(Received 13 March 2023; accepted 27 September 2023; published 2 November 2023)

We propose a novel realization of the Nelson-Barr mechanism “seeded” by a dark sector containing scalars and vectorlike quarks. Charge parity ( $CP$ ) and a  $\mathcal{Z}_8$  symmetry are spontaneously broken by the complex vacuum expectation value of a singlet scalar, leaving a residual  $\mathcal{Z}_2$  symmetry that stabilizes dark matter (DM). A complex Cabibbo-Kobayashi-Maskawa matrix arises via one-loop corrections to the quark mass matrix mediated by the dark sector. In contrast with other proposals where nonzero contributions to the strong  $CP$  phase arise at the one-loop level, in our case this occurs only at two loops, enhancing naturalness. Our scenario also provides a viable weakly interacting massive particle scalar DM candidate.

### I. INTRODUCTION

There are three experimental facts which call for new physics, beyond the Standard Model (SM): the observation of neutrino oscillations, the existence of some kind of dark matter (DM), and the matter-antimatter asymmetry of the Universe. Besides these proofs of its incompleteness, some unaesthetic aspects of the SM also require a natural explanation. One of these issues is the well-known strong charge-parity ( $CP$ ) problem which can be formulated as a question: Why does quantum chromodynamics (QCD), the theory of strong interactions, seem to preserve  $CP$  when one would expect otherwise?

$CP$  violation (CPV) in QCD is encoded in the so-called strong  $CP$  phase  $\bar{\theta}$  which induces nonvanishing contributions to the neutron electric dipole moment (nEDM). At present, the nEDM is constrained by experiment to be  $\lesssim 3 \times 10^{-26} e \text{ cm}$  [1,2], implying

$$|\bar{\theta}| \lesssim 10^{-10}. \quad (1)$$

This seems to indicate that QCD does not violate  $CP$  at all. On the other hand,  $CP$  is maximally broken in weak interactions. From this point of view, tiny (or vanishing) CPV in the strong sector appears unnatural. A popular

solution to the strong  $CP$  problem assumes a global anomalous Peccei-Quinn (PQ) symmetry which, after spontaneous breaking, gives rise to a pseudo-Goldstone boson—the axion [3–5]. The bottom line of the PQ mechanism is that axion dynamics leads to a  $CP$ -conserving ground state, setting  $\bar{\theta} = 0$ .

Another way of explaining the smallness of  $\bar{\theta}$  is by simply imposing exact  $CP$  symmetry at the Lagrangian level, ensuring a vanishing  $\bar{\theta}$ . However, to account for large CPV effects observed in the quark (weak) sector,  $CP$  must be broken spontaneously in such a way that low-energy CPV is large. This general setup [6–9] can be implemented in SM extensions with extra scalars and/or colored particles which are crucial to break  $CP$  and generate a complex Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix. The drawback of such Nelson-Barr (NB) type models is that, once  $CP$  is broken and the  $CP$  phase in the CKM matrix is large, quantum corrections to  $\bar{\theta}$  must remain under control.

The simplest way of accounting for spontaneous  $CP$  violation (SCPV) is by adding to the SM fields a complex scalar singlet  $\sigma$  which acquires a vacuum expectation value (VEV). To transmit CPV to the SM quark sector, one may introduce a vectorlike quark (VLQ) which couples to  $\sigma$  in some way. Once  $CP$  is broken by the  $\sigma$  VEV, CPV appears generating a complex CKM matrix. This is the essence of the model proposed by Bento, Branco, and Parada (BBP) in Ref. [10]. We note, however, that such minimal NB realization produces dangerous contributions to the strong  $CP$  phase already at the one-loop level, thus requiring some rather strong assumptions to keep  $\bar{\theta}$  under control [Eq. (1)].

Here, we propose a new NB-type scenario, in which the strong  $CP$  phase arises only at two loops, while CPV in the CKM matrix arises via one-loop corrections mediated by a dark sector. After SCPV induced by the complex VEV of a

scalar singlet  $\sigma$ , the dark particles remain odd under a  $\mathcal{Z}_2$  symmetry, the lightest of them (a scalar) providing a viable weakly interacting massive particle (WIMP) DM candidate. A key feature of our dark-mediated solution to the strong  $CP$  problem is that threshold corrections to  $\bar{\theta}$  arise only at two loops, alleviating the NB “quality problem.”

## II. MODEL AT TREE LEVEL

A crucial ingredient in our construction is SCPV, which is simply realized by the VEV of a complex scalar singlet  $\sigma$ . This is possible if the scalar potential of the theory includes phase-sensitive terms as, e.g.,  $\sigma^4$  and  $\sigma^2$ , invariant under a  $\mathcal{Z}_N$  discrete symmetry if  $\sigma \rightarrow \omega^k \sigma$  with  $\omega = e^{2i\pi/N}$  and  $k = pN/4$  ( $p \in \mathbb{Z}$ ). Our minimal choice is  $N = 8$ . Thus, besides gauge invariance under the SM group  $G_{\text{SM}} = \text{SU}(3)_c \otimes \text{SU}(2)_L \otimes \text{U}(1)_Y$  and under  $CP$ , our theory also has a  $\mathcal{Z}_8$  symmetry.

To implement our dark-matter-mediated NB solution to the strong  $CP$  problem, we add three down-type VLQs, namely, one VLQ  $B_{L,R}$  and two odd (dark)  $D_{iL,iR}$  ( $i = 1, 2$ ). Besides  $\sigma$  and the SM Higgs doublet  $\Phi$ , we also have two inert complex scalar singlets  $\chi$  and  $\xi$ , which are also dark. The transformation properties of all fields under  $G_{\text{SM}}$  and the  $\mathcal{Z}_8$  symmetry are shown in Table I. We denote the SM left-handed quark doublets and right-handed up and down quark singlets by  $q_L = (u_L d_L)^T$  and  $u_R/d_R$ , respectively, with Yukawa interactions

$$-\mathcal{L}_{\text{Yuk}} \supset \mathbf{Y}_u \bar{q}_L \tilde{\Phi} u_R + \mathbf{Y}_d \bar{q}_L \Phi d_R + \mathbf{Y}_\xi \bar{D}_{2L} d_R \xi + \mathbf{Y}_\chi \bar{D}_{1L} d_R \chi^* + \text{H.c.}, \quad (2)$$

where  $\Phi = (\phi^+ \phi^0)^T$  and  $\tilde{\Phi} = i\tau_2 \Phi^*$ ,  $\tau_2$  being the complex Pauli matrix. Here,  $\mathbf{Y}_{u,d}$  ( $\mathbf{Y}_{\chi,\xi}$ ) are  $3 \times 3$  ( $1 \times 3$ ) matrices, and, as usual,  $\langle \phi^0 \rangle = v/\sqrt{2} \simeq 174$  GeV. The Yukawa couplings involving only new fields read

$$-\mathcal{L}_{\text{Yuk}} \supset y_\chi \bar{B}_L D_{2R} \chi + y_\xi \bar{B}_L D_{1R} \xi^* + y'_\chi \bar{D}_{2L} B_R \chi^* + y'_\xi \bar{D}_{1L} B_R \xi + \text{H.c.}, \quad (3)$$

where  $y_{\chi,\xi}^{(\prime)}$  are numbers, and bare VLQ mass terms are

$$-\mathcal{L}_{\text{mass}} = m_B \bar{B}_L B_R + m_{D_{1,2}} \bar{D}_{1,2L} D_{1,2R} + \text{H.c.} \quad (4)$$

Notice that Eqs. (2)–(4) contain all gauge-invariant Yukawa and mass terms which respect the  $\mathcal{Z}_8$  symmetry.  $CP$  invariance of the Lagrangian implies that all coupling and mass parameters are real.

The  $\mathcal{Z}_8$  symmetry is broken down to a  $\mathcal{Z}_2$  (see Table I) by the  $\sigma$  VEV  $\langle \sigma \rangle = v_\sigma e^{i\varphi}/\sqrt{2}$ . In the limit of exact  $\mathcal{Z}_8$  invariance, the only phase-sensitive term in the scalar potential is  $\lambda_\sigma (\sigma^4 + \sigma^{*4})$ . Minimization leads to  $\varphi = \pi/4 + k\pi/2$  ( $k \in \mathbb{Z}$ ). Note that this solution does not violate  $CP$ , since a generalized  $CP$  transformation can be defined such that the vacuum remains invariant. Furthermore, spontaneous breaking of an exact discrete symmetry could lead to cosmological domain-wall problems.<sup>1</sup> We, thus, consider a scenario in which the  $\mathcal{Z}_8$  is softly broken by the bilinear term  $m_\sigma^2 (\sigma^2 + \sigma^{*2})$ , fixing the domain-wall problem. This leads to a  $CP$ -violating phase  $\varphi$  that can, in principle, be arbitrary.

It is straightforward to see that, since there are no  $\mathcal{Z}_8$ -invariant quark- $\sigma$  couplings, the  $4 \times 4$  tree-level down-quark mass matrix  $\mathcal{M}_d^{(0)}$  in the  $(dB)_{L,R}$  basis is block-diagonal and real, with the SM quarks decoupled from the VLQ  $B$ . Hence, CPV will not be communicated to the quark sector and the CKM matrix is real.<sup>2</sup> Since

$$\bar{\theta} = \arg[\det(\mathbf{M}_u)] + \arg[\det(\mathcal{M}_d)], \quad (5)$$

where  $\mathbf{M}_u = \mathbf{Y}_u v/2$  is the SM up-quark mass matrix, we obviously have  $\bar{\theta} = 0$ .

## III. COMPLEX CKM AT ONE LOOP WITH $\bar{\theta} = 0$

Beyond tree level, the down-quark mass matrix can be written in the generic form  $\mathcal{M}_d = \mathcal{M}_d^{(0)} + \Delta \mathcal{M}_d$  with

$$\mathcal{M}_d^{(0)} = \begin{pmatrix} \mathbf{M}_d & 0 \\ 0 & m_B \end{pmatrix}, \quad \Delta \mathcal{M}_d = \begin{pmatrix} \Delta \mathbf{M}_d & \Delta \mathbf{M}_{dB} \\ \Delta \mathbf{M}_{Bd} & \Delta m_B \end{pmatrix}, \quad (6)$$

where  $\mathbf{M}_d = \mathbf{Y}_d v/\sqrt{2}$  and  $m_B$  is the bare  $B$  mass term; see Eqs. (2) and (4). Higher-order corrections to  $\mathcal{M}_d^{(0)}$  are

<sup>1</sup>This might not be an issue if our mechanism is embedded in a more general framework providing a solution to that problem (see, e.g., [11]).

<sup>2</sup>In contrast, in Ref. [10] the allowed couplings  $\bar{B}_L d_R \sigma^{(*)}$  would yield a complex  $\bar{B}_L d_R$  mass term and a complex tree-level CKM.

FIG. 1. “Dark-mediated” diagrams for the dim-5 operators  $\overline{B}_L d_R \sigma^{(*)2}$  leading to  $\Delta \mathbf{M}_{Bd}$  after  $\mathcal{Z}_8$  symmetry breaking.

encoded in  $\Delta \mathcal{M}_d$ , and a necessary condition to generate a complex effective CKM matrix is that at least one of the correcting terms is complex. The most intuitive way of investigating how this may happen is to look for higher-order operators which can generate complex mass terms after SCPV. Such operators must be gauge and  $\mathcal{Z}_8$  invariant and contain unmatched powers of  $\sigma^{(*)}$ , given that the  $\sigma$  VEV phase  $\varphi$  is the only source of CPV in our framework. Then one must check at which loop order those operators arise and compute the corresponding corrections  $\Delta \mathcal{M}_d$ .

At dimension five, phase-sensitive operators which induce corrections to  $\mathcal{M}_d$  are  $\overline{B}_L d_R \sigma^{(*)2}$ ; these specifically contribute, after SCPV, to  $\Delta \mathbf{M}_{Bd}$ . In contrast, the operators  $\overline{B}_L B_R (\Phi^\dagger \Phi)$  and  $\overline{B}_L B_R |\sigma|^2$  lead to real  $\Delta m_B$ . Notice that, since  $\sigma$  does not couple to quarks, we require interactions with the dark sector to induce those operators at the quantum level.

The lowest-order phase-sensitive operators induced at one loop are  $\overline{B}_L d_R \sigma^{(*)2}$ , which generate  $\Delta \mathbf{M}_{Bd}$  after symmetry breaking. The corresponding Feynman diagrams in the weak basis are shown in Fig. 1. The trilinear and quartic scalar terms involving  $\sigma$  and the dark fields  $\zeta = \chi, \xi$  are all  $\mathcal{Z}_8$  symmetric. The contributions in Fig. 1 are roughly estimated as

$$|\Delta \mathbf{M}_{Bd}| \sim \frac{1}{16\pi^2} \lambda_{\sigma\zeta\zeta} |\mathbf{Y}_\zeta| y_\zeta \frac{v_\sigma^2}{m_\zeta^2} m_D, \quad (7)$$

$$|\Delta \mathbf{M}_{Bd}| \sim \frac{1}{16\pi^2} |\mathbf{Y}_\zeta| y_\zeta \frac{\mu_\zeta^2}{m_\zeta^2} \frac{v_\sigma^2}{m_\zeta^2} m_D, \quad (8)$$

for the left and right diagram, respectively. Here,  $\mathbf{Y}_\zeta$  and  $y_\zeta$  represent generic  $\mathbf{Y}_{\chi,\xi}$  and  $y_{\chi,\xi}$  couplings of Eq. (3), respectively, while  $\lambda_{\sigma\zeta\zeta}$  and  $\mu_\zeta$  are quartic and trilinear terms of the scalar potential, respectively. It is clear that  $\Delta \mathbf{M}_{Bd}$  is complex due to the interference of different terms which pick up the phases  $\pm 2\varphi$  from the VEVs of  $\sigma^2$  and  $\sigma^{*2}$ . Similar one-loop diagrams exist for  $\overline{B}_L B_R (\Phi^\dagger \Phi)$  and  $\overline{B}_L B_R |\sigma|^2$ ; these, however, lead to a real  $\Delta m_B$ .

The one-loop down-quark mass matrix is then

$$\mathcal{M}_d^{(1)} = \begin{pmatrix} \mathbf{M}_d & 0 \\ \Delta \mathbf{M}_{Bd} & \hat{m}_B \end{pmatrix}, \quad \hat{m}_B = m_B + \Delta m_B. \quad (9)$$

In the limit  $\mathbf{M}_d \ll \hat{m}_B$ , the (complex) CKM matrix can be obtained diagonalizing  $\mathbf{M}_{\text{light}}^2$  given by

$$\mathbf{M}_{\text{light}}^2 \simeq \mathbf{M}_d \mathbf{M}_d^T - \frac{\mathbf{M}_d \Delta \mathbf{M}_{Bd}^\dagger \Delta \mathbf{M}_{Bd} \mathbf{M}_d^T}{\tilde{m}_B^2}, \quad (10)$$

with  $\tilde{m}_B^2 \simeq |\Delta \mathbf{M}_{Bd}|^2 + \hat{m}_B^2$ . Whether CPV is successfully transmitted to the SM sector depends on the relative size between  $\Delta \mathbf{M}_{Bd}$  and  $\hat{m}_B$ . In fact, in this case, generating a viable CKM requires  $|\Delta \mathbf{M}_{Bd}| \gtrsim \hat{m}_B$ .

Notice that  $\bar{\theta} = \arg[\det(\mathbf{M}_u)] + \arg[\det(\mathcal{M}_d)] = 0$ , since  $\mathbf{M}_d$  and  $\hat{m}_B$  are real, and  $\Delta \mathbf{M}_{dB} = 0$ . This is the key feature of our dark-seeded NB mechanism, which is in contrast with the BBP model where corrections to  $\bar{\theta}$  appear already at the one-loop level. In our case,  $\bar{\theta}$  remains zero at this order of perturbation theory.

#### IV. CORRECTIONS BEYOND ONE LOOP

At the two-loop level, complex corrections to  $\mathbf{M}_d$  and  $m_B$  induce contributions to  $\bar{\theta}$  which can be estimated as

$$\Delta \bar{\theta}|_{\Delta \mathbf{M}_d} \sim \frac{1}{(16\pi^2)^2} \lambda_{\Phi\sigma} y_d^2 \frac{v_\sigma^2}{v^2}, \quad (11)$$

$$\Delta \bar{\theta}|_{\Delta m_B} \sim \frac{1}{(16\pi^2)^2} \lambda_{\sigma\zeta} y_\zeta y'_\zeta \frac{m_D}{m_B} \frac{v_\sigma^2}{m_\zeta^2}, \quad (12)$$

where  $m_\zeta$  is a typical dark scalar mass and  $y_\zeta^{(i)}$  are generic  $y_{\xi,\chi}^{(i)}$  couplings. Here,  $\lambda_{\Phi\sigma}$  is the  $(\Phi^\dagger \Phi)|\sigma|^2$  quartic scalar coupling, and  $\lambda_{\sigma\zeta}$  stands for generic  $\lambda_{\sigma\chi}|\sigma|^2|\chi|^2$  and  $\lambda_{\sigma\xi}|\sigma|^2|\xi|^2$  couplings. For typical values for the SM quark Yukawa couplings  $y_d \sim \mathcal{O}(10^{-2})$ , the first correction above is under control if  $\lambda_{\Phi\sigma} \lesssim v^2/v_\sigma^2$ . This is reasonable, as the physics accounting for the Higgs hierarchy is likely to also provide a small  $\lambda_{\Phi\sigma}$ . On the other hand, if all mass scales in Eq. (12) are of the same order,  $\Delta \bar{\theta}|_{\Delta m_B} \lesssim 10^{-10}$  requires  $|\lambda_{\sigma\zeta} y_\zeta y'_\zeta| \lesssim 10^{-6}$ , which can be easily accommodated. In fact, in our framework, the U(1)-sensitive couplings with the dark sector can be naturally small in the 't Hooft sense [12], since the Lagrangian symmetry is enlarged in their absence. Note that, the above contributions come from operators  $\overline{q}_L \Phi d_R \sigma^{(*)4}$  and  $\overline{B}_L B_R \sigma^{(*)4}$ .

Concerning higher-loop corrections, we have checked that the contributions to  $\bar{\theta}$  arise from three (four) loops via  $\Delta \mathbf{M}_{d,dB} (m_B)$ , which can be estimated as

$$\Delta \bar{\theta}|_{\Delta \mathbf{M}_{dB}} \sim \frac{\Delta \bar{\theta}|_{\Delta \mathbf{M}_d}}{16\pi^2} \sim \frac{1}{(16\pi^2)^2} \lambda_{\Phi\sigma} \frac{|\Delta \mathbf{M}_{Bd}|^2}{v_\sigma^2}, \quad (13)$$

$$\Delta \bar{\theta}|_{\Delta m_B} \sim \frac{g^2}{(16\pi^2)^2} \frac{|\Delta \mathbf{M}_{Bd}|^2}{v_\sigma^2}, \quad (14)$$

where  $g \sim \mathcal{O}(1)$  is a weak coupling and we have considered a  $\mathcal{O}(1)$  coupling for the  $|\sigma|^4$  term. It is straightforward to see that  $|\Delta\mathbf{M}_{Bd}| \lesssim 10^{-3}v_\sigma$  is required to keep these corrections under control (as long as  $\lambda_{\Phi\sigma}$  is made small in a framework where the Higgs mass is stabilized). One may now ask how natural is it to verify this condition in our scenario. In the above estimates,  $\Delta\mathbf{M}_{Bd}$  is the one-loop correction in Eq. (9); see Fig. 1 and Eqs. (7) and (8). From those estimates, one sees that, to ensure  $|\Delta\mathbf{M}_{Bd}| \lesssim 10^{-3}v_\sigma$ , one roughly needs  $|\mathbf{Y}_\zeta|y_\zeta \lesssim m_\zeta^2/(m_D v_\sigma)$  for  $\lambda_{\sigma\zeta\zeta} \lesssim 1$  and  $\mu_\zeta \sim m_\zeta$ . This condition is attainable for reasonable values of dark sector couplings and wide mass ranges. In contrast, models where  $\mathbf{M}_{Bd}$  is generated at tree level via a  $y_B\sigma^{(*)}\overline{B}_L d_R$  have been argued to suffer from a quality problem, requiring a small  $y_B \lesssim 10^{-3}$  [13,14].

Indeed, in the original BBP scenario,  $\Delta\mathbf{M}_{dB}$  and  $\Delta m_B$  receive contributions from dim-5 operators of the type  $\overline{q}_L\Phi B_R\sigma^{(*)}$  and  $\overline{B}_L B_R\sigma^{(*)2}$ , respectively. These affect  $\bar{\theta}$  in a way that  $\Delta\bar{\theta} \lesssim 10^{-10}$  sets an upper bound on the SCPV scale  $v_\sigma \lesssim 10^3\text{--}10^8$  GeV, for a cutoff  $\Lambda$  at the Planck scale [15,16]. This hierarchy between  $v_\sigma$  and  $\Lambda$  is the essence of the NB quality problem. As recently noted in Ref. [17], such a low SCPV scale may have a drastic impact in cosmology. In our case, the lowest dimension operators that would induce corrections to  $\bar{\theta}$  are the dim-6  $y_\Lambda\overline{q}_L\Phi B_R\sigma^{(*)2}$ , for which we estimate

$$\Delta\bar{\theta}|_{\Delta\mathbf{M}_{dB}} \sim \frac{|\Delta\mathbf{M}_{Bd}|y_\Lambda}{m_B y_d} \left(\frac{v_\sigma}{\Lambda}\right)^2. \quad (15)$$

Taking  $|\Delta\mathbf{M}_{Bd}|/m_B \gtrsim \mathcal{O}(1)$  to generate a viable complex CKM matrix and  $y_\Lambda \sim \mathcal{O}(1)$  with  $y_d \sim 10^{-5} - 1$ , we get that  $\Delta\bar{\theta}|_{\Delta\mathbf{M}_{dB}} \lesssim 10^{-10}$  requires only  $v_\sigma \lesssim 10^8\text{--}10^{13}$  GeV, a milder hierarchy between those scales.

## V. PHENOMENOLOGY

We have seen that  $|\Delta\mathbf{M}_{Bd}| \lesssim 10^{-3}v_\sigma$  and  $|\Delta\mathbf{M}_{Bd}| \gtrsim \hat{m}_B$  are needed to simultaneously satisfy the  $\bar{\theta}$  bound of Eq. (1) and successfully transmit CPV to the CKM matrix. These constraints, together with the 1.4 TeV LHC limit on the  $B$  VLQ mass [18], imply  $v_\sigma \gtrsim 10^3$  TeV. Figure 2 shows a scatter plot of  $m_D/m_{\zeta_1}$  versus  $|y|\mathbf{Y}|$ , with quark masses and CKM parameters within their  $1\sigma$  experimental ranges [19], and the  $B$  VLQ mass above the LHC limit. All results have been obtained using exact one-loop computation of  $\Delta\mathbf{M}_{Bd}$  and diagonalizing the full  $\mathcal{M}_d^{(1)}$ . Notice that we obtain viable points over a wide range of dark couplings and masses.

Concerning DM, we assume a benchmark dark scalar mass spectrum of the type  $m_{\zeta_1} \ll m_{\zeta_{2,3,4}}$ ,  $\zeta_1$  being our DM candidate. As seen in Fig. 3, our scenario differs from the simplest scalar-singlet DM case [20–25] due to the presence of even scalars  $H_{1,2}$  arising from  $\sigma$ . Besides the viable

FIG. 2.  $m_D/m_{\zeta_1}$  versus  $|y|\mathbf{Y}|$ , where  $m_D = (m_{D_1} + m_{D_2})/2$  and  $|y|\mathbf{Y}| = (y_\chi|\mathbf{Y}_\zeta| + y_\zeta|\mathbf{Y}_\chi|)/2$ —see Eqs. (2)–(4). We set  $v_\sigma = 10^3$  TeV. Above the dashed contours,  $m_{\zeta_1}$  lies below the labeled value. The same holds to the right of the dash-dotted vertical lines for the heaviest dark-scalar mass  $m_{\zeta_4}$ .

FIG. 3. Higgs-DM coupling  $g_{h11}$  versus WIMP DM mass  $m_{\zeta_1}$ . Along the blue contour, the DM relic density lies in the Planck  $3\sigma$  range [29]. The blue shaded region below that leads to overabundant DM. The green shaded region is excluded by the LZ experiment [30]. The violet and orange contours indicate the projected sensitivities for LZ [26], XENONnT [27], and DARWIN [28], respectively. The pink dashed line is the “neutrino floor” limit [31]. The brown-shaded region is excluded by the LHC bound on the Higgs invisible decay [19].

relic density dip at  $m_{\zeta_1} \sim m_h/2 \simeq 62.6$  GeV (SM Higgs boson),  $H_{1,2}$  open up new annihilation channels which reproduce the observed DM relic abundance. As shown in the figure, our dark sector can be probed by future direct detection experiments, e.g., LZ [26], XENONnT [27], and DARWIN [28].

## VI. CONCLUDING REMARKS

In this paper, we propose a new solution to the strong  $CP$  problem based on the existence of a dark sector containing

a viable (scalar) WIMP DM candidate, as seen in Fig. 3. In our NB-inspired mechanism, a  $\mathcal{Z}_8$  symmetry allows for SCPV while leaving a residual  $\mathcal{Z}_2$  to stabilize DM. A complex CKM matrix arises from one-loop corrections to the quark mass matrix mediated by the dark sector; see Figs. 1 and 2. In contrast with other proposals, here the strong  $CP$  phase receives nonzero contributions only at two loops, enhancing naturalness.

Our setup can be embedded in a more general framework aiming at addressing other drawbacks of the SM, besides the strong  $CP$  problem and DM. For instance, the VEV of the complex scalar singlet  $\sigma$  could be responsible for generating neutrino masses, inducing simultaneously low-energy  $CP$  violation in the lepton mixing matrix [32]. Moreover, the same scalar may also play a key role in creating the lepton asymmetry required for leptogenesis

[33] as well as driving inflation [34]. This opens a window for interesting studies where a dark sector provides a unique solution to several open questions in (astro)particle physics and cosmology.
