy calculations were done within the generalized gradient approximation (GGA) [\[24\]](#page-5-0) as implemented in the VASP [\[25\]](#page-5-0) code. We used the PAW [\[26\]](#page-5-0) method to represent core electrons and their effect on valence electrons, and the kinetic energy cutoff for valence wave functions was set to 600 eV, which gives excellent convergence of energy differences and stress tensors. Brillouin zone sampling was done with uniform Γ -centered k meshes with the resolution $2\pi \times 0.06 \text{ Å}^{-1}$ within USPEX searches and $2\pi \times 0.04$ Å⁻¹ for further calculations of physical properties. Phonon dispersions were calculated using the finitedisplacement method as implemented in the PHONOPY [\[27\]](#page-5-0) code. Hardness was estimated using the empirical Chen-Niu [\[28\]](#page-5-0) and Lyakhov-Oganov models [\[29\]](#page-5-0). At pressures below 5 GPa we included the van der Waals correction using the DFT-D2 method of Grimme [\[30\]](#page-5-0).

III. RESULTS AND DISCUSSION

Variable-composition calculations were performed at pressures of 0, 20, 50, 100, 150, 200, 300, 400, and 500 GPa. We found that compositions B_2O_3 , $B_{13}O_2$, BO, B_2O , B_6O , $B_{12}O$, and $B_{24}O$, are stable or close to the convex hull, which can be compared with the reported compositions, such as B_2O_3 [\[7\]](#page-5-0), $B_{13}O_2$ [\[11\]](#page-5-0), B_2O [11], B_4O [\[15\]](#page-5-0), B_6O [\[18\]](#page-5-0), B_7O [\[14\]](#page-5-0), B_8O [\[15\]](#page-5-0), $B_{10}O$ [15], and $B_{22}O$ [15]. For all the found and reported compositions, we carried out fixed-composition evolutionary searches at 0, 20, 40, 60, 80, 100, 150, 200, 250, 300, 350, 400, 450, and 500 GPa (up to 37 atoms per cell) to find the most stable structures. After this, the final pressure-composition phase diagram and convex hulls of the B-O system were constructed (see Fig. 1).

As can be seen from Fig. $1(b)$ and Fig. S1 in the Sup-plemental Material [\[31\]](#page-5-0), B₂O, B₄O, B₇O, B₁₁O, B₁₂O, and $B₂₄O₃$ have enthalpies of formation near (though slightly above) the convex hull. Only B_2O_3 and B_6O lie on the convex hull, indicating stability of only these two compounds, which is in good agreement with the vast majority of experimental results $[32,33]$. B₆O is stable below 94 GPa; at higher pressures, B_2O_3 remains the only stable boron oxide (see Fig. 1).

Surprisingly, *Cmcm*-B₆O, rather than the well-known $R\bar{3}m-B_6O$ (Fig. 2) [\[18\]](#page-5-0), is found to be the stable phase of B_6O in the whole pressure range of 0–94 GPa; see Figs. $1(a)$ and Fig. S2 in the Supplemental Material online [\[31\]](#page-5-0)). The enthalpy difference between these two structures is small (at ambient pressure it is only 1.8 meV per formula unit, and increases slightly with pressure). This prediction was published [\[12\]](#page-5-0) and then our predicted *Cmcm*-B₆O phase was experimentally confirmed [\[34\]](#page-5-0).

Below we focus on B_2O_3 . We found the following sequence of pressure-induced phase transitions:

$$
P3_121-B_2O_3(I) \stackrel{0.5}{\rightarrow} Cmc2_1-B_2O_3(II) \stackrel{46}{\rightarrow} P2_12_12_1-B_2O_3
$$

$$
\stackrel{133}{\rightarrow} Pmmn-B_2O_3 \stackrel{179}{\rightarrow} C2/m-B_2O_3.
$$

The numbers above the arrows indicate the calculated phase transition pressures in GPa (Table [I\)](#page-2-0), at zero Kelvin.

At pressures below 0.5 GPa, B_2O_3 is stable in the $P3_121$ structure (this is the well-known B_2O_3-I phase). B_2O_3-I is composed of corner-sharing triangular $BO₃$ units; this ultraflexible $[36]$ structure is shown in Fig. $3(a)$. From 0.5 to 46 GPa, $Cmc2_1-B_2O_3$, i.e., B_2O_3 -II [\[6\]](#page-5-0), is stable. B_2O_3 -II is composed of BO_4 tetrahedra, as shown in Fig. $3(b)$. The $BO_3 \rightarrow BO_4$ coordination number change also occurs in the vitreous B_2O_3 under pressure. The transition pressure point, 0.5 GPa, is consistent with experiments on glassy B_2O_3 [\[37\]](#page-5-0)

FIG. 2. Crystal structures of (a) $R\bar{3}m-B_6O$, (b) $Cmcm-B_6O$. Green (large) and red (small) spheres denote B and O atoms, respectively.

TABLE I. Crystal structures of experimentally known and recently predicted phases of B_6O and B_2O_3 .

and crystalline B_2O_3 [\[38\]](#page-5-0). Wu *et al.* [\[37\]](#page-5-0) observed ^[4]B in aluminoborosilicate glass at about 0.5 GPa, while Solozhenko *et al.* [\[38\]](#page-5-0) recently reported the transition from B_2O_3 -I to B_2O_3 -II at 2 GPa and 600 K.

FIG. 3. Crystal structures of (a) $P3_121-B_2O_3$, (b) $Cmc2_1-B_2O_3$, (c) $P2_12_12_1-B_2O_3$, (d) $Pmmn-B_2O_3$, and (e) $C2/m-B_2O_3$. [BO₄]: $[BO₆] = 3 : 1$ indicates the ratio of $[BO₄]$ and $[BO₆]$ polyhedra is 3:1 in the structure.

From 46 to 133 GPa, a previously unknown crystalline phase, $P2_12_12_1-B_2O_3$, is predicted to be stable. Its structure is made of BO_4 tetrahedra, just like $Cmc2_1-B_2O_3$; see Fig. $3(c)$. Between 133 and 179 GPa, another unique structure, *Pmmn*- B_2O_3 , is stable. Its structure contains both BO_4 tetrahedra and $BO₆$ octahedra. At higher pressures, above 179 GPa, $C2/m-B_2O_3$ is stable—and here, we again find both BO_4 tetrahedra and $BO₆$ octahedra. In addition, we also found an interesting phenomenon: The BO_4 tetrahedra and the BO_6 octahedra in $C2/m-B_2O_3$ disappear and convert into BO_3 units when pressure is released down to 0 GPa, as shown in Fig. S3 (Supplemental Material [\[31\]](#page-5-0)). This is in contrast with $Cmc2_1-B_2O_3$ and $P2_12_1B_2O_3$, which maintain their structure with $BO₄$ tetrahedra on decompression down to ambient pressure (where they are dynamically stable). The latter two phases may retain their original symmetry and dense structural topology under ambient pressure. $Cmc2_1-B_2O_3$ has for a long time been known to be quenchable in experiment [\[6\]](#page-5-0), which is in good agreement with our prediction. The computed hardnesses of $Cmc2_1$ - and $P2_12_12_1$ -phases of B_2O_3 at zero pressure are 35 and 33 GPa from the Chen-Niu model (or 34 and 29 GPa from the Lyakhov-Oganov model) (Table II). Moreover, both structures are dynamically and mechanically stable at ambient pressure (Fig. S4 in the Supplemental Material $[31]$ and Table [II\)](#page-3-0). This means that these

^aThese were calculated from the elastic constants and Voigt-Reuss-Hill averaging was used [\[41\]](#page-5-0).

 b Reference [\[42\]](#page-5-0).

^cReference [\[33\]](#page-5-0).

dReference [\[32\]](#page-5-0).

^gExperimental report of hardness of glass-like B₂O₃ (the local structure of glass-like B₂O₃ is closest to the structure of B₂O₃-I) and *β*-B₂O₃ $(i.e., B₂O₃-II), Ref. [43].$ $(i.e., B₂O₃-II), Ref. [43].$ $(i.e., B₂O₃-II), Ref. [43].$

two phases can be synthesized at high pressure (e.g., 5 and 50 GPa for $Cmc2_1-B_2O_3$ and $P2_12_12_1-B_2O_3$, respectively, with diamond-anvil cells or even a multianvil apparatus) and then may be decompressed to ambient pressure. They may be superior to B_6O , since B_6O is usually somewhat oxygen-deficient B_6O_x , where $x < 0.9$, and has rather poor crystallinity [\[39\]](#page-5-0). Moreover, even though B_6O , when prepared under high pressure, has excellent hardness, its fracture toughness is rather low [\[40\]](#page-5-0).

For B_2O_3 -I, both elastic moduli and hardness are overestimated (Table II), because B_2O_3 -I has an exotic layered-like structure, as shown in Fig. $3(a)$, with folded layers bridged by B-O bonds. Such a delicate structure is a difficult case for theory, largely because of the importance of van der Waals interactions, and we see a large difference between theoretical and experimental bulk moduli (Table II). For the other B-O phases, e.g., $Cmc2_1-B_2O_3$ and $P2_12_1B_2O_3$, as shown in Figs. [3\(b\)](#page-2-0) and $3(c)$, the situation is different. For example, the bulk modulus of $Cmc2_1-B_2O_3$ calculated by Voigt-Reuss-Hill theroy (164 GPa) is in good agreement with the experimental result (169.9 GPa; see Table II) [\[32\]](#page-5-0). The empirical Chen-Niu model is presently the most accurate model of hardness and has scored excellent successes, correctly reproducing experimentally measured hardnesses of many materials [\[28\]](#page-5-0). Therefore, the moduli and hardness of $Cmc2_1-B_2O_3$ and $P2_12_12_1-B_2O_3$ predicted by these empirical models are credible.

Glasses with high hardness have been in demand for many years. B_2O_3 is one of the most common glass materials and the hardness of $Cmc2_1-B_2O_3$ and $P2_12_1B_2O_3$ crystals is much higher than that of the known oxide glasses. It may be possible to increase the fraction of local environments similar to $Cmc2_1-B_2O_3$ or even $P2_12_12_1-B_2O_3$ in the glass and enhance the hardness of the glass by applying pressure in the process of glass production.

High-pressure-temperature techniques are very important for the synthesis of novel materials. To further study the high-pressure synthesis conditions, the pressure-temperature phase diagram of B_2O_3 (Supplemental Material [\[31\]](#page-5-0), Fig. S5) was constructed within the quasiharmonic approximation as implemented in the PHASEGO code [\[44\]](#page-5-0) (considering only solid phases). At room temperature, $P3_121-B_2O_3$ transforms into $Cmc2_1-B_2O_3$ at 2.9 GPa, which is consistent with exper-iment [\[38\]](#page-5-0), and $Cmc2_1-B_2O_3$ transforms into $P2_12_12_1-B_2O_3$ at 43 GPa and 300 K.

We analyze the relationship between the volume *V*, density *ρ*, average B-O bond length, coordination number of boron, charge transfer, and band gap as a function of pressure, as shown in Fig. [4.](#page-4-0) Volume and density as a function of pressure are shown in Figs. $4(a)$ and $4(b)$; one can see a series of volume discontinuities corresponding to first-order phase transitions. Bond lengths decrease with pressure for a given crystal structure—but at phase transitions involving increase of coordination number they sharply increase, resulting in a sawtooth-like dependence, and keeping roughly the same average B-O bond length, in the range 1.37–1.46 Å, in the enormous pressure range 0–500 GPa. At the same

FIG. 4. Volume *V*, density *ρ*, average B-O bond length, coordination number (C-N) of boron atoms, Bader charges, and the DFT band gap as a function of pressure in B_2O_3 .

time, atomic charges seem to be not sensitive to structural transitions [Fig. $4(e)$]. The DFT band gap [Fig. $4(f)$] shows large variations with pressure; the largest values roughly correspond to structures with tetrahedral coordination of boron atoms. For most phases, we see the normal tendency for the band gap to decrease with pressure, but notably, the band gap of $C2/m-B_2O_3$ increases with the increase of pressure from 179 GPa to at least 500 GPa.

In the sequence of phase transitions of B_2O_3 , i.e., $P3_121$ - $B_2O_3 \rightarrow Cmc2_1-B_2O_3 \rightarrow P2_12_12_1-B_2O_3 \rightarrow Pmmn-B_2O_3 \rightarrow$ $C2/m-B_2O_3$, there is a monotonic increase of the coordination number of boron atoms $(^{3]}B \rightarrow ^{[4]}B \rightarrow ^{[6]}B$), corresponding to the evolution $BO_3 \rightarrow BO_4 \rightarrow BO_6$ of boron coordination polyhedra. Fivefold coordination ^[5]B is not found in any of the stable phases.

IV. SUMMARY

To summarize, we have searched systematically for stable compounds in the B-O system in the pressure range 0– 500 GPa using the *ab initio* evolutionary algorithm USPEX. We found that there are only two thermodynamically stable oxides, B_6O and B_2O_3 . None of the previously discussed

 B_2O , B_7O , $B_{13}O_2$, or $B_{22}O$ are thermodynamically stable. Calculations reveal a theoretical ground state of superhard B6O at ambient conditions and three hitherto unknown stable high-pressure phases of B_2O_3 . Importantly, both of them are dynamically and mechanically stable at ambient pressure. Therefore, it is possible to synthesize them at high pressure and quench to ambient pressure: Synthesis of $Cmc2_1-B_2O_3$ and $P2_12_12_1-B_2O_3$ requires pressures in the ranges $0.5-46$ and 46–133 GPa, respectively (at zero Kelvin). A 6×8 double stage multianvil press with sintered diamond cubes as the second stage can generate pressure up to ∼50 GPa, with sample volumes \sim 1 mm³, suitable for synthesis of these phases, with hardness reaching 34 GPa; these phases are harder than stishovite (32 GPa) and represent the hardest known proper oxides $(B₆O$ suboxide is basically a boron-based insertion compound). Finally, we find that the sequence of coordination number changes of boron atoms in B_2O_3 under pressure is $^{[3]}B \rightarrow$ $^{[4]}B \rightarrow$ $^{[6]}B$.
