(Received 17 September 2019; published 14 November 2019)

In <sup>12</sup>O, the 2<sup>+</sup> state whose dominant configuration is <sup>10</sup>C(2<sup>+</sup>)  $\times \pi$  (sd)<sup>2</sup> should be populated in neutron removal from <sup>13</sup>O, and its primary decay is via  $2p$  emission to the  $2^+$  state of <sup>10</sup>C. My calculations predict that most of the events near  $E_{2p} = 3.5$  MeV in a recent  ${}^{12}O \rightarrow {}^{10}C + 2p$  experiment represent decays to the 2<sup>+</sup> state.

DOI: [10.1103/PhysRevC.100.054318](https://doi.org/10.1103/PhysRevC.100.054318)

## **I. INTRODUCTION**

Webb *et al.* [\[1\]](#page-1-0) recently reported results of an investigation of two-proton decays of 12O, which was formed in 1*n* removal from <sup>13</sup>O. Their <sup>10</sup>C + 2*p* spectrum contained three prominent peaks, at approximate energies of  $E_{2p} = 1.7, 3.8,$ and 6.5 MeV. The second of these gave clear indications of at least two contributions, a narrow one at 3.817(18) MeV and a much broader shoulder near 3.52(7) MeV. Their results are listed in Table I.

## **II. CALCULATIONS AND ANALYSIS**

Earlier, I had investigated the expected relative population of  $0^+$  and  $2^+$  states in <sup>12</sup>O in 1*n* removal from <sup>13</sup>O [\[2\]](#page-1-0). The relevant excitation energy range contains seven expected states—three  $0^+$  (only two of which are known) and four  $2^+$ states (only one of which was known prior to the work of Webb *et al.*). These are listed in Table II, along with their estimated 1*n* removal spectroscopic factors. The expected energies [\[2\]](#page-1-0) are only approximate and were obtained using a combination of weak coupling and a simple  $\left(\mathrm{sd}\right)^2$  shell-model calculation. Webb *et al.* attributed the peak at 6.5 MeV to decay of a  $2^+$  (presumably my  $2_4$ <sup>+</sup> state) state to the ground state (g.s.) of  ${}^{10}$ C.

As part of their analysis of  ${}^{12}O \rightarrow {}^{10}C + 2p$  events, Webb *et al.* obtained a refined value for the g.s. of  $\binom{11}{1}$ N. The energy and width of this resonance have varied quite a bit over the years. The reported energy in different experiments [\[3–8\]](#page-1-0) has

TABLE I. Results of Webb *et al.* for <sup>12</sup>O (energies and widths in MeV).

$J^{\pi a}$	$E_{2p}$	$E_{r}$	г	$\sigma$ (mb)
$0^{+}$	1.718(15)	$\theta$	0.051(19)	1.2(2)

$2^{+}$	6.493(17)	4.775(17)	0.754(25)	$4.8(12)^{b}$

a Labeling of Webb *et al.*

<sup>b</sup>If 0.27 of the 6.493-MeV yield decays to the  $2^+$  of <sup>10</sup>C.

varied from  $1.27$  [\[3\]](#page-1-0) to  $1.63$  [\[6\]](#page-1-0) MeV, with the width varying from  $0.24(24)$  [\[7\]](#page-1-0) to  $1.44(2)$  [\[3\]](#page-1-0) MeV. Theoretical resonance energies [\[9–12\]](#page-1-0) span a similar range, but calculated widths are all about 0.8 MeV or larger. The suggested value of Webb *et al.* is  $E = 1.378(15)$ ,  $\Gamma = 0.780(10)$ , both in MeV. Long ago, Sherr and I predicted an energy and width of 1.35(7) and 0.87(10) MeV, respectively, by using a potential model and mirror symmetry for the  $^{11}$ Be/ $^{11}$ N pair [\[9\]](#page-1-0). Somewhat later, I suggested adopting as a global average of experimental results the values  $E = 1.41(10)$  and  $\Gamma = 0.78(10)$  MeV [\[13\]](#page-1-0). This energy differed from the compiled value [\[8\]](#page-1-0), but the difference was less than  $2\sigma$ . These are listed in Table [III,](#page-1-0) along with two compiled values [\[8,14\]](#page-1-0).

If the shoulder in the <sup>12</sup>O  $\rightarrow$  <sup>10</sup>C + 2*p* spectrum at  $E_{2p}$  = 3.5 MeV is all due to the excited  $0^+$  state, its width of 0.98(18) MeV is close to that predicted  $[15]$  of 0.85(15) MeV (Table [IV\)](#page-1-0). However, its relative strength is very much larger than expected  $[2]$ , which is only about 20% of the g.s. Webb *et al.* suggested that some of the events at this energy may arise from decay of the higher  $2^+$  state to the  $2^+$  state of <sup>10</sup>C. Constraining the energy and width to agree with those of the 6.5-MeV peak provided a branching ratio  $2^{+}/g$ .s. of 0.27, but left about 60% of the shoulder as belonging to the excited  $0^+$ . Here, I explore another possibility, viz. the decay of another  $2^+$  state to the  $2^+$  of <sup>10</sup>C. This is the  $2^+$  state whose dominant structure is  ${}^{10}C(2^+) \times \pi$  (sd)<sub>0</sub>, which I have called  $2^{+}_{12}$ . This state should be relatively strong in 1*n* removal from <sup>13</sup>O and

<span id="page-1-0"></span>TABLE III. Properties of  $^{11}N$  (g.s.) from various sources.

Year	Source	E		Ref.
1999	Potential model calc.	1.35(7)	0.87(10)	[9]
2012	Experimental average	1.41(10)	0.78(10)	$\lceil 13 \rceil$
2012	Compilation	1.49(6)	0.83(3)	[8]
2017	Mass evaluation	1.32(5)	0.83(3)	[14]
2019	$^{12}O \rightarrow ^{10}C + 2p$	1.378(15)	0.78(1)	[1]

should have weak g.s. decays. Also, considering the proximity of the various expected  $2^+$  states, some mixing is inevitable.

Throughout the analysis, I use mirror symmetry for the pairs  $^{13}B/^{13}O$ ,  $^{12}O/^{12}Be$ ,  $^{11}N/^{11}Be$ , and  $^{10}C/^{10}Be$ . The dominant structure of the g.s. of  $^{13}B$  is

$$
{}^{13}B(g.s.) = A^{11}B_{1p}(g.s.) \times \nu (sd)_0^2 + B^{13}B_{1p}(g.s.).
$$

Estimates of  $A^2$  range from 0.21 to 0.33 [16–18]. For present purposes, I use  $A^2 = 0.25$ . The  $2^+$  state of <sup>12</sup>Be with configuration  ${}^{10}$ Be(2<sup>+</sup>)  $\times$   $\nu$  (sd)<sup>2</sup><sub>0</sub> will have a spectroscopic factor for proton removal from <sup>13</sup>B of  $S = A^2 S(^{11}B_{1p})$  $(g.s.) \to {}^{10}Be_{1p} (2^+))$ , which gives  $S = 0.43$ , using the *p*shell value of  $S = 1.71$  [19] for <sup>11</sup>B to <sup>10</sup>Be(2<sup>+</sup>). By mirror symmetry, this is also the *S* for neutron removal from  $^{13}$ O to the state labeled  $2<sub>2</sub>$  in Table [II.](#page-0-0)

For  $2 \rightarrow 0$  decays, sequential decay in which one nucleon has  $\ell = 0$  should prevail over simultaneous 2p decay; but for  $2 \rightarrow 2$  and  $0 \rightarrow 0$  decays via  $L = 0$ , simultaneous decay will compete favorably with sequential. (Here and elsewhere, I use lower-case  $\ell$  for a single nucleon and capital  $L$  for 2 (or more) nucleons.) I have calculated the expected widths of all the relevant states. These are listed in Table IV, along with previous values for some states [15,20–22]. From earlier work, if the first  $2^+$  state is at 2.1 MeV, its predicted width is 122 keV for sequential decay through the  $\binom{11}{9}$ (g.s.) and 18 keV for decay through the 1/2−, to be compared with the reported experimental width of 155(15) keV. For a pure  ${}^{10}C(2^+) \times (sd)^2$  state to decay to the  $2^+$  of  ${}^{10}C$ , the expected width for simultaneous 2*p* decay is 0.96 MeV. Of course, this value could be reduced if the state contains other components.

TABLE IV. Calculated widths (MeV) in <sup>12</sup>O.

<sup>12</sup> O state $E_x$		${}^{10}$ C state Process		$\Gamma_{\rm calc}$	Ref.	$\Gamma_{\rm exp}$
g.s.	0	g.s.	sim	0.031(3)	[21]	0.051(19)
			seq	0.058	$\lceil 20 \rceil$	
0 <sub>2</sub>	1.80	g.s.	seq	0.85(15)	[15]	(0.980(182))
2 <sub>1</sub>	2.1	g.s.	seq	0.140	$[22]$ , present $0.155(15)$	
2 <sub>2</sub>		g.s.	seq	0.33	present	
		$2^+$	sim	0.96	present	0.98?
$2_{4}$		g.s.	seq	0.38	present	0.754(25)
			sim	0.053	present	
		$2^{+}$	sim	0.35	present	

If the g.s. cross section of  $1.2(2)$  mb is correct, and my spectroscopic factors are approximately correct, the second  $0^+$  state should have  $\sigma = 0.23(4)$  mb, so that about 3(1) mb of the cross section for this shoulder is from other sources. If a spectroscopic factor of 0.36 corresponds to  $\sigma = 2.1(5)$  mb for the first  $2^+$ , then  $S = 0.43$  would correspond to  $\sigma = 2.5(6)$ mb for my second  $2^+$ . If all these events lead to decay to the  $2^+$  of <sup>10</sup>C, then this leaves about 0.5 mb (with a large uncertainty) of the shoulder yield to correspond to decay of  $24^+$  to  $2^+$ , to be compared to 1.3(8) mb suggested for this decay by Webb  $et$  al. Some g.s. decays from  $2<sub>2</sub>$  would improve the agreement. For example, if 25% goes to the g.s. (Table IV), then the second  $2^+$  state would account for 1.9(5) mb in the shoulder, leaving about 1.1 mb for  $24^+$ . If the two relevant  $2^+$  states are approximately degenerate, then it might be difficult to distinguish decays from them. Perhaps the somewhat different predicted widths (Table IV) might be useful in this regard.

## **III. CONCLUSION**

In summary, my calculations predict that most of the events near 3.5 MeV in the <sup>12</sup>O  $\rightarrow$  <sup>10</sup>C + 2*p* spectrum will be accompanied by a  ${}^{10}C\gamma$  ray. Looking for these coincident gammas would seem to be an important experiment.
