

Supersymmetric DBI equations in diverse dimensions from the BRS invariance of a pure spinor superstring

Sota Hanazawa^{*} and Makoto Sakaguchi[†]*Department of Physics, Ibaraki University, Mito 310-8512, Japan*

(Received 16 May 2019; published 5 August 2019)

We examine the BRS invariance of the open pure spinor superstring in the presence of background superfields on a Dp -brane. It is shown that the BRS invariance leads not only to boundary conditions on the spacetime spinors, but also to supersymmetric Dirac-Born-Infeld (DBI) equations of motion for the background superfields on the Dp -brane. These DBI equations are consistent with the supersymmetric DBI equations for a D9-brane.

DOI: [10.1103/PhysRevD.100.046006](https://doi.org/10.1103/PhysRevD.100.046006)

I. INTRODUCTION

Dirac-Born-Infeld (DBI) theory is known as a nonlinear generalization of Maxwell theory and may describe, along with the Wess-Zumino action, the low-energy effective dynamics on a single D-brane in string theory. The bosonic DBI action is derived from the world-sheet analysis of the bosonic open string [1]. A supersymmetric DBI action should be a part of the effective action on a D-brane in type II superstring theory. In the Ramond-Neveu-Schwarz (RNS) formulation, however, it is difficult to read off the target space geometry coupling to Ramond-Ramond fields, because space-time supersymmetry becomes manifest only after the Gliozzi-Scherk-Olive projection. So the RNS superstring has led to the only bosonic sector of the supersymmetric DBI action [2].

The Green-Schwarz (GS) formulation has an advantage in this direction. The Wess-Zumino term which ensures the κ -invariance of the world-volume action of a D-brane is constructed in [3]. In [4], the κ -symmetric approach, so-called the superembedding formalism [5], is shown to lead to linearized supersymmetric DBI equations of motion for a D9-brane, which have the ten-dimensional $\mathcal{N} = 2$ supersymmetry. Furthermore, in [6], the classical κ -invariance of an open GS superstring in an Abelian background is shown to imply that the background fields should satisfy full nonlinear equations of motion for a supersymmetric DBI action. The non-Abelian extension of this formalism is discussed in [7] as the boundary fermion formalism where

Chan-Paton factors describing coincident D-branes are replaced by boundary fermions.¹

Unlike the formulations mentioned above, the pure spinor formulation [23] enables us to quantize a superstring in a super-Poincaré covariant manner. In this formulation, the κ -symmetry in the GS formulation is replaced with the BRS symmetry. It is shown in [24], correspondingly to the κ -symmetry analysis [6], that the classical BRS invariance of an open pure spinor superstring leads to supersymmetric DBI equations of motion on a D9-brane, which have the nonlinear $\mathcal{N} = 1$ supersymmetry as well as the manifest $\mathcal{N} = 1$ supersymmetry. These equations precisely coincide with those obtained in the superembedding formalism [25]. Furthermore, the non-Abelian extension of supersymmetric DBI equations is proposed. In [26] (see also [27,28]), D-brane boundary states are constructed in the pure spinor formulation. Especially, calculating the disk scattering amplitude suggests that the coupling of the boundary state to the background fields will reproduce the DBI kinetic term and the Wess-Zumino term of the D9-brane effective action. These achievements might imply the fact that the low-energy effective theory on the D9-brane is determined uniquely by the ten-dimensional $\mathcal{N} = 2$ supersymmetry.

In this paper we will derive supersymmetric DBI equations of motion on a Dp -brane, as well as a D9-brane, from the BRS invariance of the open pure spinor superstring. Our approach is similar to that taken in [24] for a D9-brane. However the inclusion of Dirichlet components requires improvements which are not just a dimensional reduction of the case of a D9-brane. As in [24], we will provide two boundary terms, the counterterm S_b for the $\mathcal{N} = 1$ supersymmetry transformation of the world-sheet action S_0 and the background superfield coupling V as a

¹Other than this study, there have been many attempts to extend to the non-Abelian DBI theory based on various approaches [8–22].

relevant extension of the pure spinor vertex operator. It is found that the contribution of Dirichlet components in them cannot be determined unless considering the BRS invariance. In [24], by using nontrivial boundary conditions given by the general variation of $S_0 + S_b + V$, the BRS charge conservation leads to supersymmetric DBI equations for the D9-brane. On the other hand, we will show that supersymmetric DBI equations in diverse dimensions are extracted only from the BRS transformation of $S_0 + S_b + V$ under an identification on the D-brane position.

This paper is organized as follows. After introducing the type II pure spinor open superstring action in Sec. II, we construct the boundary term for the $\mathcal{N} = 1$ supersymmetry invariance of this action in Sec. III. In Sec. IV A, background superfield coupling is found by considering the modification of a vertex operator in the open pure spinor

superstring. In Sec. IV B, we confirm that these background superfields satisfy supersymmetric DBI equations of motion. The last section is devoted to summary and discussions. In addition, we give a brief review of the covariant approach for the ten-dimensional $\mathcal{N} = 1$ super-Yang-Mills theory in Appendix A. We will formulate a vertex operator in the open pure spinor superstring in Appendix B. We show that our result can be derived also from improving the method used in [24] to include Dirichlet components in Appendix C.

II. OPEN PURE SPINOR SUPERSTRING

The world-sheet action of the type II pure spinor open superstring [23] is given as

$$S_0 = \frac{1}{\pi\alpha'} \int dzd\bar{z} \left\{ \frac{1}{2} \partial x^m \bar{\partial} x_m + p_\alpha \bar{\partial} \theta^\alpha + \hat{p}_\alpha \partial \hat{\theta}^\alpha + \omega_\alpha \bar{\partial} \lambda^\alpha + \hat{\omega}_\alpha \partial \hat{\lambda}^\alpha \right\}, \quad (2.1)$$

where x^m ($m = 0, 1, \dots, 9$) is a ten-dimensional coordinate, θ^α and $\hat{\theta}^\alpha$ ($\alpha = 1, \dots, 16$) are left- and right-moving ten-dimensional Majorana-Weyl spinors, respectively, and λ^α and $\hat{\lambda}^\alpha$ are bosonic ghosts satisfying pure spinor constraints $\lambda \gamma^m \lambda = \hat{\lambda} \gamma^m \hat{\lambda} = 0$. The $(p_\alpha, \hat{p}_\alpha)$ and $(\omega_\alpha, \hat{\omega}_\alpha)$ are conjugate to $(\theta^\alpha, \hat{\theta}^\alpha)$ and $(\lambda^\alpha, \hat{\lambda}^\alpha)$, respectively. The world-sheet derivatives ∂ and $\bar{\partial}$ denote $\partial = \partial_\tau + \partial_\sigma$ and $\bar{\partial} = \partial_\tau - \partial_\sigma$, respectively. It implies $dzd\bar{z} = -\frac{1}{2} d\tau d\sigma$. The action is

invariant under the gauge transformations $\delta_\Lambda \omega_\alpha = \Lambda^m (\gamma_m \lambda)_\alpha$ and $\delta_{\hat{\Lambda}} \hat{\omega}_\alpha = \hat{\Lambda}^m (\gamma_m \hat{\lambda})_\alpha$. We use 16×16 symmetric matrices $\gamma_{\alpha\beta}^m$ and $\gamma^{m\alpha\beta}$ which are off-diagonal blocks of the 32×32 gamma matrices and satisfy $\gamma_{\alpha\beta}^m \gamma^{n\beta\gamma} + \gamma_{\alpha\beta}^n \gamma^{m\beta\gamma} = 2\gamma^{mn} \delta_\alpha^\gamma$. We frequently use the Fierz identity $\gamma_{m(\alpha\beta} \gamma_{\gamma)\delta}^m = 0$.

The action (2.1) is invariant under the ten-dimensional $\mathcal{N} = 2$ supersymmetry transformations,

$$\begin{aligned} \delta_\epsilon \theta^\alpha &= \epsilon^\alpha, & \delta_{\hat{\epsilon}} \hat{\theta}^\alpha &= \hat{\epsilon}^\alpha, & \delta_\epsilon x^m &= \frac{1}{2} \theta \gamma^m \epsilon + \frac{1}{2} \hat{\theta} \gamma^m \hat{\epsilon}, \\ \delta_\epsilon p_\alpha &= \frac{1}{2} \partial x^m (\gamma_m \epsilon)_\alpha - \frac{1}{8} (\epsilon \gamma^m \theta) (\gamma_m \partial \theta)_\alpha, & \delta_{\hat{\epsilon}} \hat{p}_\alpha &= \frac{1}{2} \bar{\partial} x^m (\gamma_m \hat{\epsilon})_\alpha - \frac{1}{8} (\hat{\epsilon} \gamma^m \hat{\theta}) (\gamma_m \bar{\partial} \hat{\theta})_\alpha, \end{aligned} \quad (2.2)$$

where parameters ϵ and $\hat{\epsilon}$ correspond to ten-dimensional Majorana-Weyl spinors. For an open superstring, we are left with a surface term,

$$\delta_\epsilon S_0 = \frac{1}{2\pi\alpha'} \int d\tau \left\{ \frac{1}{2} (\epsilon \gamma^m \theta - \hat{\epsilon} \gamma^m \hat{\theta}) \dot{x}_m + \frac{1}{12} (\epsilon \gamma^m \theta) (\theta \gamma_m \dot{\theta}) - \frac{1}{12} (\hat{\epsilon} \gamma^m \hat{\theta}) (\hat{\theta} \gamma_m \dot{\hat{\theta}}) \right\}, \quad (2.3)$$

where “|” means “evaluated at the boundary” and we will omit it for brevity in the following. A dot on a field denotes the τ -derivative of the field, while a prime does the σ -derivative. If there are no background fields, the surface term (2.3) can be eliminated by imposing usual boundary conditions for Dp-branes,²

$$x^\mu = 0, \quad \dot{x}^i = 0, \quad \hat{\theta} = \gamma^{1\dots p} \theta, \quad \hat{\lambda} = \gamma^{1\dots p} \lambda, \quad (2.4)$$

and $\mathcal{N} = 1$ supersymmetry condition $\hat{\epsilon} = \gamma^{1\dots p} \epsilon$. These boundary conditions imply that $p = \text{odd}$ for the type IIB string while $p = \text{even}$ for the type IIA string. As usual, x^μ ($\mu = 0, \dots, p$) are Neumann coordinates, while x^i ($i = p + 1, \dots, 9$) are Dirichlet coordinates.

Instead of imposing boundary conditions, we will consider coupling to the background superfields preserving the $\mathcal{N} = 1$ supersymmetry specified by $\hat{\epsilon} = \gamma^{1\dots p} \epsilon$. To preserve

²We must impose the same boundary condition on θ and λ since BRS transformations relate them to each other. These boundary conditions also eliminate the surface term which comes from the BRS transformation of the world-sheet action S_0 . See [29,30] for related topics.

$\mathcal{N} = 1$ supersymmetry, we must introduce a boundary term which eliminates (2.3).

III. $\mathcal{N} = 1$ SUPERSYMMETRY AND BOUNDARY TERM

Here we will introduce a boundary term S_b which leaves $S_0 + S_b$ invariant under the $\mathcal{N} = 1$ supersymmetry. For this purpose, it is convenient to introduce the following objects,

$$\begin{aligned}\theta_{\pm}^{\alpha} &= \frac{1}{\sqrt{2}}(\hat{\theta}^{\alpha} \pm (\gamma^{1\dots p}\theta)^{\alpha}), & d_{\alpha}^{\pm} &= \sqrt{2}(\hat{d}_{\alpha} \pm (\gamma^{1\dots p}d)_{\alpha}), \\ \lambda_{\pm}^{\alpha} &= \frac{1}{\sqrt{2}}(\hat{\lambda}^{\alpha} \pm (\gamma^{1\dots p}\lambda)^{\alpha}), & \omega_{\alpha}^{\pm} &= \sqrt{2}(\hat{\omega}_{\alpha} \pm (\gamma^{1\dots p}\omega)_{\alpha}),\end{aligned}\quad (3.1)$$

where $d_{\alpha} = p_{\alpha} - \frac{1}{2}\partial x^m(\gamma_m\theta)_{\alpha} - \frac{1}{8}(\theta\gamma^m\partial\theta)(\gamma_m\theta)_{\alpha}$ and $\hat{d}_{\alpha} = \hat{p}_{\alpha} - \frac{1}{2}\bar{\partial}x^m(\gamma_m\hat{\theta})_{\alpha} - \frac{1}{8}(\hat{\theta}\gamma^m\bar{\partial}\hat{\theta})(\gamma_m\hat{\theta})_{\alpha}$ are invariant under the ϵ - and $\hat{\epsilon}$ -supersymmetry in (2.2), respectively. By using

these variables, the $\mathcal{N} = 1$ supersymmetry transformations specified by $\hat{\epsilon} = \gamma^{1\dots p}\epsilon$ are represented as

$$\begin{aligned}\delta_{\eta}\theta_{+}^{\alpha} &= \eta^{\alpha}, & \delta_{\eta}\theta_{-}^{\alpha} &= 0, & \delta_{\eta}x^{\mu} &= \frac{1}{2}\theta_{+}\gamma^{\mu}\eta, \\ \delta_{\eta}x^i &= \frac{1}{2}\theta_{-}\gamma^i\eta, & \delta_{\eta}\lambda_{\pm}^{\alpha} &= \delta_{\eta}\omega_{\pm}^{\alpha} = 0,\end{aligned}\quad (3.2)$$

where we introduced η by $\eta \equiv \frac{1}{\sqrt{2}}(\hat{\epsilon} + \gamma^{1\dots p}\epsilon)$. The $\mathcal{N} = 1$ supersymmetry transformation of S_0 is found to be

$$\begin{aligned}\delta_{\eta}S_0 &= -\frac{1}{2\pi\alpha'}\int d\tau\left\{\frac{1}{2}(\eta\gamma^{\mu}\theta_{-})\dot{x}_{\mu} + \frac{1}{2}(\eta\gamma^i\theta_{+})\dot{x}_i\right. \\ &\quad \left.+ \frac{1}{8}(\eta\gamma^m\theta_{+})(\theta_{-}\gamma_m\dot{\theta}_{+}) + \frac{1}{24}(\eta\gamma^m\theta_{-})(\theta_{-}\gamma_m\dot{\theta}_{-})\right\},\end{aligned}\quad (3.3)$$

where we have used the Fierz identity. The boundary term S_b we found is

$$\begin{aligned}S_b &= \frac{1}{2\pi\alpha'}\int d\tau\left\{\frac{1}{2}\Pi_{+}^{\mu}(\theta_{+}\gamma_{\mu}\theta_{-}) - \frac{1}{2}y^i(\theta_{+}\gamma_i\dot{\theta}_{+}) - \frac{1}{8}(\theta_{+}\gamma^{\mu}\theta_{-})(\theta_{+}\gamma_{\mu}\dot{\theta}_{+}) + \frac{1}{8}(\theta_{+}\gamma^i\theta_{-})(\theta_{+}\gamma_i\dot{\theta}_{+})\right. \\ &\quad \left.+ \frac{1}{24}(\theta_{+}\gamma^m\theta_{-})(\theta_{-}\gamma_m\dot{\theta}_{-}) + \frac{1}{2}c_1\Delta_{\alpha}^{+}\theta_{-}^{\alpha} + \frac{1}{2}c_2\omega_{\alpha}^{+}\lambda_{-}^{\alpha} + y_i\tilde{\Pi}_{+}^i\right\},\end{aligned}\quad (3.4)$$

where c_1 and c_2 are constants. We have introduced the following,

$$\begin{aligned}\Pi_{+}^{\mu} &= \frac{1}{2}(\hat{\Pi}^{\mu} + \Pi^{\mu}) - \frac{1}{2}(\theta_{-}\gamma^{\mu}\dot{\theta}_{-}), & \Pi_{-}^i &= \frac{1}{2}(\hat{\Pi}^i + \Pi^i) - \frac{1}{2}(\theta_{-}\gamma^i\dot{\theta}_{+}), \\ \tilde{\Pi}_{-}^{\mu} &= \frac{1}{2}(\hat{\Pi}^{\mu} - \Pi^{\mu}) - \frac{1}{2}(\theta_{-}\gamma^{\mu}\dot{\theta}_{+}), & \tilde{\Pi}_{+}^i &= \frac{1}{2}(\hat{\Pi}^i - \Pi^i) - \frac{1}{2}(\theta_{-}\gamma^i\dot{\theta}_{-}), \\ y^i &= x^i + \frac{1}{2}(\theta_{+}\gamma^i\theta_{-}), \\ \Delta_{\alpha}^{+} &= d_{\alpha}^{+} + \frac{1}{2}(\gamma^{\mu}\theta_{-})_{\alpha}(\hat{\Pi}_{\mu} - \Pi_{\mu}) + \frac{1}{2}(\gamma^i\theta_{-})_{\alpha}(\hat{\Pi}_i + \Pi_i),\end{aligned}\quad (3.5)$$

where $\Pi^m = \partial x^m + \frac{1}{2}\theta\gamma^m\partial\theta$ and $\hat{\Pi}^m = \bar{\partial}x^m + \frac{1}{2}\hat{\theta}\gamma^m\bar{\partial}\hat{\theta}$ are ϵ - and $\hat{\epsilon}$ -supersymmetry invariants, respectively. Objects in (3.5) are invariant under the $\mathcal{N} = 1$ supersymmetry. To show this, we have to treat objects like θ'_{\pm} at the boundary. For this, we require that at the boundary

$$\theta'_{\pm} = -\dot{\theta}_{\mp}, \quad \lambda'_{\pm} = -\dot{\lambda}_{\mp}. \quad (3.6)$$

These are consistent with the bulk equations of motion $\bar{\partial}\theta^{\alpha} = \partial\hat{\theta}^{\alpha} = \bar{\partial}\lambda^{\alpha} = \partial\hat{\lambda}^{\alpha} = 0$. It is shown that this choice leads to DBI equations in this paper. We also note that the last three terms in (3.4) are invariant under the $\mathcal{N} = 1$ supersymmetry separately. This implies that they are not determined from the $\mathcal{N} = 1$ supersymmetry. It is worth

noting that (3.4) cannot be extracted as a dimensional reduction of the one for the D9-brane.

A. BRS symmetry

We shall show that the last term $y_i\tilde{\Pi}_{+}^i$ in (3.4) is required by the BRS invariance of $S_0 + S_b$, when there is no background superfield coupling.

The action (2.1) is invariant under a pair of BRS variations, say δ_1 and δ_2 . In the presence of the boundary, these BRS variations must satisfy $\delta_1 = \delta_2$ at the boundary. This implies that the BRS transformations $\delta_Q = \delta_1 + \delta_2$ remain unbroken in the presence of the boundary,

$$\begin{aligned}
\delta_Q \theta_{\pm}^{\alpha} &= \lambda_{\pm}^{\alpha}, & \delta_Q \lambda_{\pm}^{\alpha} &= 0, & \delta_Q \omega_{\alpha}^{\pm} &= d_{\alpha}^{\pm}, \\
\delta_Q x^{\mu} &= \frac{1}{2} \lambda_{+} \gamma^{\mu} \theta_{+} + \frac{1}{2} \lambda_{-} \gamma^{\mu} \theta_{-}, & \delta_Q x^i &= \frac{1}{2} \lambda_{+} \gamma^i \theta_{-} + \frac{1}{2} \lambda_{-} \gamma^i \theta_{+}, & \delta_Q y^i &= \lambda_{+} \gamma^i \theta_{-}, \\
\delta_Q \Pi_{+}^{\mu} &= \lambda_{+} \gamma^{\mu} \dot{\theta}_{+} + \frac{1}{2} \lambda_{-} \gamma^{\mu} \dot{\theta}_{-} + \frac{1}{2} \dot{\lambda}_{-} \gamma^{\mu} \theta_{-}, & \delta_Q \Pi_{-}^i &= \lambda_{+} \gamma^i \dot{\theta}_{-} + \frac{1}{2} \lambda_{-} \gamma^i \dot{\theta}_{+} + \frac{1}{2} \dot{\lambda}_{+} \gamma^i \theta_{-}, \\
\delta_Q \tilde{\Pi}_{+}^{\mu} &= \lambda_{+} \gamma^{\mu} \dot{\theta}_{-} + \frac{1}{2} \lambda_{-} \gamma^{\mu} \dot{\theta}_{+} + \frac{1}{2} \dot{\lambda}_{+} \gamma^{\mu} \theta_{-}, & \delta_Q \tilde{\Pi}_{+}^i &= \lambda_{+} \gamma^i \dot{\theta}_{+} + \frac{1}{2} \lambda_{-} \gamma^i \dot{\theta}_{-} + \frac{1}{2} \dot{\lambda}_{-} \gamma^i \theta_{-}, \\
\delta_Q \Delta_{\alpha}^{+} &= -2(\gamma_{\mu} \lambda_{+})_{\alpha} \Pi_{+}^{\mu} - 2(\gamma_i \lambda_{+})_{\alpha} \tilde{\Pi}_{+}^i - (\gamma_{\mu} \lambda_{-})_{\alpha} \tilde{\Pi}_{-}^{\mu} - (\gamma_i \lambda_{-})_{\alpha} \Pi_{-}^i \\
&\quad - (\gamma^m \dot{\theta}_{-})_{\alpha} (\lambda_{+} \gamma_m \theta_{-}) - (\gamma^m \theta_{-})_{\alpha} (\lambda_{-} \gamma_m \dot{\theta}_{+}) - \frac{1}{2} (\gamma^m \lambda_{-})_{\alpha} (\theta_{-} \gamma_m \dot{\theta}_{+}).
\end{aligned} \tag{3.7}$$

Again, we find the world-sheet action S_0 is BRS invariant $\delta_Q S_0 = 0$ up to a surface term, and satisfies

$$\begin{aligned}
\delta_Q (S_0 + S_b) &= \frac{1}{2\pi\alpha'} \int d\tau \left\{ (1 - c_1) \Pi_{+}^{\mu} (\lambda_{+} \gamma_{\mu} \theta_{-}) - \frac{1}{2} (c_1 + c_2) \Pi_{-}^i (\lambda_{-} \gamma_i \theta_{-}) \right. \\
&\quad - \frac{1}{2} (c_1 + c_2) \tilde{\Pi}_{-}^{\mu} (\lambda_{-} \gamma_{\mu} \theta_{-}) + (1 - c_1) \tilde{\Pi}_{+}^i (\lambda_{+} \gamma_i \theta_{-}) \\
&\quad + \frac{1}{2} (c_2 - c_1) \Delta_{\beta}^{+} \lambda_{-}^{\beta} + \left(-\frac{1}{3} + \frac{c_1 + c_2}{4} \right) (\lambda_{-} \gamma^m \theta_{-}) (\dot{\theta}_{+} \gamma_m \theta_{-}) \\
&\quad \left. + \frac{1}{2} \left(\frac{1}{3} - c_1 \right) (\lambda_{+} \gamma^m \theta_{-}) (\theta_{-} \gamma_m \dot{\theta}_{-}) \right\}.
\end{aligned} \tag{3.8}$$

Let us assume that there are no background fields. In this case, the (3.8) must be eliminated by the usual boundary conditions $\theta_{\pm}^{\alpha} = \lambda_{\pm}^{\alpha} = 0$. It is obvious to see that these boundary conditions eliminate (3.8) as expected. It should be noted that this happens only when we include the term $y_i \tilde{\Pi}_{+}^i$ in (3.4).

Finally we comment on y_i . Remarkably, the BRS transformation of $S_0 + S_b$, at the boundary, is independent of y_i . More generally, we confirm $\delta(S_0 + S_b)/\delta y_i = 0$ in Appendix C. This strongly suggests that y_i should represent the position of the Dp -brane.

IV. SUPERSYMMETRIC DBI EQUATIONS OF MOTION

In this section, we will give the background coupling V in terms of superfields on a Dp -brane. Examining the BRS variation of $S_0 + S_b + V$, we obtain supersymmetric DBI equations of motion on the Dp -brane.

A. Background superfield coupling for Dp -branes

In Appendix A, we define the ten-dimensional $\mathcal{N} = 1$ superfield $A_M = (A_m, A_{\alpha})$. We introduce background superfields on a Dp -brane as a dimensional reduction of A_M : $A_m = (A_{\mu}(x^{\mu}, \theta_{+}), A_i(x^{\mu}, \theta_{+}))$ and $A_{\alpha} = A_{\alpha}(x^{\mu}, \theta_{+})$. Obviously they are invariant under the $\mathcal{N} = 1$ supersymmetry. Similarly we introduce $\mathcal{W}^{\alpha} = \mathcal{W}^{\alpha}(x^{\mu}, \theta_{+})$

and $F_{mn} = F_{mn}(x^{\mu}, \theta_{+})$. We use the ten-dimensional Majorana-Weyl spinor notation throughout this paper. This means that we are considering the DBI equations with 16 supersymmetries, for example $\mathcal{N} = 4$ supersymmetric DBI equations on a D3-brane.

The background coupling V used in [24] is regarded as an extension of the vertex operator of the open pure spinor superstring. We give a brief review of the vertex operator in Appendix B.

The background coupling V we introduce is

$$\begin{aligned}
V &= \frac{1}{2\pi\alpha'} \int d\tau \left\{ \dot{\theta}_{+}^{\alpha} A_{\alpha}(x^{\mu}, \theta_{+}) + \Pi_{+}^{\mu} A_{\mu}(x^{\mu}, \theta_{+}) \right. \\
&\quad + \tilde{\Pi}_{+}^i A_i(x^{\mu}, \theta_{+}) + \frac{1}{2} \Delta_{\alpha}^{+} \mathcal{W}^{\alpha}(x^{\mu}, \theta_{+}) \\
&\quad \left. + \frac{1}{4} N_{+} \mathcal{F}(x^{\mu}, \theta_{+}) \right\},
\end{aligned} \tag{4.1}$$

where

$$\begin{aligned}
(N_{+})_{\alpha}^{\beta} &= \frac{1}{2} \omega_{\alpha}^{+} \lambda_{+}^{\beta}, \\
\mathcal{F}_{\beta}^{\alpha} &= \delta_{\beta}^{\alpha} \mathcal{F}^{(0)} + (\gamma^{mn})_{\beta}^{\alpha} \mathcal{F}_{mn}^{(2)} + (\gamma^{mnpq})_{\beta}^{\alpha} \mathcal{F}_{mnpq}^{(4)}.
\end{aligned} \tag{4.2}$$

Note that $\mathcal{F}^{(0)}$, $\mathcal{F}_{mn}^{(2)}$ and $\mathcal{F}_{mnpq}^{(4)}$ are some possible products of any number of vector field strengths

F_{mn} ,³ which is consistent with analysis for D-brane boundary states [26] from the viewpoint of the pure spinor closed superstring. Needless to say, the V is invariant under the $\mathcal{N} = 1$ supersymmetry. Since we have made the factor $1/(2\pi\alpha')$ manifest in V , dimensions of these superfields differ from conventional ones. In this sense, we assign dimensions to $[A_\alpha]$, $[A_m]$, $[\mathcal{W}^\alpha]$ and $[F_{mn}]$ as $-\frac{3}{2}$, -1 , $-\frac{1}{2}$ and 0 , respectively.

B. DBI equations from BRS symmetry

In this subsection, we will add the background superfield coupling V in (IV A) to the action $S_0 + S_b$ and then require that the BRS variation $\delta_Q(S_0 + S_b + V)$ vanishes. This requirement leads to boundary conditions on spacetime spinors and conditions on background superfields. The latter is found to be supersymmetric DBI equations of motion for them.

We find that the BRS variation $\delta_Q V$ may be expressed as

$$\begin{aligned} \delta_Q V = & \frac{1}{2\pi\alpha'} \int d\tau \left\{ \Pi_+^\mu \left[-\lambda_+^\alpha \partial_\mu A_\alpha + \lambda_+^\alpha D_\alpha A_\mu + \frac{1}{2} (\lambda_- \gamma^n \theta_-) (\partial_n A_\mu - \partial_\mu A_n) - (\lambda_+ \gamma_\mu \mathcal{W}) \right] \right. \\ & + \Pi_-^i \left[-\frac{1}{2} (\lambda_- \gamma_i \mathcal{W}) - \frac{1}{8} (\gamma_i \theta_-)_\alpha \lambda_+^\beta \mathcal{F}^\alpha{}_\beta \right] + \tilde{\Pi}^\mu \left[-\frac{1}{2} (\lambda_- \gamma_\mu \mathcal{W}) - \frac{1}{8} (\gamma_\mu \theta_-)_\alpha \lambda_+^\beta \mathcal{F}^\alpha{}_\beta \right] \\ & + \tilde{\Pi}_+^i \left[-(\lambda_+ \gamma_i \mathcal{W}) + \lambda_+^\alpha D_\alpha A_i + \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu A_i \right] + \frac{1}{2} \Delta_\beta^+ \left[-\lambda_+^\alpha D_\alpha \mathcal{W}^\beta - \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu \mathcal{W}^\beta + \frac{1}{4} \lambda_+^\alpha \mathcal{F}^\beta{}_\alpha \right] \\ & + \frac{1}{4} N_{+\beta\gamma} \left[\lambda_+^\alpha D_\alpha \mathcal{F}^\beta{}_\gamma + \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu \mathcal{F}^\beta{}_\gamma \right] + \dot{\theta}_+^\beta \left[-\lambda_+^\alpha D_\beta A_\alpha - \lambda_+^\alpha D_\alpha A_\beta - \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu A_\beta + (\gamma^m \lambda_+)_{\beta} A_m \right. \\ & + \frac{1}{2} (\lambda_- \gamma^m \theta_-) D_\beta A_m + \frac{1}{2} (\gamma^m \lambda_-)_\beta (\theta_- \gamma_m \mathcal{W}) + \frac{1}{4} (\gamma^m \theta_-)_\beta (\lambda_- \gamma_m \mathcal{W}) + \frac{1}{16} (\gamma^m \theta_-)_\beta (\gamma_m \theta_-)_\gamma \lambda_+^\alpha \mathcal{F}^\gamma{}_\alpha \left. \right] \\ & \left. + \dot{\theta}_-^\beta \left[-\frac{1}{2} (\lambda_+ \gamma^m \theta_-) (\gamma_m \mathcal{W})_\beta \right] \right\}. \end{aligned} \quad (4.4)$$

Note that the supercovariant derivative on the Dp -brane is defined by

$$D_\alpha = \frac{\partial}{\partial \theta_+^\alpha} + \frac{1}{2} (\gamma^\mu \theta_+)_\alpha \partial_\mu. \quad (4.5)$$

Gathering (3.8) and (4.4) together, we obtain the BRS variation of $S_0 + S_b + V$ as

$$\delta_Q(S_0 + S_b + V) = \frac{1}{2\pi\alpha'} \int d\tau \left\{ \Pi_+^\mu X_\mu + \tilde{\Pi}_+^i X_i + \Pi_-^i Y_i + \tilde{\Pi}_-^\mu Y_\mu - \frac{1}{2} \Delta_\beta^+ \Lambda^\beta + \frac{1}{4} N_{+\beta}{}^\alpha Z_\alpha^\beta + \dot{\theta}_+^\alpha \Theta_\alpha^+ + \dot{\theta}_-^\alpha \Theta_\alpha^- \right\}, \quad (4.6)$$

where X_m , Y_m , Λ^β , Z_α^β and Θ_α^\pm are given as follows:

$$X_m \equiv (1 - c_1) (\lambda_+ \gamma_m \theta_-) - \lambda_+^\alpha \partial_m A_\alpha + \lambda_+^\alpha D_\alpha A_m - \frac{1}{2} (\lambda_- \gamma^m \theta_-) (\partial_m A_n - \partial_n A_m) - (\lambda_+ \gamma_m \mathcal{W}), \quad (4.7)$$

$$Y_m \equiv -\frac{1}{2} (c_1 + c_2) (\lambda_- \gamma_m \theta_-) - \frac{1}{2} (\lambda_- \gamma_m \mathcal{W}) - \frac{1}{8} (\gamma_m \theta_-)_\alpha \lambda_+^\beta \mathcal{F}^\alpha{}_\beta, \quad (4.8)$$

$$\Lambda^\beta \equiv (c_1 - c_2) \lambda_-^\beta + \lambda_+^\alpha D_\alpha \mathcal{W}^\beta + \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu \mathcal{W}^\beta - \frac{1}{4} \lambda_+^\alpha \mathcal{F}^\beta{}_\alpha, \quad (4.9)$$

$$Z_\alpha^\beta \equiv \lambda_+^\gamma D_\gamma \mathcal{F}^\beta{}_\alpha + \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu \mathcal{F}^\beta{}_\alpha, \quad (4.10)$$

³There are no more higher forms because of the property,

$$\omega_\alpha (\gamma^{m_1 \dots m_{2k}})^\alpha{}_\beta \lambda^\beta = \pm \frac{1}{(10 - 2k)!} (-1)^{k+1} \epsilon^{m_1 \dots m_{2k} n_1 \dots n_{10-2k}} \omega_\alpha (\gamma^{n_1 \dots n_{10-2k}})^\alpha{}_\beta \lambda^\beta, \quad (4.3)$$

where the sign in the right-hand side depends on the chirality of λ .

$$\begin{aligned}
\Theta_\alpha^+ &\equiv \left(-\frac{1}{3} + \frac{c_1 + c_2}{4}\right) (\gamma^m \theta_-)_\alpha (\lambda_- \gamma_m \theta_-) - \lambda_+^\beta (D_\alpha A_\beta + D_\beta A_\alpha) - \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu A_\alpha \\
&+ (\gamma^m \lambda_+)_\alpha A_m + \frac{1}{2} (\lambda_- \gamma^m \theta_-) D_\alpha A_m + \frac{1}{2} (\gamma^m \lambda_-)_\alpha (\theta_- \gamma_m \mathcal{W}) \\
&+ \frac{1}{4} (\gamma^m \theta_-)_\alpha (\lambda_- \gamma_m \mathcal{W}) + \frac{1}{16} (\gamma^m \theta_-)_\alpha (\gamma_m \theta_-)_\gamma \lambda_+^\beta \mathcal{F}^\gamma_\beta,
\end{aligned} \tag{4.11}$$

$$\Theta_\alpha^- \equiv \frac{1}{2} \left(c_1 - \frac{1}{3}\right) (\gamma^m \theta_-)_\alpha (\lambda_+ \gamma_m \theta_-) - \frac{1}{2} (\lambda_+ \gamma^m \theta_-) (\gamma_m \mathcal{W})_\alpha. \tag{4.12}$$

In the following, we will examine conditions that each term in (4.6) vanishes.

To achieve our purpose, first, we focus on the term $\tilde{\Pi}_+^i X_i$ in (4.6) which takes the form

$$\tilde{\Pi}_+^i [-\lambda_+^\alpha \gamma_{i\alpha\beta} (c_1 \theta_-^\beta + \mathcal{W}^\beta) + \delta_Q (y_i + A_i)]. \tag{4.13}$$

Here we assume that $\delta_Q (y_i + A_i) = 0$. This follows from the fact that we fix degrees of freedom for the D-brane position by

$$y_i = -A_i. \tag{4.14}$$

In fact, this identification turns to $y_i = 0$ in the $\alpha' \rightarrow 0$ limit after the scaling $A_i \rightarrow (2\pi\alpha')A_i$. It implies that we consider a D-brane sitting at the origin. As we will see below, the BRS transformation of (4.14) turns into one of the DBI equations and the derivation of (4.14) with respect to the time-coordinate τ also turns into the Dirichlet boundary condition. One may add a constant to the right-hand side of (4.14) to consider a D-brane sitting outside the origin, but this will not affect the DBI equation and the Dirichlet boundary condition as anticipated. In addition, we obtain the boundary condition on θ_- as

$$\theta_-^\beta = -\frac{1}{c_1} \mathcal{W}^\beta. \tag{4.15}$$

This eliminates θ_-^α from (4.6) completely. Hereafter we understand θ_-^α as (4.15). Note that (4.15) also leads to

$$\dot{\theta}_-^\beta = -\frac{1}{c_1} (\Pi_+^\mu \partial_\mu \mathcal{W}^\beta + \dot{\theta}_+^\gamma D_\gamma \mathcal{W}^\beta). \tag{4.16}$$

Second, the terms $\Pi_-^i Y_i$ and $\tilde{\Pi}^\mu Y_\mu$ reduce to

$$\Pi_-^m \left[\left(c_2 \lambda_-^\alpha + \frac{1}{4} \lambda_+^\beta \mathcal{F}^\alpha_\beta \right) \frac{1}{c_1} (\gamma_m \mathcal{W})_\alpha \right], \tag{4.17}$$

and imply the boundary condition on λ_- ,

$$\lambda_-^\alpha = -\frac{1}{4c_2} \lambda_+^\beta \mathcal{F}^\alpha_\beta. \tag{4.18}$$

This eliminates λ_-^α from (4.6) completely. Hereafter we understand λ_-^α as (4.18).

Here, it is better to comment on two consequences of the boundary conditions (4.15) and (4.18). First, consider the limit $\alpha' \rightarrow 0$. The limit $\alpha' \rightarrow 0$, after rescaling $A_\alpha \rightarrow (2\pi\alpha')A_\alpha$, $A_m \rightarrow (2\pi\alpha')A_m$, $\mathcal{W}^\alpha \rightarrow (2\pi\alpha')\mathcal{W}^\alpha$ and $F_{mn} \rightarrow (2\pi\alpha')F_{mn}$, turns the boundary conditions (4.15) and (4.18) to the usual boundary conditions $\theta_-^\alpha = \lambda_-^\alpha = 0$. The BRS invariance $\delta_Q (S_0 + S_b + V) = 0$ then implies $\delta_Q V = 0$, since $\delta_Q (S_0 + S_b) = 0$ under these boundary conditions. We can show that $\delta_Q V = 0$ with usual boundary conditions leads to the super-Yang-Mills equations of motion (B9)–(B11) as discussed in Appendix B.

We consider the BRS variation $\delta_Q (y_i + A_i) = 0$. To evaluate it, we note that $\delta_Q A_i = \lambda_+^\alpha D_\alpha A_i + \frac{1}{2} (\lambda_- \gamma^\mu \theta_-) \partial_\mu A_i$. Under the boundary conditions (4.15) and (4.18), the equation $\delta_Q (y_i + A_i) = 0$ is shown to reduce to the following equation:

$$-D_\alpha A_i + \frac{1}{c_1} (\gamma_i \mathcal{W})_\alpha - \frac{1}{8c_1 c_2} \mathcal{F}^\beta_\alpha (\gamma^\mu \mathcal{W})_\beta \partial_\mu A_i = 0. \tag{4.19}$$

This is one of the DBI equations. Furthermore, noting that $\dot{A}_i = \dot{\theta}_+^\alpha D_\alpha A_i + \Pi_+^\mu \partial_\mu A_i$, one finds that the time derivative of (4.14) turns into the Dirichlet boundary condition given in (C11).

Let us return to the subject. Third, the term $\Delta_\beta^+ \Lambda^\beta$ in (4.6) is examined. We see that $\Lambda^\beta = 0$ reduces to

$$\frac{1}{c_1} D_\alpha \mathcal{W}^\beta - \frac{1}{4c_2} \mathcal{F}^\beta_\alpha + \frac{1}{8c_1^2 c_2} \mathcal{F}^\gamma_\alpha (\gamma^\mu \mathcal{W})_\gamma \partial_\mu \mathcal{W}^\beta = 0. \tag{4.20}$$

This is one of the DBI equations on a Dp-brane. This equation ensures that conditions (4.15) and (4.18) are consistent with BRS transformations $\delta_Q \theta_-^\alpha = \lambda_-^\alpha$ and $\delta_Q \lambda_-^\alpha = 0$.

As was done in [24], it is convenient to introduce a covariant derivative \hat{D}_α by

$$\hat{D}_\alpha \equiv D_\alpha + \frac{1}{8c_1c_2} \mathbb{F}^\gamma{}_\alpha (\gamma^\mu \mathcal{W})_\gamma \partial_\mu. \quad (4.21)$$

Applying it to $\frac{1}{c_1} \mathcal{W}^\beta$, we obtain

$$\frac{1}{c_1} \hat{D}_\alpha \mathcal{W}^\beta = \frac{1}{c_1} D_\alpha \mathcal{W}^\beta + \frac{1}{8c_1^2c_2} \mathbb{F}^\gamma{}_\alpha (\gamma^\mu \mathcal{W})_\gamma \partial_\mu \mathcal{W}^\beta = \frac{1}{4c_2} \mathbb{F}^\beta{}_\alpha, \quad (4.22)$$

where in the last equality (4.20) is used. On the other hand, as (4.20) implies

$$\frac{1}{4c_2} \mathbb{F}^\beta{}_\alpha = \frac{1}{c_1} D_\alpha \mathcal{W}^\gamma \left(\delta_\beta^\gamma - \frac{1}{2c_1^2} (\gamma^\mu \mathcal{W})_\beta \partial_\mu \mathcal{W}^\gamma \right)^{-1}, \quad (4.23)$$

\hat{D}_α is expressed as

$$\hat{D}_\alpha = D_\alpha + \frac{1}{2c_1^2} D_\alpha \mathcal{W}^\delta \left(\delta_\gamma^\delta - \frac{1}{2c_1^2} (\gamma^\mu \mathcal{W})_\gamma \partial_\mu \mathcal{W}^\delta \right)^{-1} (\gamma^\mu \mathcal{W})_\gamma \partial_\mu. \quad (4.24)$$

It follows that it satisfies the following anticommutation relation:

$$\begin{aligned} \{\hat{D}_\alpha, \hat{D}_\beta\} &= \left(\gamma_{\alpha\beta}^\mu + \frac{1}{16c_2^2} \mathbb{F}^\gamma{}_\alpha \mathbb{F}^\delta{}_\beta \gamma_{\gamma\delta}^\mu \right) \hat{\partial}_\mu, \\ \hat{\partial}_\mu &\equiv \partial_\mu + \frac{1}{2c_1^2} \partial_\mu \mathcal{W}^\alpha \left(\delta_\beta^\alpha - \frac{1}{2c_1^2} \gamma_{\beta\gamma}^\nu \mathcal{W}^\gamma \partial_\nu \mathcal{W}^\alpha \right)^{-1} \\ &\quad \times (\gamma^\rho \mathcal{W})_\beta \partial_\rho. \end{aligned} \quad (4.25)$$

Fourth, the term $(N_+)_\beta^\alpha Z^\beta{}_\alpha$ in (4.6) is examined. Using (4.22) and (4.25), it turns to

$$\begin{aligned} \lambda_+^\alpha \lambda_+^\gamma \left(\frac{1}{c_2} \hat{D}_\alpha \mathbb{F}^\beta{}_\gamma \right) &= \lambda_+^\alpha \lambda_+^\gamma \left(\frac{4}{c_1} \hat{D}_\alpha \hat{D}_\gamma \mathcal{W}^\beta \right) \\ &= \lambda_+^\alpha \lambda_+^\gamma \left(\gamma_{\alpha\gamma}^\mu + \frac{1}{16c_2^2} \mathbb{F}^\delta{}_\alpha \mathbb{F}^\eta{}_\gamma \gamma_{\delta\eta}^\mu \right) \\ &\quad \times \frac{2}{c_1} \hat{\partial}_\mu \mathcal{W}^\beta, \end{aligned} \quad (4.26)$$

which vanishes due to the pure spinor constraint $\lambda_+ \gamma^\mu \lambda_+ + \lambda_- \gamma^\mu \lambda_- = 0$.

Fifth, we consider terms including Π_+^μ in (4.6), $\Pi_+^\mu X_\mu - \frac{1}{c_1} \Pi_+^\mu \partial_\mu \mathcal{W}^\alpha \Theta_\alpha^-$, where the second term comes from (4.16). It is straightforward to see that it is eliminated by

$$\begin{aligned} \partial_\mu A_\alpha - D_\alpha A_\mu + \frac{1}{c_1} (\gamma_\mu \mathcal{W})_\alpha + \frac{1}{6c_1^3} (\gamma^n \mathcal{W})_\alpha (\mathcal{W} \gamma_n \partial_\mu \mathcal{W}) \\ + \frac{1}{8c_1c_2} \mathbb{F}^\beta{}_\alpha (\gamma^n \mathcal{W})_\beta (\partial_\mu A_n - \partial_n A_\mu) = 0, \end{aligned} \quad (4.27)$$

which is one of the DBI equations. Combining it with (4.19), we obtain

$$\begin{aligned} \partial_m A_\alpha - D_\alpha A_m + \frac{1}{c_1} (\gamma_m \mathcal{W})_\alpha + \frac{1}{6c_1^3} (\gamma^n \mathcal{W})_\alpha (\mathcal{W} \gamma_n \partial_m \mathcal{W}) \\ + \frac{1}{8c_1c_2} \mathbb{F}^\beta{}_\alpha (\gamma^n \mathcal{W})_\beta (\partial_m A_n - \partial_n A_m) = 0. \end{aligned} \quad (4.28)$$

Finally, we consider terms including $\hat{\theta}_+^\alpha$ in (4.6), $\hat{\theta}_+^\alpha \Theta_\alpha^+ - \frac{1}{c_1} \hat{\theta}_+^\beta D_\beta \mathcal{W}^\alpha \Theta_\alpha^-$, where the second term comes from (4.16). These terms are eliminated by

$$\begin{aligned} -D_\alpha A_\beta - D_\beta A_\alpha + \gamma_{\alpha\beta}^m A_m - \frac{1}{6c_1^3} (\gamma^m \mathcal{W})_\alpha (\mathcal{W} \gamma_m D_\beta \mathcal{W}) \\ + \frac{1}{12c_1^2c_2} \mathbb{F}^\gamma{}_\alpha (\gamma^m \mathcal{W})_\beta (\gamma_m \mathcal{W})_\gamma \\ - \frac{1}{8c_1c_2} \mathbb{F}^\gamma{}_\alpha (\gamma^m \mathcal{W})_\gamma (\partial_m A_\beta - D_\beta A_m) = 0. \end{aligned} \quad (4.29)$$

By eliminating $\partial_m A_\beta - D_\beta A_m$ by (4.28), it reduces to

$$\begin{aligned} -D_\alpha A_\beta - D_\beta A_\alpha + \gamma_{\alpha\beta}^m A_m - \frac{1}{6c_1^3} (\gamma^m \mathcal{W})_\alpha (\mathcal{W} \gamma_m D_\beta \mathcal{W}) \\ + \frac{1}{6c_1^2} (\gamma^m \mathcal{W})_\beta (\gamma_m \mathcal{W})_\gamma \\ \times \left\{ -\frac{1}{4c_2} \mathbb{F}^\gamma{}_\alpha + \frac{1}{8c_1^2c_2} \mathbb{F}^\delta{}_\alpha (\gamma^n \mathcal{W})_\delta \partial_n \mathcal{W}^\gamma \right\} \\ + \frac{1}{64c_1^2c_2^2} \mathbb{F}^\gamma{}_\alpha \mathbb{F}^\delta{}_\beta (\gamma^m \mathcal{W})_\gamma (\gamma^n \mathcal{W})_\delta (\partial_m A_n - \partial_n A_m) = 0. \end{aligned} \quad (4.30)$$

Finally substituting (4.20) into the expression in the curly braces in (4.30), we obtain

$$\begin{aligned} -D_\alpha A_\beta - D_\beta A_\alpha + \gamma_{\alpha\beta}^m A_m - \frac{1}{6c_1^3} (\gamma^m \mathcal{W})_\alpha (\mathcal{W} \gamma_m D_\beta \mathcal{W}) \\ - \frac{1}{6c_1^3} (\gamma^m \mathcal{W})_\beta (\mathcal{W} \gamma_m D_\alpha \mathcal{W}) \\ + \frac{1}{64c_1^2c_2^2} \mathbb{F}^\gamma{}_\alpha \mathbb{F}^\delta{}_\beta (\gamma^m \mathcal{W})_\gamma (\gamma^n \mathcal{W})_\delta (\partial_m A_n - \partial_n A_m) = 0. \end{aligned} \quad (4.31)$$

As a result, we have obtained not only boundary conditions (4.15) and (4.18), but also independent equations for background superfields (4.28), (4.31) and (4.20) which eliminates (4.6). We note that c_1 and c_2 can be absorbed into redefinitions of \mathcal{W}^α and $\mathbb{F}^\beta{}_\alpha$ as $\frac{1}{c_1} \mathcal{W}^\alpha \rightarrow \mathcal{W}^\alpha$

and $\frac{1}{c_2} \mathbb{F}^\beta_\alpha \rightarrow \mathbb{F}^\beta_\alpha$. So we will set $c_1 = c_2 = 1$ without loss of generality.⁴

Summarizing, we have obtained supersymmetric DBI equations of motion on a Dp -brane:

$$\begin{aligned} \partial_m A_\alpha - D_\alpha A_m + (\gamma_m \mathcal{W})_\alpha + \frac{1}{6} (\gamma^n \mathcal{W})_\alpha (\mathcal{W} \gamma_n \partial_m \mathcal{W}) \\ + \frac{1}{8} \mathbb{F}^\beta_\alpha (\gamma^n \mathcal{W})_\beta (\partial_m A_n - \partial_n A_m) = 0, \end{aligned} \quad (4.32)$$

$$\begin{aligned} D_\alpha A_\beta + D_\beta A_\alpha - \gamma_{\alpha\beta}^m A_m + \frac{1}{6} (\gamma^m \mathcal{W})_\alpha (\mathcal{W} \gamma_m D_\beta \mathcal{W}) \\ + \frac{1}{6} (\gamma^m \mathcal{W})_\beta (\mathcal{W} \gamma_m D_\alpha \mathcal{W}) \\ - \frac{1}{64} \mathbb{F}^\gamma_\alpha \mathbb{F}^\delta_\beta (\gamma^m \mathcal{W})_\gamma (\gamma^n \mathcal{W})_\delta (\partial_m A_n - \partial_n A_m) = 0, \end{aligned} \quad (4.33)$$

$$D_\alpha \mathcal{W}^\beta - \frac{1}{4} \mathbb{F}^\beta_\alpha + \frac{1}{8} \mathbb{F}^\gamma_\alpha (\gamma^\mu \mathcal{W})_\gamma \partial_\mu \mathcal{W}^\beta = 0. \quad (4.34)$$

In the last equation, the index μ may be replaced with m because $\partial_i \mathcal{W}^\beta = 0$. Now it is manifest that our DBI equations on a Dp -brane can be expressed in a ten-dimensional covariant fashion. In other words, our result coincides with the dimensional reduction of those for a D9-brane, though the ten-dimensional covariance was absent in the beginning of our analysis.

V. SUMMARY AND DISCUSSIONS

We have examined the BRS invariance of the open pure spinor superstring in the presence of background superfields on a Dp -brane. It was shown that the BRS invariance leads not only to boundary conditions on the spacetime spinors, but also to supersymmetric DBI equations of motion for the background superfields on a Dp -brane. These DBI equations precisely coincide with those obtained by a dimensional reduction of the supersymmetric DBI equations for the Abelian D9-brane given in [24,25].

We have introduced the boundary term S_b and the background coupling V . Both are determined by the BRS symmetry. In fact, S_b was shown to satisfy $\delta_Q(S_0 + S_b) = 0$, when we take the limit $\alpha' \rightarrow 0$ and turn off the background couplings. As for V , we have shown that the conditions for $\delta_Q(S_0 + S_b + V) = 0$ reduce to the dimensional reduction of the super-Yang-Mills equations when $\alpha' \rightarrow 0$. In fact, taking the limit $\alpha' \rightarrow 0$, after rescaling $A_\alpha \rightarrow (2\pi\alpha')A_\alpha$, $A_m \rightarrow (2\pi\alpha')A_m$, $\mathcal{W}^\alpha \rightarrow (2\pi\alpha')\mathcal{W}^\alpha$ and $F_{mn} \rightarrow (2\pi\alpha')F_{mn}$, the DBI equations (4.32)–(4.34) reduce to the super-Yang-Mills equations of motion (B9)–(B11) with an appropriate dimensional reduction.

⁴If we construct the κ -invariant boundary term which cancels out an $\mathcal{N} = 1$ supersymmetry variation of the Green-Schwarz action and turn it into the BRS-invariant boundary term like (3.4) by the method used in [31] (see also Sec. IV.1 in [32]), it must be shown $c_1 = c_2 = 1$.

We note that the ten-dimensional Lorentz covariance is manifestly broken by the boundary term S_b as well as the background coupling V . However the obtained DBI equations can be expressed in a covariant form. This implies that our result is consistent with that for a D9-brane.

We expect that we can extend our result so that the BRS invariance should lead to supersymmetric non-Abelian DBI equations of motion on a Dp -brane. We would like to report this issue in the near future [33].

As an alternative to our study, non-Abelian deformations of the maximally supersymmetric Yang-Mills theory can be specified based on spinorial cohomology [34], which may be closely related to the pure spinor fields in ten- and eleven-dimensional spacetime [35–37]. The structure of higher-derivative invariants in the maximally supersymmetric Yang-Mills theories are studied in [38]. Moreover, in [39,40] the pure spinor superspace formalism is developed, which contains not only (minimal) pure spinor variables but also nonminimal pure spinor variables [41]. This enables us to construct the BRS invariant action for the ten-dimensional supersymmetric DBI theory. Recently, this off-shell action is studied further in [42,43]. It is interesting to pursue these issues from the open string point of view.

On the other hand, the classical BRS invariance of a closed pure spinor superstring in a curved background is shown to imply that the background fields satisfy full nonlinear equations of motion for the type II supergravity [44]. This is similar to the result for the classical κ -invariance of a closed Green-Schwarz superstring [45]. Moreover, recently in [46] the classical κ -invariance also leads to the generalized type II supergravity equations of motion⁵ whose solutions originally have been found out in the context of integrable deformations of $AdS_5 \times S^5$ sigma models [48]. It is also interesting to consider whether the generalization of DBI equations can be derived analogously from the κ or BRS invariance of an open superstring.

An immediate task is to clarify contribution of the dilaton superfield to Bianchi identities. In that case we need to investigate closely the DBI equation corresponding to $I_{mna} = 0$ in the super-Yang-Mills theory as we see in Appendix A. This equation is also useful to confirm that our result agrees with the one which comes from the bosonic part of the DBI action.

Finally, it is interesting for us to calculate quantum higher-derivative corrections to our result by analyzing the quantum BRS invariance of the open pure spinor superstring.

APPENDIX A: TEN-DIMENSIONAL $\mathcal{N} = 1$ SUPER-YANG-MILLS SPACE

We will review the ten-dimensional $\mathcal{N} = 1$ super-Yang-Mills theory [49]. Introducing a superconnection one-form $A = E^M A_M$, where E^M are supervielbeins and $A_M = (A_m, A_\alpha)$ are superconnections, we define the gauge supercovariant derivative ∇_M :

$$\nabla_m = \partial_m + A_m, \quad \nabla_\alpha = D_\alpha + A_\alpha, \quad (\text{A1})$$

where D_α is the supercovariant derivative defined by

$$D_\alpha = \frac{\partial}{\partial \theta^\alpha} + \frac{1}{2}(\gamma^m \theta)_\alpha \partial_m, \quad (\text{A2})$$

which satisfies $\{D_\alpha, D_\beta\} = \gamma_{\alpha\beta}^m \partial_m$. The field strengths F_{MN} are defined by

$$\{\nabla_M, \nabla_N\} = T_{MN}{}^R \nabla_R + F_{MN}, \quad (\text{A3})$$

where $T_{MN}{}^R$ are flat torsion tensors whose components are fixed to zero except for $T_{\alpha\beta}^m = \gamma_{\alpha\beta}^m$. According to this definition, these field strengths are invariant under the gauge transformations with a superfield parameter Ω :

$$\delta A_m = \partial_m \Omega, \quad \delta A_\alpha = D_\alpha \Omega. \quad (\text{A4})$$

For the on-shell super-Yang-Mills theory, we might adopt a constraint [35] (see also [36]),

$$F_{\alpha\beta} = 0, \quad (\text{A5})$$

which implies

$$D_\alpha A_\beta + D_\beta A_\alpha + \{A_\alpha, A_\beta\} = \gamma_{\alpha\beta}^m A_m. \quad (\text{A6})$$

If we consider a dimensional reduction to four dimensions, we see that this constraint reduces to the one in the four-dimensional $\mathcal{N} = 4$ super-Yang-Mills theory [50].

In the following, let us solve the Bianchi identities represented as

$$\begin{aligned} I_{MNR} &= (-1)^{R(M+N)} \nabla_R F_{MN} - T_{MN}{}^S F_{SR} \\ &+ (-1)^{M(R+N)} \nabla_N F_{RM} - (-1)^{R(M+N)} T_{RM}{}^S F_{SN} \\ &+ \nabla_M F_{NR} - (-1)^{M(N+R)} T_{NR}{}^S F_{SM}. \end{aligned} \quad (\text{A7})$$

The first identity $I_{\alpha\beta\gamma} = 0$ implies

$$-\gamma_{\alpha\beta}^m F_{m\gamma} - \gamma_{\gamma\alpha}^m F_{m\beta} - \gamma_{\beta\gamma}^m F_{m\alpha} = 0. \quad (\text{A8})$$

Thanks to the Fierz identity, we find that the field strength $F_{m\alpha}$ must take the form of

$$F_{m\alpha} = -\gamma_{m\alpha\beta} \mathcal{W}^\beta. \quad (\text{A9})$$

In other words,

$$\partial_m A_\alpha - D_\alpha A_m + [A_m, A_\alpha] = -\gamma_{m\alpha\beta} \mathcal{W}^\beta. \quad (\text{A10})$$

Next the second identity $I_{m\alpha\beta} = 0$ together with (A9) implies

$$\gamma_{m\alpha\delta} \nabla_\beta \mathcal{W}^\delta + \gamma_{m\beta\delta} \nabla_\alpha \mathcal{W}^\delta - \gamma_{\alpha\beta}^n F_{nm} = 0. \quad (\text{A11})$$

Multiplying this by $\gamma_p^{\alpha\beta}$, we find that

$$F_{mn} = \frac{1}{8} (\gamma_{mn})_\alpha{}^\beta \nabla_\beta \mathcal{W}^\alpha, \quad (\text{A12})$$

which is equivalent to

$$\nabla_\alpha \mathcal{W}^\beta = -\frac{1}{4} (\gamma^{mn})_\alpha{}^\beta F_{mn}. \quad (\text{A13})$$

The third identity $I_{mna} = 0$ implies

$$\nabla_\alpha F_{mn} = \gamma_{n\alpha\beta} \nabla_m \mathcal{W}^\beta - \gamma_{m\alpha\beta} \nabla_n \mathcal{W}^\beta. \quad (\text{A14})$$

Taking (A13) into account, (A14) yields the result

$$\gamma_{\alpha\beta}^m \nabla_m \mathcal{W}^\beta = 0. \quad (\text{A15})$$

Furthermore, multiplying (A15) by $\gamma^{n\gamma\alpha} \nabla_\gamma$ we find

$$\nabla^m F_{mn} = -\frac{1}{2} \gamma_{n\alpha\beta} \{\mathcal{W}^\alpha, \mathcal{W}^\beta\}. \quad (\text{A16})$$

Equations (A16) and (A15) imply the Maxwell equation for the gauge field $\nabla_m f^{mn} = 0$ and the Dirac equation for the gaugino $\gamma_{\alpha\beta}^m \nabla_m \xi^\beta = 0$, respectively.

Finally, the remaining identity $I_{mnp} = 0$ implies

$$\nabla_m F_{np} + \nabla_n F_{pm} + \nabla_p F_{mn} = 0, \quad (\text{A17})$$

and it suggests that F_{mn} is just the curl of a gauge field A_m :

$$F_{mn} = \partial_m A_n - \partial_n A_m + [A_m, A_n]. \quad (\text{A18})$$

The θ -expansion of these superfields is studied in [51].

APPENDIX B: MASSLESS VERTEX OPERATOR FOR PURE SPINOR OPEN SUPERSTRING

We present a review of the vertex operators in the open pure spinor superstring [23] (see also [32]). For simplicity, we focus on the left-moving sector only.

We consider a ghost number 1 massless vertex operator given by

$$U = \lambda^\alpha A_\alpha(x, \theta), \quad (\text{B1})$$

where $A_\alpha(x, \theta)$ is a spinor superfield. The BRS transformation law is represented as

$$\begin{aligned} Qx^m &= \frac{1}{2}\lambda\gamma^m\theta, & Q\theta^\alpha &= \lambda^\alpha, & Qd_\alpha &= -\Pi^m(\gamma_m\lambda)_\alpha, \\ Q\lambda^\alpha &= 0, & Q\omega_\alpha &= d_\alpha, \end{aligned} \quad (\text{B2})$$

where Q denotes δ_1 in Sec. III A. Note that $Q^2\omega_\alpha = -\Pi^m(\gamma_m\lambda)_\alpha$ turns out the gauge transformation for ω_α . Then the cohomology condition, $QU = 0$ up to the gauge transformation $\delta U = Q\Omega$, implies

$$D_\alpha(\gamma_{mnpqr})^{\alpha\beta}A_\beta = 0 \quad \text{and} \quad \delta A_\alpha = D_\alpha\Omega, \quad (\text{B3})$$

where $\Omega(x, \theta)$ is a gauge parameter, the derivative D_α is given in (A2).

To derive (B3), we use the pure spinor constraint for the commutative bispinor λ :

$$\lambda^\alpha\lambda^\beta = \frac{1}{2^5 5!} \gamma_{mnpqr}^{\alpha\beta} (\lambda^\gamma \gamma_{\gamma\delta}^{mnpqr} \lambda^\delta). \quad (\text{B4})$$

As a result, (B3) is consistent with the super-Yang-Mills equations of motion and the gauge transformations as we have seen in Appendix A.

Next, we derive an integrated vertex operator such as $V = \int dz\mathcal{V}$. Recalling the RNS formulation, \mathcal{V} is given as the anticommutator of the unintegrated vertex operator U and the b -ghost. However, in the pure spinor formulation, the reparametrization b -ghost is unclear without introducing the nonminimal part [41].⁶ Fortunately, the above facts can be rephrased in terms of the BRS charge Q as⁷

$$Q\mathcal{V} = \partial U. \quad (\text{B6})$$

We find the vertex operator \mathcal{V} takes the form of

$$\begin{aligned} \mathcal{V} &= \partial\theta^\alpha A_\alpha(x, \theta) + \Pi^m A_m(x, \theta) + d_\alpha \mathcal{W}^\alpha(x, \theta) \\ &+ \frac{1}{2} N^{mn} F_{mn}(x, \theta), \end{aligned} \quad (\text{B7})$$

where $N^{mn} = \frac{1}{2}\lambda\gamma^{mn}\omega$ is the ghost Lorentz current. Indeed, since

⁶The nonminimal pure spinor formalism extended to the Maxwell background is investigated in [52].

⁷The Jacobi identity implies

$$\begin{aligned} Q\mathcal{V} &= [Q, \{\oint dz b, U\}] \\ &= -[U, \{Q, \oint dz b\}] - [\oint dz b, \{U, Q\}] = \partial U \end{aligned} \quad (\text{B5})$$

since $\{Q, U\} = 0$, $\{Q, b\} = T$ and $[\oint dz T, U] = \partial U$ for the conformal weight zero primary operator U .

$$\begin{aligned} Q\mathcal{V} &= \partial(\lambda^\alpha A_\alpha) + \lambda^\alpha \partial\theta^\beta (-D_\alpha A_\beta - D_\beta A_\alpha + \gamma_{\alpha\beta}^m A_m) \\ &+ \lambda^\alpha \Pi^m (D_\alpha A_m - \partial_m A_\alpha - \gamma_{m\alpha\beta} \mathcal{W}^\beta) \\ &+ \lambda^\alpha d_\beta \left(-D_\alpha \mathcal{W}^\beta + \frac{1}{4} (\gamma^{mn})_\alpha^\beta F_{mn} \right) + \frac{1}{2} \lambda^\alpha N^{mn} D_\alpha F_{mn}, \end{aligned} \quad (\text{B8})$$

(B7) implies the following equations:

$$-D_\alpha A_\beta - D_\beta A_\alpha + \gamma_{\alpha\beta}^m A_m = 0, \quad (\text{B9})$$

$$D_\alpha A_m - \partial_m A_\alpha - \gamma_{m\alpha\beta} \mathcal{W}^\beta = 0, \quad (\text{B10})$$

$$-D_\alpha \mathcal{W}^\beta + \frac{1}{4} (\gamma^{mn})_\alpha^\beta F_{mn} = 0, \quad (\text{B11})$$

$$\lambda^\alpha \lambda^\beta (\gamma^{mn})_{\beta\gamma} D_\alpha F_{mn} = 0. \quad (\text{B12})$$

Equations (B9)–(B11) certainly correspond to the super-Yang-Mills equations (A6), (A10) and (A13) in the Abelian case, respectively. It follows that superfields A_α and A_m are spinor and vector gauge fields in the ten-dimensional $\mathcal{N} = 1$ super-Yang-Mills theory, and that \mathcal{W}^α and F_{mn} are spinor and vector field strengths for them. On the other hand, (B12) is satisfied by the pure spinor constraint

$$\begin{aligned} \lambda^\alpha \lambda^\beta (\gamma^{mn})_{\beta\gamma} D_\alpha F_{mn} &= 4\lambda^\alpha \lambda^\beta D_\alpha D_\beta \mathcal{W}^\gamma \\ &= 2(\lambda\gamma^m\lambda)\partial_m \mathcal{W}^\gamma = 0, \end{aligned} \quad (\text{B13})$$

where (B11) is used. If (B9) is contracted with $(\gamma_{mnpqr})^{\alpha\beta}$, we obtain the equation of motion for A_α in (B3). Contraction of (B9) with $\gamma_n^{\alpha\beta}$ also leads to

$$A_m = \frac{1}{8} \gamma_m^{\alpha\beta} D_\alpha A_\beta. \quad (\text{B14})$$

Then the gauge transformation in (B3) turns to $\delta A_m = \partial_m \Omega$. Similarly contracting (B10) with $\gamma^{m\alpha\gamma}$ implies the equation for \mathcal{W}^α ,

$$\mathcal{W}^\beta = \frac{1}{10} \gamma^{m\alpha\beta} (D_\alpha A_m - \partial_m A_\alpha), \quad (\text{B15})$$

and contracting (B11) with $(\gamma^{pq})_\beta^\alpha$ implies the equation for F_{mn} ,

$$F_{mn} = \frac{1}{8} (\gamma_{mn})_\alpha^\beta D_\beta \mathcal{W}^\alpha. \quad (\text{B16})$$

Furthermore, utilizing (B14), (B10) and (B16), we derive

$$\begin{aligned} \partial_{[m} A_{n]} &= -\frac{1}{8} \gamma_{[m}^{\alpha\beta} D_\alpha (\partial_{n]} A_\beta) = -\frac{1}{8} \gamma_{[m}^{\alpha\beta} D_\alpha (D_\beta A_{n]} - (\gamma_{n]} \mathcal{W})_\beta) \\ &= \frac{1}{8} (\gamma_{mn})_\beta^\alpha D_\alpha \mathcal{W}^\beta = F_{mn}. \end{aligned} \quad (\text{B17})$$

Besides, this equation together with (B10) implies

$$D_\alpha F_{mn} = \partial_{[m} D_{|\alpha} A_{n]} = \partial_{[m} (\gamma_n \mathcal{W})_\alpha. \quad (\text{B18})$$

(B17) and (B18) certainly correspond to remaining Bianchi identities (A18) and (A14) for the Abelian case, respectively.

APPENDIX C: BRS CHARGE CONSERVATION

We will derive the supersymmetric DBI equations by modifying the method used in [24] to include the Dirichlet components.

We require that the general variation $\delta(S_0 + S_b + V)$ vanishes. This leads to boundary conditions in the presence of background superfields. Under these conditions, it is shown that the BRS charge conservation implies superfield equations for DBI fields.

Let us begin to examine a general variation of the worldsheet action S_0 in (2.1), its ten-dimensional $\mathcal{N} = 1$ supersymmetry counterterm S_b in (3.4) and the background coupling V in (4.1). We find that variations $\delta(S_0 + S_b)$ and δV may be expressed as

$$\begin{aligned} \delta(S_0 + S_b) = & \frac{1}{2\pi\alpha'} \int d\tau \left\{ \delta\theta_+^\alpha \left[\frac{1}{2} d_\alpha^- + \Pi_+^\mu (\gamma_\mu \theta_-)_\alpha + \tilde{\Pi}_+^i (\gamma_i \theta_-)_\alpha - y_i (\gamma^i \dot{\theta}_+)_\alpha + \frac{1}{6} (\theta_- \gamma^m \dot{\theta}_-) (\gamma_m \theta_-)_\alpha \right] \right. \\ & + \delta\theta_-^\alpha \left[\frac{1}{2} (1 - c_1) \Delta_\alpha^+ - \frac{1}{6} (\theta_- \gamma^m \dot{\theta}_+) (\gamma_m \theta_-)_\alpha \right] - \delta y_+^\mu \left[\tilde{\Pi}_{-\mu} - \frac{1}{2} (\theta_- \gamma_\mu \dot{\theta}_+) \right] \\ & \left. + \delta \tilde{\Pi}_+^i y_i + \frac{1}{2} c_1 \delta \Delta_\alpha^+ \theta_-^\alpha + \frac{1}{2} (c_2 - 1) \omega_\alpha^+ \delta \lambda_-^\alpha + \frac{1}{2} c_2 \delta \omega_\alpha^+ \lambda_-^\alpha - \frac{1}{2} \omega_\alpha^- \delta \lambda_+^\alpha \right\}, \end{aligned} \quad (\text{C1})$$

$$\begin{aligned} \delta V = & \frac{1}{2\pi\alpha'} \int d\tau \left\{ \delta\theta_+^\alpha \left[\dot{\theta}_+^\beta (\gamma_{\alpha\beta}^\mu A_\mu - D_\alpha A_\beta - D_\beta A_\alpha) + \Pi_+^\mu (D_\alpha A_\mu - \partial_\mu A_\alpha) + \tilde{\Pi}_+^i D_\alpha A_i - \frac{1}{2} \Delta_\beta^+ D_\alpha \mathcal{W}^\beta + \frac{1}{4} D_\alpha (N_+ \mathcal{F}) \right] \right. \\ & + \delta y_+^\mu \left[\dot{\theta}_+^\alpha (\partial_\mu A_\alpha - D_\alpha A_\mu) + \Pi_+^\nu (\partial_\mu A_\nu - \partial_\nu A_\mu) + \tilde{\Pi}_+^i \partial_\mu A_i + \frac{1}{2} \Delta_\alpha^+ \partial_\mu \mathcal{W}^\alpha + \frac{1}{4} \partial_\mu (N_+ \mathcal{F}) \right] + \delta \tilde{\Pi}_+^i A_i \\ & \left. + \frac{1}{2} \delta \Delta_\alpha^+ \mathcal{W}^\alpha + \frac{1}{8} \delta \lambda_+^\alpha \mathcal{F}^\beta{}_\alpha \omega_\beta^+ + \frac{1}{8} \lambda_+^\alpha \mathcal{F}^\beta{}_\alpha \delta \omega_\beta^+ \right\}, \end{aligned} \quad (\text{C2})$$

where δy^μ defined by

$$\delta y_+^\mu = \delta x^\mu + \frac{1}{2} (\theta_+ \gamma^\mu \delta \theta_+) \quad (\text{C3})$$

is invariant under the $\mathcal{N} = 1$ supersymmetry. We also see that $\delta(S_0 + S_b)/\delta y_i = 0$ as mentioned in Sec. III.

To obtain boundary conditions from $\delta(S_0 + S_b + V) = 0$, first we focus on the terms with $\delta \Delta_\alpha^+$ and $\delta \omega_\alpha^+$, and derive

$$\theta_-^\alpha = -\frac{1}{c_1} \mathcal{W}^\alpha, \quad \lambda_-^\alpha = -\frac{1}{4c_2} \lambda_+^\beta \mathcal{F}^\alpha{}_\beta. \quad (\text{C4})$$

They also lead to

$$\begin{aligned} \dot{\theta}_-^\alpha &= -\frac{1}{c_1} (\Pi_+^\mu \partial_\mu \mathcal{W}^\alpha + \dot{\theta}_+^\beta D_\beta \mathcal{W}^\alpha), \\ \delta\theta_-^\alpha &= -\frac{1}{c_1} (\delta y_+^\mu \partial_\mu \mathcal{W}^\alpha + \delta\theta_+^\beta D_\beta \mathcal{W}^\alpha), \\ \delta\lambda_-^\alpha &= -\frac{1}{4c_2} \delta\lambda_+^\beta \mathcal{F}^\alpha{}_\beta - \frac{1}{4c_2} (\lambda_+^\beta \delta y_+^\mu \partial_\mu \mathcal{F}^\alpha{}_\beta + \lambda_+^\beta \delta\theta_+^\gamma D_\gamma \mathcal{F}^\alpha{}_\beta). \end{aligned} \quad (\text{C5})$$

Next, examining the terms with $\delta\lambda_+^\alpha$ in $\delta(S_0 + S_b + V)$ we find

$$\omega_\alpha^- = \frac{1}{4c_2} \omega_\beta^+ \mathcal{F}^\beta{}_\alpha. \quad (\text{C6})$$

Boundary conditions for λ_-^α in (C4) and ω_α^- in (C6) are consistent with the ghost number charge conservation $\lambda^\alpha \omega_\alpha = \hat{\lambda}^\alpha \hat{\omega}_\alpha$, where “ $\hat{\cdot}$ ” means “evaluated at the boundary.” On the other hand, we can eliminate the terms with $\delta \tilde{\Pi}_+^i$ in $\delta(S_0 + S_b + V)$ by the identification (4.14). After substituting the above conditions into $\delta(S_0 + S_b + V) = 0$, we examine the terms with δy_+^μ and $\delta\theta_+^\alpha$. They lead to complicated boundary conditions:

$$\begin{aligned}\tilde{\Pi}_{-\mu} &= \dot{\theta}_+^\alpha \left(\partial_\mu A_\alpha - D_\alpha A_\mu + \frac{1}{2c_1} (\gamma_\mu \mathcal{W})_\alpha + \frac{1}{6c_1^3} (\gamma^m \mathcal{W})_\alpha (\mathcal{W} \gamma_m \partial_\mu \mathcal{W}) \right) \\ &\quad + \Pi_+^\nu (\partial_\mu A_\nu - \partial_\nu A_\mu) + \tilde{\Pi}_+^i \partial_\mu A_i + \frac{1}{2c_1} \Delta_\alpha^+ \partial_\mu \mathcal{W}^\alpha + \frac{1}{4c_2} \partial_\mu (N_+ \mathcal{F}),\end{aligned}\quad (\text{C7})$$

$$\begin{aligned}\frac{1}{2} d_\alpha^- &= \dot{\theta}_+^\beta \left(D_\alpha A_\beta + D_\beta A_\alpha - \gamma_{\alpha\beta}^m A_m - \frac{1}{6c_1^3} (\mathcal{W} \gamma^m D_\beta \mathcal{W}) (\gamma_m \mathcal{W})_\alpha - \frac{1}{6c_1^3} (\mathcal{W} \gamma^m D_\alpha \mathcal{W}) (\gamma_m \mathcal{W})_\beta \right) \\ &\quad + \Pi_+^\mu \left(\partial_\mu A_\alpha - D_\alpha A_\mu + \frac{1}{c_1} (\gamma_\mu \mathcal{W})_\alpha + \frac{1}{6c_1^3} (\mathcal{W} \gamma^m \partial_\mu \mathcal{W}) (\gamma_m \mathcal{W})_\alpha \right) \\ &\quad + \tilde{\Pi}_+^i \left(\frac{1}{c_1} (\gamma_i \mathcal{W})_\alpha - D_\alpha A_i \right) + \frac{1}{2c_1} \Delta_\beta^+ D_\alpha \mathcal{W}^\beta - \frac{1}{4c_2} D_\alpha (N_+ \mathcal{F}).\end{aligned}\quad (\text{C8})$$

Equation (C7) is regarded as a modified Neumann boundary condition. Boundary conditions for ω_α^- in (C6) and d_α^- in (C8) must be consistent with the BRS transformation $\delta_Q \omega_\alpha^- = d_\alpha^-$ up to the Λ -gauge transformation in Sec. II. In the following discussion, we will absorb c_1 and c_2 by rescaling $\mathcal{W}^\alpha \rightarrow c_1 \mathcal{W}^\alpha$ and $\mathcal{F}^\beta_\alpha \rightarrow c_2 \mathcal{F}^\beta_\alpha$.

To extract DBI equations, we impose the following relation for BRS currents:

$$\lambda^\alpha d_\alpha = \hat{\lambda}^\alpha \hat{d}_\alpha, \quad (\text{C9})$$

which implies BRS charge conservation

$$0 = \partial_\tau Q_{\text{total}} = \int d\sigma \partial_\tau (j_{\text{BRS}}^\tau) = \int d\sigma \partial_\sigma (j_{\text{BRS}}^\sigma) = \int d\sigma \partial_\sigma (j_{\text{BRS}}^\sigma - \hat{j}_{\text{BRS}}^\sigma) = (\lambda^\alpha d_\alpha - \hat{\lambda}^\alpha \hat{d}_\alpha). \quad (\text{C10})$$

Then we assume the Dirichlet boundary condition

$$\Pi_{-i} = -\Pi_+^\mu \partial_\mu A_i - \dot{\theta}_+^\alpha D_\alpha A_i + \frac{1}{2c_1} (\dot{\theta}_+ \gamma_i \mathcal{W}). \quad (\text{C11})$$

This is parallel with the Neumann boundary condition in (C7) and just the derivation of the identification (4.14) with respect to the time-coordinate τ .

Under these boundary conditions (C4), (C7), (C8) and (C11), the BRS charge conservation (C9) implies

$$\begin{aligned}0 &= \hat{\lambda}^\alpha \hat{d}_\alpha - \lambda^\alpha d_\alpha \\ &= \frac{1}{2} \lambda_+^\alpha d_\alpha^- + \frac{1}{2} \lambda_+^\alpha \Delta_\alpha^+ - \frac{1}{2} (\lambda_- \gamma_\mu \theta_-) \tilde{\Pi}_+^\mu - \frac{1}{2} (\lambda_- \gamma_i \theta_-) \Pi_{-i} - \frac{1}{4} (\lambda_- \gamma^m \theta_-) (\theta_- \gamma_m \dot{\theta}_+) \\ &= \lambda_+^\alpha \dot{\theta}_+^\beta \left[D_\alpha A_\beta + D_\beta A_\alpha - \gamma_{\alpha\beta}^m A_m - \frac{1}{6} (\mathcal{W} \gamma^m D_\beta \mathcal{W}) (\gamma_m \mathcal{W})_\alpha - \frac{1}{6} (\mathcal{W} \gamma^m D_\alpha \mathcal{W}) (\gamma_m \mathcal{W})_\beta \right. \\ &\quad \left. + \frac{1}{8} \mathcal{F}^\gamma_\alpha (\gamma^m \mathcal{W})_\gamma \left\{ \partial_m A_\beta - D_\beta A_m + (\gamma_m \mathcal{W})_\beta + \frac{1}{6} (\gamma^n \mathcal{W})_\beta (\mathcal{W} \gamma_n \partial_m \mathcal{W}) \right\} \right] \\ &\quad + \lambda_+^\alpha \Pi_+^\mu \left[\partial_\mu A_\alpha - D_\alpha A_\mu + (\gamma_\mu \mathcal{W})_\alpha + \frac{1}{6} (\mathcal{W} \gamma^m \partial_\mu \mathcal{W}) (\gamma_m \mathcal{W})_\alpha + \frac{1}{8} \mathcal{F}^\beta_\alpha (\gamma^n \mathcal{W})_\beta (\partial_\mu A_n - \partial_n A_\mu) \right] \\ &\quad + \lambda_+^\alpha \tilde{\Pi}_+^i \left[-D_\alpha A_i + (\gamma_i \mathcal{W})_\alpha - \frac{1}{8} \mathcal{F}^\beta_\alpha (\gamma^\mu \mathcal{W})_\beta \partial_\mu A_i \right] + \frac{1}{2} \lambda_+^\alpha \Delta_\beta^+ \left[D_\alpha \mathcal{W}^\beta - \frac{1}{4} \mathcal{F}^\beta_\alpha + \frac{1}{8} \mathcal{F}^\gamma_\alpha (\gamma^\mu \mathcal{W})_\gamma \partial_\mu \mathcal{W}^\beta \right] \\ &\quad - \frac{1}{4} \lambda_+^\alpha N_{+\gamma}^\beta \left[D_\alpha \mathcal{F}^\gamma_\beta + \frac{1}{8} \mathcal{F}^\delta_\alpha (\gamma^\mu \mathcal{W})_\delta \partial_\mu \mathcal{F}^\gamma_\beta \right].\end{aligned}\quad (\text{C12})$$

Finally, we find that, to eliminate this expression, (4.31), (4.27), (4.19), (4.20) and (4.26) should be required, as expected. The first four equations are supersymmetric DBI equations of motion on a Dp -brane, and the last one is the pure spinor constraint.
