 (Received 18 August 2017; revised manuscript received 12 December 2017; published 19 January 2018)

Spectroscopic factors in ^{10}Be , ^{11}Be , and ^{12}Be , extracted from (d, p) , one-neutron knockout, and (p, d) reactions, are interpreted within the rotational model. Assuming that the ground state and first excited state of ^{11}Be can be associated with the $\frac{1}{2}[220]$ and $\frac{1}{2}[101]$ Nilsson levels, the strong-coupling limit gives simple expressions that relate the amplitudes of these wave functions (in the spherical basis) with the measured cross sections and derived spectroscopic factors. We obtain good agreement with both the measured magnetic moment of the ground state in ^{11}Be and the reaction data.

DOI: [10.1103/PhysRevC.97.011302](https://doi.org/10.1103/PhysRevC.97.011302)

Introduction. The lightest example of an “island of inversion” is that at $N = 8$, where the removal of $p_{3/2}$ protons from ^{14}C results in a quenching of the $N = 8$ shell gap [1–4]. This is evident with the sudden drop of the $E(2^+)$ energy in ^{12}Be relative to the neighboring even-even isotopes and the inversion of the ground state of ^{11}Be from the expected $1/2^-$ to the observed positive parity $1/2^+$ state.

The strong α clustering in ^8Be naturally suggests that deformation degrees of freedom will play an important role on the structure of the Be isotopes, a topic that has been extensively discussed in the literature (see Ref. [5] for a review). In fact, Bohr and Mottelson [6] proposed the effects of deformation to explain the inversion of the $1/2^+$ and the $1/2^-$ states.

In terms of a shell-model picture, the underlying physics of such inversions is rather well understood, with the neutron-proton interaction playing an important role [2–4,7]. Specifically for the case at $N = 8$, the combined effects of the $V_{p_{3/2}, p_{1/2}}^{\pi\nu}$ interaction and the lowering of the $s_{1/2}$ orbit due to weak binding [8] erode the expected shell gap, and the quadrupole force takes over, driving the system to deform.

Given the discussions above, it is of interest to understand the structure of neutron-rich Be isotopes within the Nilsson model [9,10] in a way that captures the main effects of the quadrupole force in a deformed mean field. Building on the arguments in Ref. [6], Hamamoto and Shimoura [11] presented a detailed interpretation of energy levels and available electromagnetic data on ^{11}Be and ^{12}Be in terms of single-particle motion in a deformed potential, using weakly bound one-particle wave functions calculated with a deformed Woods-Saxon (WS) potential instead of the standard harmonic-oscillator potential [12].

There are, of course, many theoretical approaches to describe the structure of neutron-rich ^{11}Be and ^{12}Be [13–20], which include ingredients the Nilsson model perhaps overlooks. Nevertheless, the deformed mean-field approach seems to capture the main physics ingredients [11]. In this work, we analyze spectroscopic factors, obtained from studies of the $^{11}\text{Be}(d, p)^{12}\text{Be}$ [17,21], $^{10}\text{Be}(d, p)^{11}\text{Be}$ [22,23], ^{12}Be one-neutron-knockout $(-1n)$ [24,25], and $^{11}\text{Be}(p, d)^{10}\text{Be}$ [16]

reactions, in the Nilsson strong-coupling limit. As we will show, the approach provides a satisfactory explanation of spectroscopic factors, in a simple and intuitive manner.

Method. In what follows, we use the formalism reviewed in Ref. [26], which we have recently applied to the $N = 20$ island of inversion [27]. As in Refs. [6,11], we associate the $1/2^+$ and the $1/2^-$ states in ^{11}Be to the Nilsson levels $\frac{1}{2}[220]$ and $\frac{1}{2}[101]$ respectively. In the spherical $|j, \ell\rangle$ basis, these wave functions take the form

$$\left|\frac{1}{2}[220]\right\rangle = C_{1/2,0}|s_{1/2}\rangle + C_{3/2,2}|d_{3/2}\rangle + C_{5/2,2}|d_{5/2}\rangle \quad (1)$$

$$\left|\frac{1}{2}[101]\right\rangle = C_{1/2,1}|p_{1/2}\rangle + C_{3/2,1}|p_{3/2}\rangle, \quad (2)$$

where $C_{j,\ell}$ are the associated Nilsson wave-function amplitudes.

For transfer reactions, such as (d, p) , the spectroscopic factors $(S_{i,f})$ from an initial ground state $|I_i K_i\rangle$ to a final state $|I_f K_f\rangle$ can be written in terms of the Nilsson amplitudes [26]:

$$S_{i,f} = \frac{(2I_i + 1)}{(2I_f + 1)} g^2 \langle I_i j K_i \Delta K | I_f K_f \rangle^2 C_{j,\ell}^2 \langle \phi_f | \phi_i \rangle^2, \quad (3)$$

where $g^2 = 2$ if $I_i = 0$ or $K_f = 0$ and $g^2 = 1$ otherwise, and $\langle \phi_f | \phi_i \rangle$ represents the core overlap between the initial and final states. A similar expression, without the spin factors, applies to the cases of $(-1n)$ and (p, d) .

Finally, we consider the 0^+ states in ^{12}Be as superpositions of the neutron levels, ν_1 and ν_2 , in Eqs. (1) and (2) respectively [11]

$$\begin{aligned} |0_1^+\rangle &= \alpha|\nu_1\bar{\nu}_1\rangle + \beta|\nu_2\bar{\nu}_2\rangle, \\ |0_2^+\rangle &= -\beta|\nu_1\bar{\nu}_1\rangle + \alpha|\nu_2\bar{\nu}_2\rangle, \end{aligned} \quad (4)$$

with $\bar{\nu}$ indicating the time-reverse orbit. The $|2_1^+\rangle$ is associated with the 2^+ member of the rotational band built on the $|0_1^+\rangle$ state.

Results. With the established framework for our calculations, we can derive specific formulas relating the Nilsson amplitudes $C_{j,\ell}$ to the experimental spectroscopic factors for the reactions considered here. The relations follow directly from Eqs. (1)–(3) and are given below for the four specific cases.

TABLE I. Summary of experimental relative spectroscopic factors in $^{10,11,12}\text{Be}$ compared to the Nilsson calculations using amplitudes empirically adjusted from a weighted fit to the data.

^aHere we consider the values obtained from their single-particle (SE) form factor analysis. See text for further discussion.

^bThe values correspond to two Warburton-Brown interactions (WBP) calculations.

^cValues are for the Warburton-Brown interactions WBT2 [WBT2¹].

A. $^{11}\text{Be}(d,p)^{12}\text{Be}$. For this first case, we start from the ^{11}Be $1/2^+$ ground state, and consider transfer of a single neutron in (d,p) to populate the 0_1^+ , 0_2^+ , and 2_1^+ states. Following directly from Eqs. (1)–(4), the relevant spectroscopic factors are

$$S_{1/2^+,0_1^+} = 2C_{1/2,0}^2\alpha^2,$$

$$S_{1/2^+,0_2^+} = 2C_{1/2,0}^2\beta^2,$$

and

$$S_{1/2^+,2_1^+} = \frac{2}{5}(C_{3/2,2}^2 + C_{5/2,2}^2)\alpha^2.$$

In Ref. [18], a shell-model-inspired solution was proposed to explain the spectroscopic factor data. In their analysis, the authors use simple mixed wave functions, which are naturally captured in the Nilsson model.

B. $^{10}\text{Be}(d,p)^{11}\text{Be}$. In this case, since we start from the ^{10}Be 0^+ ground state and the angular momentum selection rules imposed by the Clebsch-Gordan coefficients in Eq. (2), the spectroscopic factors directly project out the amplitudes of the wave functions in the spectroscopic factors:

$$S_{0^+,1/2^+} = C_{1/2,0}^2$$

and

$$S_{0^+,1/2^-} = C_{1/2,1}^2.$$

It is worth noting that this case has been studied in the particle-vibration coupling and deformed-core-plus-neutron cluster models in Refs. [14,15].

C. $^{12}\text{Be}(-1n)^{11}\text{Be}$. The case of neutron knockout is essentially equivalent to the previous examples, but we now have the addition of the core overlaps in Eq. (4) as we consider the $K = 1/2^+$ and $K = 1/2^-$ final states, with spectroscopic factors given by

$$S_{0_1^+,1/2^+} = 2C_{1/2,0}^2\alpha^2; \quad S_{0_1^+,5/2^+} = 2C_{5/2,2}^2\alpha^2$$

and

$$S_{0_1^+,1/2^-} = 2C_{1/2,1}^2\beta^2; \quad S_{0_1^+,3/2^-} = 2C_{3/2,1}^2\beta^2$$

D. $^{11}\text{Be}(p,d)^{10}\text{Be}$. Finally, the spectroscopic factors for the (p,d) reaction populating states in ^{10}Be reduce to

$$S_{1/2^+,0_1^+} = C_{1/2,0}^2$$

and

$$S_{1/2^+,2_1^+} = C_{5/2,2}^2.$$

In Ref. [16], the authors consider a particle-vibration coupling picture, suggesting an appreciable admixture of core excitation to explain their cross-section data.

In comparing with the experimental data (summarized in Table I), we have used the expressions above together with the condition of wave-function normalization to empirically adjust the amplitudes of the Nilsson states in Eqs. (1) and (2). In addition, we consider the measured magnetic moment (see the Appendix) of the ground state in ^{11}Be , $\mu = -1.6813(5)\mu_N$ [28], as a constraint. There are in total 12 relations connecting the experimental data to four unknown amplitudes which we

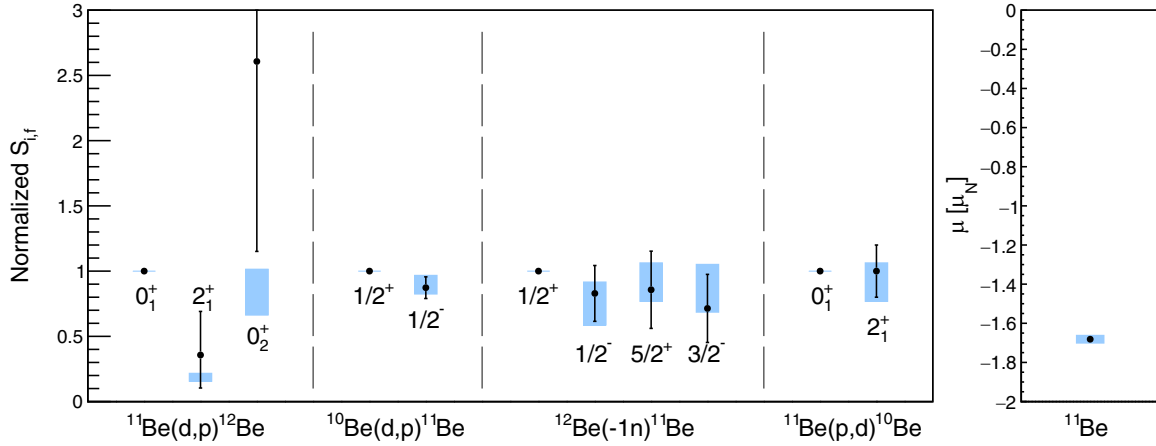

FIG. 1. Relative experimental spectroscopic factors and magnetic moment (data points) compared to the strong-coupling limit results obtained in our analysis (blue boxes), which encompass the 1σ confidence level in our fit.

determine from a χ^2 -minimization procedure. Given the possible systematic uncertainties in the determination of absolute spectroscopic factors, particularly from different experimental conditions and analysis, we have done a weighted fit of the relative spectroscopic factor values with respect to the ground-state transition for each of the data sets and of the absolute value of the ^{11}Be ground-state magnetic moment.

The following wave functions¹

$$\left| \frac{1}{2} [220] \right\rangle = -0.72(3) |s_{1/2}\rangle - 0.09(2) |d_{3/2}\rangle + 0.69(2) |d_{5/2}\rangle$$

$$\left| \frac{1}{2} [101] \right\rangle = 0.68(4) |p_{1/2}\rangle + 0.73(3) |p_{3/2}\rangle$$

and $\alpha = 0.74(4)$ and $\beta = 0.68(4)$ are obtained. The resulting spectroscopic factors are summarized in Table I and, with the magnetic moment, in Fig. 1, showing good agreement with the experimental data. The wave functions as well as α and β are fairly consistent with those used in Ref. [11], $\alpha = \beta = 0.707$.

A brief discussion is in order, regarding the experimental result of Ref. [16] quoted in Table I. We have adopted the average value corresponding to their single-particle (SE) form factor analysis. We note, however, that their alternate analysis using the vibrational (VIB) form factor yields a relative spectroscopic factor for the 2_1^+ state in the $^{11}\text{Be}(p,d)^{10}\text{Be}$ of 0.26(5). If we use this value instead, our fit finds a reduced amplitude of the $d_{5/2}$ component of the $\frac{1}{2} [220]$ wave function, but we still obtain good overall agreement with the experimental data.

There is continuing interest in this region of the nuclear chart, and with the availability of radioactive beams of ^{12}Be and ^{13}B as well as new instrumentation, further experimental work will be carried out. With this in mind, we take the Nilsson approach a little further and predict estimates for spectroscopic factors for the reactions $^{12}\text{Be}(d,p)^{13}\text{Be}$ and $^{13}\text{B}(d,^3\text{He})^{12}\text{Be}$ which are likely to be studied in the near future. There is some discrepancy in the literature about the low-lying level assignments of ^{13}Be [29], but in any scenario the $\frac{1}{2} [220]$ and $\frac{1}{2} [101]$ Nilsson levels play a center role (as in ^{11}Be). The calculations are straightforward and the results are summarized in Table II.

It is also of interest to consider proton spectroscopic factors within the Nilsson scheme for $Z = 5$ where the proton is expected to occupy the $\frac{3}{2} [101]$ level, an assignment supported by the ground state spin $3/2^-$ and measured magnetic moment in ^{13}B , $\mu = 3.1778(5)\mu_N$ [30], for which we calculate $\mu \approx 3.2\mu_N$. Since the level parentage is attributed only to the $p_{3/2}$ orbit, the spectroscopic factors depend only on the Clebsch-Gordan coefficients, and our predictions for the reaction $^{13}\text{B}(d,^3\text{He})^{12}\text{Be}$ are included in Table II.

Conclusion. We have analyzed spectroscopic factors in ^{11}Be and ^{12}Be , obtained from (d,p) , $(-1n)$, and (p,d) reactions, in the Nilsson strong-coupling limit. Using the formalism developed for studies of single-nucleon transfer reactions in deformed nuclei we derived, for the cases considered, simple formulas for spectroscopic factors in terms of the amplitudes of the deformed wave functions. These amplitudes were empirically adjusted to reproduce the experimental data, including the magnetic moment of the ^{11}Be ground state. We have also used these wave functions to make some predictions for reactions such as $^{12}\text{Be}(d,p)^{13}\text{Be}$ and $^{13}\text{B}(d,^3\text{He})^{12}\text{Be}$ that will likely be studied in the near future.

TABLE II. Predicted spectroscopic factors in the Nilsson scheme for the reactions $^{12}\text{Be}(d,p)^{13}\text{Be}$ and $^{13}\text{B}(d,^3\text{He})^{12}\text{Be}$.

| Initial state | Final state | Energy [MeV] | ℓ | Calculated $S_{i,f}$ |

Appendix. We present here the formulas used to calculate the magnetic moment (see Ref. [6]). For a $K = 1/2$ band, the magnetic moment of the $I = 1/2$ state is given by

$$\mu = \frac{1}{2}g_R + \frac{g_K - g_R}{6}(1 - 2b),$$

where $g_R \approx Z/A$ and g_K are the collective and single-particle gyromagnetic factors respectively, and b is the magnetic decoupling parameter.

The gyromagnetic factor g_K depends on the C_{jl} amplitudes through the following relation,

$$g_K = g_s \left(C_{1/2,0}^2 + \frac{1}{5}(C_{5/2,2}^2 - C_{3/2,2}^2) - 2\sqrt{\frac{24}{25}}C_{5/2,2}C_{3/2,2} \right),$$

and the magnetic decoupling parameter b is related to the decoupling parameter a ,

$$b = \frac{g_R a - (g_s + g_K)/2}{(g_K - g_R)},$$

with a ,

$$a = C_{1/2,0}^2 - 2C_{3/2,2}^2 + 3C_{5/2,2}^2.$$

Using the wave functions derived, the calculated gyromagnetic factor g_K , decoupling and magnetic-decoupling parameters for the ground state of ^{11}Be $g_K = -2.79$, $a = 1.93$, and $b = -1.27$ respectively. We note that, associating the $5/2^+$ state at 1.78 MeV with the second member of the rotational band, its energy is given by

$$E_{rot} = A \left[\frac{5}{2} \left(\frac{5}{2} + 1 \right) - a \left(\frac{5}{2} + 1 \right) \right].$$

With the rotational constant $A = 0.35$ MeV, determined from the 2^+ in ^{12}Be , we estimate $a = 1.85$, in excellent agreement with the value calculated from the magnetic moment.
