In this work, we investigate the isospin breaking decay $X_b \rightarrow \pi^0\chi_{bJ}$ and the isospin conserved decay $X_b \rightarrow \pi\pi\chi_{bJ}$, where X_b is taken to be the heavy quark flavor symmetry counterpart of $X(3872)$ in the bottomonium sector as a $B^*\bar{B}$ molecule candidate. Since the mass of this state may be far below the $B\bar{B}^*$ threshold and the mass difference between the neutral and charged bottom meson is small compared to the binding energy of the X_b , the isospin-violating decay channel $X_b \rightarrow \pi^0\chi_{bJ}$ would be highly suppressed. The calculated partial width of $X_b \rightarrow \pi\pi\chi_{b1}$ is found to be about tens of keVs, 1–2 order(s) of magnitude larger than those of $X_b \rightarrow \pi\pi\chi_{b2}$ and $X_b \rightarrow \pi\pi\chi_{b0}$. Taking into account the fact that the total width of X_b may be smaller than a few MeV like $X(3872)$, the calculated branching ratios $X_b \rightarrow \pi\pi\chi_{b1}$ may reach to orders of 10^{-2} , which makes it a possible channel for the experimental searching of the X_b .

DOI: 10.1103/PhysRevD.109.034017

I. INTRODUCTION

In the past decades, a large number of so-called XYZ states has been discovered on the experiments, and tremendous effort has been taken to unravel their nature beyond the conventional quark model [1–7]. In 2003, a narrow structure $X(3872)$ ($\chi_{c1}(3872)$) was reported in the $J/\psi\pi^+\pi^-$ invariant mass distribution in $B^+ \rightarrow K^+J/\psi\pi^+\pi^-$ process by the Belle Collaboration [8]. Subsequently, it was gradually confirmed in the e^+e^- collisions by BABAR Collaboration [9], and in the $pp/p\bar{p}$ collisions by D0 [10], CDF [11], and LHCb Collaborations [12,13]. Its quantum numbers were pinned down to $J^{PC} = 1^{++}$ [14]. The $X(3872)$ may be the most renowned exotic candidates with two salient features. One is its very narrow decay width compared to the typical hadronic width, $\Gamma[X(3872)] < 1.2$ MeV; the other is its mass is close to the $D\bar{D}^*$ threshold [15], $M_{X(3872)} - M_{D^0} - M_{D^{*0}} = (-0.12 \pm 0.24)$ MeV. Based on these two features, it is naturally suggest that the $X(3872)$ might be a $D\bar{D}^*$ hadronic molecule [16,17].

The observation of the $X(3872)$ [8] shows that the meson spectroscopy is far more complicated than the naive expectation of the quark model. It is natural to search for the posited bottomonium counterpart of the $X(3872)$ with $J^{PC} = 1^{++}$ (called X_b hereafter) [18,19]. As the heavy quark flavor symmetry (HQFS) partner of the $X(3872)$, X_b should share some universal properties with the $X(3872)$. The search for X_b can provide us with important information on the discrimination between the compact multiquark configuration and the loosely bound hadronic molecule configuration for the $X(3872)$ [20]. The existence of the X_b is predicted both in the molecular interpretation [21–24] and the tetraquark model [25], with a mass coincide with the $B\bar{B}^*$ threshold [2,21–23,26–32], or in the 10 to 11 GeV/ c^2 range [18,25,33,34], respectively. Such a heavy mass of X_b makes it less likely to be discovered in current electron-positron collision facilities, although the Super KEKB may provide an opportunity for searching it in the radiative decays of the $\Upsilon(5S, 6S)$ [35]. The production of the X_b at hadron colliders such as LHCb and Tevatron [31,36] have been extensively investigated [37–42] and shows sizeable production rate. Therefore, a suitable decay mode from which the X_b state can be reconstructed is imperatively called for. Unlike the $X(3872)$, the isospin breaking decay of the X_b to $\pi^+\pi^-\Upsilon(1S)$ should be highly suppressed since the X_b may be far below the $B\bar{B}^*$ threshold and the mass difference between neutral and charged bottom mesons is very small, which may explain the null result reported by the CMS, ATLAS Collaborations [43,44] for searching the X_b in the $\pi^+\pi^-\Upsilon(1S)$ final state.

The isospin conserved hidden bottomonium decay $X_b \rightarrow \omega\Upsilon(1S)$ has been investigated in Ref. [45] with the intermediate meson-loop (IML) contributions, but no significant signal is observed in the experiments [20,46]. The partial widths of the radioactive decays $X_b \rightarrow \gamma\Upsilon(nS)$ was calculated in Ref. [29] and their magnitude is about 1 keV. In this work, we will focus on the isospin conserved decay of $X_b \rightarrow \pi\pi\chi_{bJ}$ ($J = 0, 1, 2$), which could have sizeable branching fractions and be possible channels for the X_b reconstruction.

The $X_b \rightarrow \pi\pi\chi_{bJ}$ decays are studied in the bottom IML mechanism. The impact of the IML on the heavy quarkonium transitions has been investigated in the Υ decay processes $\Upsilon(4S) \rightarrow h_b(1P, 2P)\pi^+\pi^-$, $\Upsilon(4S) \rightarrow \Upsilon(1S, 2S)\pi^+\pi^-$, and $\Upsilon(2S, 3S, 4S) \rightarrow \Upsilon(1S, 2S)\pi\pi$ [47–49], and gave results consistent with the experimental data. In this work, the partial decay widths of $X_b \rightarrow \pi^0\pi^0\chi_{bJ}(1P)$ and $X_b \rightarrow \pi^+\pi^+\chi_{bJ}(1P)$ ($J = 0, 1, 2$) are calculated by using the heavy hadron chiral perturbation theory (HH χ PT), including the contribution from the box IML.

The rest of this paper is organized as follows. In Sec. II, we introduce the effective Lagrangians and Feynman diagrams for the hadronic decays of the X_b to $\pi^0\chi_{bJ}$ and $\pi\pi\chi_{bJ}$. Our numerical results are presented in Sec. III, and a brief summary is given in Sec. IV.

II. EFFECTIVE LAGRANGIANS AND POWER COUNTING

In this section, we will give the effective Lagrangians and Feynman diagrams for the hadronic decays of X_b to $\pi^0\chi_{bJ}$ and $\pi\pi\chi_{bJ}$. The X_b is assumed to be an S -wave molecular state with $J^{PC} = 1^{++}$ given by the superposition of $B^0\bar{B}^{*0} + \text{c.c.}$ and $B^-B^{*+} + \text{c.c.}$ hadronic configurations as [45]

$$|X_b\rangle = \frac{1}{\sqrt{2}} \cos\varphi (|B^0\bar{B}^{*0}\rangle + |B^{*0}\bar{B}^0\rangle) + \frac{1}{\sqrt{2}} \sin\varphi (|B^+B^{*-}\rangle + |B^-B^{*+}\rangle), \quad (1)$$

where the charge conjugation conventions $B^* \xrightarrow{C} \bar{B}^*$ and $B \xrightarrow{C} \bar{B}$ is used, and φ is a phase angle describing the proportion of neutral and charged constituents, which will be settled in Sec. III by the cancellation of the neutral and charged meson loops in the isospin-violating processes $X_b \rightarrow \pi^0\chi_{bJ}$. The effective Lagrangian for the X_b coupling to the $B^*\bar{B}$ can be written as

$$\begin{aligned} \mathcal{L}_{X_{BB^*}} &= \frac{g_n}{\sqrt{2}} X^{i\dagger} (B^{*0i}\bar{B}^0 + B^0\bar{B}^{*0i}) + \frac{g_c}{\sqrt{2}} X^{i\dagger} \\ &\times (B^{*+i}B^- + B^+B^{*-i}) + \text{H.c.}, \end{aligned} \quad (2)$$

where g_n and g_c denote the coupling constant of the X_b to the neutral and charged bottom meson pairs, respectively. As an isoscalar $B^*\bar{B}$ molecular state, the X_b state appears as a pole

on the real axis in the complex energy plane of the $B^{*+}B^- - B^{*0}\bar{B}^0$ coupled channel T matrix with $C = +$, and the effective couplings g_n and g_c can be derived from the residues of the T matrix elements at the X_b pole and read [50,51]

$$g_n = \frac{4\sqrt{\pi\gamma_n}}{\mu_n} \cos\varphi, \quad (3)$$

$$g_c = \frac{4\sqrt{\pi\gamma_c}}{\mu_c} \sin\varphi, \quad (4)$$

where $\gamma_n = \sqrt{2\mu_n E_{X_b}^n}$ and $\gamma_c = \sqrt{2\mu_c E_{X_b}^c}$ with $E_{X_b}^n = m_{B^{*0}} + m_{B^0} - m_{X_b}$, $E_{X_b}^c = m_{B^{*+}} + m_{B^+} - m_{X_b}$ the binding energies of the X_b relative to the $B^0\bar{B}^{*0}$ and B^+B^{*-} thresholds, respectively, and $\mu_n = m_{B^{*0}}m_{B^0}/(m_{B^{*0}} + m_{B^0})$, $\mu_c = m_{B^{*+}}m_{B^+}/(m_{B^{*+}} + m_{B^+})$ are the reduced masses.

The leading-order heavy hadron chiral perturbation theory (HH χ PT) Lagrangian for mesons containing heavy quarks or antiquarks at rest is [52]

$$\begin{aligned} \mathcal{L}_{B^{(*)}B^*\phi} &= -g\text{Tr}[H_a^\dagger H_b \vec{\sigma} \cdot \vec{A}_{ba}] + g\text{Tr}[\bar{H}_a^\dagger \vec{\sigma} \cdot \vec{A}_{ab} \bar{H}_b] \\ &+ \text{Tr}[H_a^\dagger (iD_0)_{ba} H_b] + \text{Tr}[\bar{H}_a^\dagger (iD_0)_{ba} \bar{H}_b], \end{aligned} \quad (5)$$

where $\vec{\sigma}$ denote the Pauli matrices and a is the light flavor index, the bottom mesons are given by the two-component notation [53] as $H_a = \vec{V}_a \cdot \vec{\sigma} + P_a$ with $P = (B^-, \bar{B}^0)$ and $V = (B^{*-}, \bar{B}^{*0})$ denote the pseudoscalar and vector heavy mesons, respectively, and the field for the antimesons is $\bar{H}_a = -\vec{V}_a \cdot \vec{\sigma} + \bar{P}_a$ with $\bar{P} = (B^+, B^0)$ and $\bar{V} = (B^{*+}, B^{*0})$. The first two terms in Eq. (5) give the interaction between the heavy mesons and pions. The field $\vec{A}_{ab} = -\vec{\nabla} \Phi_{ab}/f_\pi + \dots$ is the axial current in the chiral perturbation theory (χ PT) and couples to the heavy mesons with the axial coupling $g = 0.54$ [50], where $f_\pi = 130$ MeV is the pion decay constant, and the Φ field contains the Goldstone bosons as components,

$$\Phi = \begin{pmatrix} \frac{1}{\sqrt{2}}\pi^0 & \pi^+ \\ \pi^- & -\frac{1}{\sqrt{2}}\pi^0 \end{pmatrix}. \quad (6)$$

The last two terms in Eq. (5) describe the $B^{(*)}B^{(*)}\pi\pi$ interaction, where $D_0 = \partial_0 - V_0$, $V_\mu = \frac{1}{2}(u^\dagger \partial_\mu u + u \partial_\mu u^\dagger)$ is the vector current in the χ PT with $u = \exp(i\Phi/f_\pi)$.

The Lagrangian couples the χ_{bJ} to heavy mesons reads

$$\begin{aligned} \mathcal{L}_{\chi B^{(*)}B^{(*)}} &= i\frac{g_1}{2} \text{Tr}[\chi^{i\dagger} H_a \sigma^i \bar{H}_a] + \frac{c_1}{2} \text{Tr}[\chi^{i\dagger} H_a \sigma^j \bar{H}_b] \epsilon_{ijk} A_{ab}^k \\ &+ \text{H.c.}, \end{aligned} \quad (7)$$

where the χ_{bJ} field is expressed as [52]

FIG. 1. Feynman diagrams for calculating the partial decay width of $X_b \rightarrow \pi^0 \chi_{bJ}$ and $\pi\pi \chi_{bJ}$.

$$\chi^i = \sigma^j \chi^{ij} = \sigma^j \left(\chi_{b2}^{ij} + \frac{1}{\sqrt{2}} \epsilon^{ijk} \chi_{b1}^k + \frac{\delta^{ij}}{\sqrt{3}} \chi_{b0} \right), \quad (8)$$

with the coupling constant $g_1 = 0.53_{-0.13}^{+0.19}$ GeV $^{-1/2}$ [47].

The Feynman diagrams of $X_b \rightarrow \pi^0 \chi_{bJ}$ and $X_b \rightarrow \pi\pi \chi_{bJ}$ are shown in Fig. 1 with all the possible combination of the intermediate particles in the loops of each diagram listed in Table I. In Table I, the first particle in each square bracket denotes the top (in the two-point bubble), or top left (in the triangle and box) intermediate bottom meson in the corresponding diagram, and the other intermediate bottom mesons in the same diagram are listed in the square bracket in counterclockwise order along the loop.

Since the X_b is close to the $B\bar{B}^*$ threshold, the velocity of the intermediate heavy meson $v_{B^{(*)}} = \sqrt{|E_{X_b}|/m_{B^{(*)}}}$ should be smaller than 1 (in units of the speed of light) and become a natural small quantity for the power counting of the diagrams in Fig. 1. The diagrams can be counted in the powers of v and

p_π , where $p_\pi \simeq (m_{X_b} - m_{\chi_{bJ}})/2$ is the momentum of the external pion, and $v = (v_{X_b} + v_{\chi_{bJ}})/2$ with $v_{X_b} \simeq 0.03$ and $v_{\chi_{bJ}} \simeq 0.40$ derived from taking the X_b binding energy to be $E_{X_b}^n = 5$ MeV. In each diagram, the nonrelativistic energy counts as v^2 , each loop integral is at v^5 , and each non-relativistic propagator contributes at v^{-2} . For the vertices, the $B^{(*)}B^{(*)}\pi\pi$ vertex is proportional to the square of the energy of the pion $E_\pi^2 \sim p_\pi^2$, the P -wave $B^*\bar{B}\pi\chi_{bJ}$ and $B^{(*)}B^{(*)}\pi$ vertices are proportional to p_π , while the $X_b B^{(*)}\bar{B}^{(*)}$ and $B^{(*)}\bar{B}^{(*)}\chi_{bJ}$ vertices are in S -wave and count at $v^0 p_\pi^0$. The diagrams of $X_b \rightarrow \pi^0 \chi_{bJ}$ shown in Figs. 1(a) and 1(b) scales as $v^5 p_\pi / (v^2)^2 = p_\pi v$ and $v^5 p_\pi / (v^2)^3 = p_\pi / v$, respectively. For the decay $X_b \rightarrow \pi\pi \chi_{bJ}$, the box diagrams Figs. 1(c) and 1(d) scales as $v^5 p_\pi^2 / (v^2)^4 = p_\pi^2 / v^3$, and the triangle diagrams in Figs. 1(e) and 1(f) scale as $v^5 p_\pi^2 / (v^2)^3 = p_\pi^2 / v$ and $v^5 p_\pi^2 / (v^2)^3 = p_\pi^2 / v$, respectively. One can see the contributions from the two-point bubble diagrams to the

TABLE I. All the possible combinations of the intermediate heavy mesons for the diagrams in Fig. 1. The first particle in each square bracket denotes the top (in the two-point bubble), or top left (in the triangle and box) intermediate bottom meson in the corresponding diagram, and the other intermediate bottom mesons in the same diagram are listed in the square bracket in counterclockwise order along the loop.

Figures 1(e) and 1(f)	$[B^*, \bar{B}, B^*], [B^*, \bar{B}, B], [\bar{B}^*, B, \bar{B}^*], [\bar{B}^*, B, \bar{B}], [B, \bar{B}^*, B^*], [B, \bar{B}^*, B], [\bar{B}, B^*, \bar{B}^*], [\bar{B}, B^*, \bar{B}]$

$X_b \rightarrow \pi\chi_{bJ}$ decays are suppressed by v^2 relative to the triangle diagrams, and the contributions from the triangle diagrams to the $X_b \rightarrow \pi\pi\chi_{bJ}$ decays are suppressed by v^2 comparing with the box diagrams. Thus, for a rough estimate of the partial decay width, we only consider the contribution of the triangle diagrams to the decay widths of $X_b \rightarrow \pi\chi_{bJ}$ and the box diagrams to the decay widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ in this work, and a evaluation of the omitted contributions from the bubble diagrams to the decay widths of $X_b \rightarrow \pi\chi_{bJ}$ and the triangle diagrams to the decay widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ is given in Appendix B.

Based on the Lagrangians given above, the loop transition amplitudes in Fig. 1 can be expressed in a general form as follows:

$$\mathcal{A}[X_b \rightarrow \pi\chi_{bJ}] = V_1 V_2 V_3 \times I[m_1, m_2, m_3], \quad (9)$$

$$\mathcal{A}[X_b \rightarrow \pi\pi\chi_{bJ}] = V_1 V_2 V_3 V_4 \times I[m_1, m_2, m_3, m_4], \quad (10)$$

where V_n ($n = 1, 2, 3, 4$) represent the vertex functions for the initial X_b , final χ_{bJ} and π , respectively. The expressions of the 3-point and 4-point integral functions $I[m_1, m_2, m_3]$, and $I[m_1, m_2, m_3, m_4]$ are given in the Appendix A, where m_i ($i = 1, 2, 3, 4$) represents the mass of i th particle of each combination of the intermediate states listed in Table I and all the combinations in each diagram should be summed to get the final amplitude. Note that these amplitudes must be multiplied by a factor of $\sqrt{m_{X_b} m_{\chi_{bJ}} m_1 m_2 m_3}$, or $\sqrt{m_{X_b} m_{\chi_{bJ}} m_1 m_2 m_3 m_4}$ to account for the nonrelativistic normalization of the HH χ PT. With all the amplitudes, the decay rate for the X_b decay is given by

$$d\Gamma = \frac{1}{2SM} \frac{1}{2j+1} \sum_{\text{spins}} |\mathcal{A}|^2 d\Phi_n, \quad (11)$$

where the symmetry factor S is taken to be 2 in the $X_b \rightarrow \pi^0\pi^0\chi_{bJ}$ decays considering the identical $\pi^0\pi^0$ particles in the final states, and to be 1 in the decays $X_b \rightarrow \pi^0\chi_{bJ}$ and

$X_b \rightarrow \pi^+\pi^-\chi_{bJ}$, j is the total spin of the initial particle, and there is a sum over all the polarizations of the final-state particles. The $d\Phi_n$ ($n = 2, 3$) is the two-body phase space or three-body phase space, which can be obtained from Refs. [54,55].

III. NUMERICAL RESULTS

In this section, we give the partial decay widths of the $X_b \rightarrow \pi^0\chi_{bJ}$, $\pi^0\pi^0\chi_{bJ}$, and $\pi^+\pi^-\chi_{bJ}$. As the binding energy of the X_b is uncertain, covering the mass range of the X_b predicted by the molecular and tetraquark model in Refs. [21–23,25] could be a good approximation for calculating the decay widths and might be applicable. In Ref. [25], the mass of the lowest-lying $1^{++} \bar{b}\bar{q}bq$ tetraquark was predicted to be 10504 MeV. In the molecular interpretation, it was predicted to be 10562 MeV, which is approximately 42 MeV below the $B\bar{B}^*$ threshold [21], and (10580^{+9}_-8) MeV with a binding energy of (24^{+8}_-9) MeV [23]. Thus, we performed the calculations up to a binding energy of 100 MeV, and choose several illustrative values of $E_{X_b}^n = (2, 5, 10, 25, 50, 100)$ MeV ($E_{X_b}^c = E_{X_b}^n - 1.2$ MeV) for discussion.

It is likely that the X_b is below the $B^*\bar{B}$ threshold and the mass difference between the neutral and charged bottom meson is small compared to the binding energy of the X_b [21–23,25], the isospin violating decay mode $X_b \rightarrow \pi^0\chi_{bJ}$ would be greatly suppressed. Based on this point, we can determine the charged and neutral bottom meson components of X_b to some extent. If we assume that the proportions of the neutral and charged components are the same. i.e., $\varphi = \pi/4$ in Eq. (1), the calculated partial decay widths are

$$\Gamma[\pi^0\chi_{b0}] = 13.10 \text{ keV}, \quad (12)$$

$$\Gamma[\pi^0\chi_{b1}] = 8.64 \text{ keV}, \quad (13)$$

$$\Gamma[\pi^0\chi_{b2}] = 12.83 \text{ keV}, \quad (14)$$

FIG. 2. $\Gamma[\pi^0\chi_{b0}]/\Gamma[\pi^0\chi_{b2}]$ and $\Gamma[\pi^0\chi_{b1}]/\Gamma[\pi^0\chi_{b2}]$ as a function of φ .

TABLE II. Predicted partial widths (in units of keV) of the X_b decays. The units of the binding energy $E_{X_b}^n$ in first column are MeV.

	$\Gamma^B[\pi^0\pi^0\chi_{b0}]$	$\Gamma^B[\pi^0\pi^0\chi_{b1}]$	$\Gamma^B[\pi^0\pi^0\chi_{b2}]$	$\Gamma^B[\pi^+\pi^-\chi_{b0}]$	$\Gamma^B[\pi^+\pi^-\chi_{b1}]$	$\Gamma^B[\pi^+\pi^-\chi_{b2}]$
$E_{X_b}^n = 2$ MeV	0.13	10.00	2.07	0.24	18.36	3.89
$E_{X_b}^n = 5$ MeV	0.18	14.60	3.11	0.33	27.61	5.85
$E_{X_b}^n = 10$ MeV	0.19	16.98	3.62	0.35	32.09	6.80
$E_{X_b}^n = 25$ MeV	0.15	16.52	3.50	0.27	32.16	6.57
$E_{X_b}^n = 50$ MeV	0.09	12.54	2.54	0.15	23.51	4.74
$E_{X_b}^n = 100$ MeV	0.02	5.62	1.10	0.04	10.41	2.03

which are too large for the isospin breaking processes as the neutral and charged meson loops are not canceled properly. The cancellation can be arranged by finely tuning the angle φ to adjust the charged and neutral mesons components of X_b [50]. The ratios $\Gamma[\pi^0\chi_{b0}]/\Gamma[\pi^0\chi_{b2}]$ and $\Gamma[\pi^0\chi_{b1}]/\Gamma[\pi^0\chi_{b2}]$ with $\varphi \in [0.7, 1.0]$ are shown in Fig. 2. One has $\Gamma[\pi^0\chi_{b0}]/\Gamma[\pi^0\chi_{b2}] \simeq 1.0$ and $\Gamma[\pi^0\chi_{b1}]/\Gamma[\pi^0\chi_{b2}] \simeq 0.7$ for most values of φ except for $\varphi \in [0.81, 0.82]$ where the charged and the neutral loops cancel with each other.

After the careful arrangement of the charged and neutral components in X_b , we give the partial widths of the $X_b \rightarrow \pi\pi\chi_{bJ}$ process with $\varphi = 0.813 \pm 0.005$, which are isospin conserved and not sensitive to the angle φ in the neighborhood of $\varphi = 0.813$. The partial widths of the $X_b \rightarrow \pi\pi\chi_{bJ}$ with $E_{X_b}^n = (2, 5, 10, 25, 50, 100)$ MeV are listed in Table II, where the partial decay widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ ($J = 1, 2$) are about tens of keVs, while the partial decay widths of $X_b \rightarrow \pi\pi\chi_{b0}$ is two orders of magnitude smaller because it is in higher partial waves as analyzed in the follows. The quantum numbers of the identical particle ($\pi^0\pi^0$) system are $I^G(J^{PC}) = 0^+(L^{++})(L = \text{even})$. Considering the conservation of the angular momentum and the P -parity, in the $X_b \rightarrow \pi^0\pi^0\chi_{b0}$ and $X_b \rightarrow \pi^0\pi^0\chi_{b2}$ processes, the two pions in the identical particle system should be at least in D -wave, and this system should also be at least in D -wave and S -wave with the χ_{b0} and χ_{b2} , respectively. While in the $X_b \rightarrow \pi^0\pi^0\chi_{b1}$ decay, both the

two pions and the two-pion system with the χ_{b1} can be in S -wave, therefore the partial widths of $X_b \rightarrow \pi^0\pi^0\chi_{b0}$ are suppressed by the higher partial waves comparing with those of X_b decaying into $\pi^0\pi^0\chi_{b1}$ and $\pi^0\pi^0\chi_{b2}$. For the decays $X_b \rightarrow \pi^+\pi^-\chi_{bJ}$, the quantum numbers of the $(\pi^+\pi^-)$ system satisfy $L + I = \text{even}$ with I the total isospin of the $(\pi^+\pi^-)$ system. For $I = 0$, the discussions are same as the decays to $\pi^0\pi^0\chi_{bJ}$. For $I = 1$, the two charged pions can be in P -wave and the two-pion system and the χ_{b0} can also be in P -wave, and the partial width of the $X_b \rightarrow \pi^+\pi^-\chi_{b0}$ process is still suppressed as it is isospin violated. And one can see that $\Gamma[\pi^+\pi^-\chi_{bJ}]/\Gamma[\pi^0\pi^0\chi_{bJ}] \simeq 2$, same as the $X(3872)$ case [52].

To see the relation between the partial widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ ($J = 0, 1, 2$) and the binding energy of the X_b more precisely, the partial widths versus the binding energy $E_{X_b}^n \in [2, 100]$ MeV are demonstrated in Fig. 3, where the partial widths first increase and then decrease with the $E_{X_b}^n$ increases. This is because the binding energy dependence of the partial width can be influenced by the coupling strength of X_b in Eqs. (3) and (4), and the threshold effects. As the binding energy $E_{X_b}^n$ increases, the coupling strength of X_b increases, while the threshold effects decreases. In the small $E_{X_b}^n$ region, the contribution from the coupling strength of X_b is dominant, while that from the threshold effects plays an important role in the large $E_{X_b}^n$ region.

FIG. 3. The partial decay widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ as a function of the binding energy $E_{X_b}^n$.

One can see that unlike the $X_b \rightarrow \pi^+\pi^-\Upsilon$ which is suppressed by the isospin symmetry, the partial decay widths of the isospin conserved process $X_b \rightarrow \pi\pi\chi_{b1}$ is at the same order of magnitude with the partial width of $X_b \rightarrow \Upsilon(1S)\omega$ calculated in Ref. [45], and it could be better channel for the X_b searching as the ω needs to be reconstructed through the $\pi\pi\pi$ or $\pi^0\gamma$ final states. Therefore, our results can be helpful for hunting the X_b in the experiments.

IV. SUMMARY

In this work, we investigated the isospin breaking decay $X_b \rightarrow \pi^0\chi_{bJ}$ and the isospin conserved decay $X_b \rightarrow \pi\pi\chi_{bJ}$, where X_b is taken to be the HQFS counterpart of $X(3872)$ in the bottomonium sector as a meson-meson molecule candidate. Since the mass of this state may be far below the $B\bar{B}^*$ threshold, the isospin-violating decay channel $X_b \rightarrow \pi^0\chi_{bJ}$ would be highly suppressed and stimulate the importance of the isospin-conserved decay channel $X_b \rightarrow \pi\pi\chi_{bJ}$. The isospin-violating decay channel $X_b \rightarrow \pi^0\chi_{bJ}$ can helps us determine the charged and neutral components of X_b to some extent. For the isospin conserved processes, the calculated partial widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ ($J = 0, 1, 2$) are about less than 1 keV, tens of keVs, and a few keVs, respectively. The partial width of $X_b \rightarrow \pi\pi\chi_{b1}$ is found to be about tens of keVs, 1–2 order(s) of magnitude larger than those of $X_b \rightarrow \pi\pi\chi_{b2}$ and $X_b \rightarrow \pi\pi\chi_{b0}$. Taking into account the fact that the total width of X_b may be smaller than a few MeV like $X(3872)$,

the calculated branching ratios $X_b \rightarrow \pi\pi\chi_{b1}$ may reach to orders of 10^{-2} , which makes it a possible channel for the experimental searching of the X_b . These studies may help us investigate the X_b deeply. The experimental observation of X_b will provide us further insight into the spectroscopy of exotic states and is helpful to probe the structure of the states connected by the heavy quark symmetry.

APPENDIX A: 2-POINT, 3-POINT, AND 4-POINT LOOP INTEGRALS

In this section, we derive the 2-point, 3-point, and 4-point loop integral in the rest frame of the decay particle ($p = (M, 0)$). The 2-point loop integral can be written as [56]

$$\begin{aligned}
I[m_1, m_2] &= i \int \frac{d^4l}{(2\pi)^4} \frac{1}{[l^2 - m_1^2 + i\epsilon][(p-l)^2 - m_2^2 + i\epsilon]} \\
&= \frac{i}{4m_1m_2} \int \frac{d^4l}{(2\pi)^4} \frac{1}{\left[l^0 - m_1 - \frac{l^2}{2m_1} + i\epsilon\right] \left[M - l^0 - m_2 - \frac{l^2}{2m_2} + i\epsilon\right]} \\
&= \frac{1}{4m_1m_2} \int \frac{d^3l}{(2\pi)^3} \frac{1}{b_{12} + \frac{l^2}{2\mu_{12}} - i\epsilon} \\
&= \frac{2\mu_{12}}{4m_1m_2} \int \frac{d^3l}{(2\pi)^3} \frac{1}{l^2 + c_1 - i\epsilon} \\
&= \frac{\mu_{12}}{4\pi^2 m_1 m_2} \left[\Lambda - \sqrt{c_1 - i\epsilon} \tan^{-1} \left(\frac{\Lambda}{\sqrt{c_1 - i\epsilon}} \right) \right], \tag{A1}
\end{aligned}$$

where $\mu_{ij} = m_i m_j / (m_i + m_j)$ are the reduced masses, $b_{12} = m_1 + m_2 - M$, and $c_1 = 2\mu_{12}b_{12}$. The cutoff Λ is taken to be 1 GeV.

FIG. 4. Kinematics used for calculating 4-point integrals.

The scalar 3-point loop integral is ultraviolet (UV) convergent and can be worked out as [56]

$$\begin{aligned}
I[m_1, m_2, m_3] &= i \int \frac{d^4 l}{(2\pi)^4} \frac{1}{[\vec{l}^2 - m_1^2 + i\epsilon][(p-l)^2 - m_2^2 + i\epsilon][(l-q)^2 - m_3^2 + i\epsilon]} \\
&= \frac{i}{8m_1 m_2 m_3} \int \frac{d^4 l}{(2\pi)^4} \frac{1}{\left[l^0 - m_1 - \frac{\vec{l}^2}{2m_1} + i\epsilon\right] \left[M - l^0 - m_2 - \frac{\vec{l}^2}{2m_2} + i\epsilon\right] \left[l^0 - q^0 - m_3 - \frac{(\vec{l}-\vec{q})^2}{2m_3} + i\epsilon\right]} \\
&= \frac{1}{8m_1 m_2 m_3} \int \frac{d^3 l}{(2\pi)^3} \frac{1}{\left(b_{12} + \frac{\vec{l}^2}{2\mu_{12}} - i\epsilon\right) \left[b_{23} + \frac{\vec{l}^2}{2m_2} + \frac{(\vec{l}-\vec{q})^2}{2m_3} - i\epsilon\right]} \\
&= \frac{4\mu_{12}\mu_{23}}{8m_1 m_2 m_3} \int \frac{d^3 l}{(2\pi)^3} \frac{1}{(\vec{l}^2 + c_1 - i\epsilon) \left(\vec{l}^2 - \frac{2\mu_{23}}{m_3} \vec{l} \cdot \vec{q} + c_2 - i\epsilon\right)} \\
&= \frac{4\mu_{12}\mu_{23}}{8m_1 m_2 m_3} \int_0^1 dx \int \frac{d^3 l}{(2\pi)^3} \frac{1}{[\vec{l}^2 - ax^2 + (c_2 - c_1)x + c_1 - i\epsilon]^2} \\
&= \frac{1}{8m_1 m_2 m_3} \frac{4\mu_{12}\mu_{23}}{(4\pi)^{3/2}} \Gamma\left(\frac{1}{2}\right) \int_0^1 dx [-ax^2 + (c_2 - c_1)x + c_1 - i\epsilon]^{1/2} \\
&= \frac{\mu_{12}\mu_{23}}{16\pi m_1 m_2 m_3} \frac{1}{\sqrt{a}} \left[\tan^{-1}\left(\frac{c_2 - c_1}{2\sqrt{ac_1}}\right) + \tan^{-1}\left(\frac{2a + c_1 - c_2}{2\sqrt{a(c_2 - a)}}\right) \right], \tag{A2}
\end{aligned}$$

where $\mu_{ij} = m_i m_j / (m_i + m_j)$ are the reduced masses, $b_{12} = m_1 + m_2 - M$, $b_{23} = m_2 + m_3 + q^0 - M$, and

$$a = \left(\frac{\mu_{23}}{m_3}\right)^2 \vec{q}^2, \quad c_1 = 2\mu_{12}b_{12}, \quad c_2 = 2\mu_{23}b_{23} + \frac{\mu_{23}}{m_3} \vec{q}^2. \tag{A3}$$

The four-point integrals in the box diagrams are given in Ref. [47]. For Fig. 4(a), the initial particle at rest [$p = (M, 0)$] reads

$$\begin{aligned}
I_1[m_1, m_2, m_3, m_4] &\equiv i \int \frac{d^4 l}{(2\pi)^4} \frac{1}{[l^2 - m_1^2 + i\epsilon][(p-l)^2 - m_2^2 + i\epsilon][(l-q_1-q_2)^2 - m_3^2 + i\epsilon][(l-q_1)^2 - m_4^2 + i\epsilon]} \\
&\simeq \frac{-i}{16m_1 m_2 m_3 m_4} \\
&\quad \times \int \frac{d^4 l}{(2\pi)^4} \frac{1}{\left[l^0 - \frac{l^2}{2m_1} - m_1 + i\epsilon\right] \left[l^0 - M + \frac{l^2}{m_2} + m_2 - i\epsilon\right] \left[l^0 - q_1^0 - q_2^0 - \frac{(\vec{l} + \vec{q}_3)^2}{2m_3} - m_3 + i\epsilon\right]} \\
&\quad \times \frac{1}{\left[l^0 - q_1^0 - \frac{(\vec{l} - \vec{q}_1)^2}{2m_4} - m_4 + i\epsilon\right]} \\
&= \frac{-\mu_{12}\mu_{23}\mu_{24}}{2m_1 m_2 m_3 m_4} \int \frac{d^3 l}{(2\pi)^3} \frac{1}{[\vec{l}^2 + c_{12} - i\epsilon] [\vec{l}^2 + 2\frac{\mu_{23}}{m_3} \vec{l} \cdot \vec{q}_3 + c_{23} - i\epsilon] [\vec{l}^2 - 2\frac{\mu_{24}}{m_4} \vec{l} \cdot \vec{q}_1 + c_{24} - i\epsilon]}, \tag{A4}
\end{aligned}$$

where

$$\begin{aligned}
c_{12} &\equiv 2\mu_{12}(m_1 + m_2 - M), & c_{23} &\equiv 2\mu_{23} \left(m_2 + m_3 - M + q_1^0 + q_2^0 + \frac{\vec{q}_3^2}{2m_3} \right), \\
c_{24} &\equiv 2\mu_{24} \left(m_2 + m_4 - M + q_1^0 + \frac{\vec{q}_1^2}{2m_4} \right), & \mu_{ij} &= \frac{m_i m_j}{m_i + m_j}. \tag{A5}
\end{aligned}$$

The m_1 denotes the mass of the top-left intermediate-bottom mesons, and the mass of the other intermediate bottom mesons are labeled as m_2 , m_3 , and m_4 , in counterclockwise order.

As the crossed diagram of the Fig. 4(b) with $p_1 \leftrightarrow p_2$, the scalar integral of the Fig. 4(b) reads

$$I'_1[m_1, m_2, m_3, m_4] = \frac{-\mu_{12}\mu_{23}\mu_{24}}{2m_1 m_2 m_3 m_4} \int \frac{d^3 l}{(2\pi)^3} \frac{1}{[\vec{l}^2 + c_{12} - i\epsilon] [\vec{l}^2 + 2\frac{\mu_{23}}{m_3} \vec{l} \cdot \vec{q}_3 + c_{23} - i\epsilon] [\vec{l}^2 - 2\frac{\mu_{24}}{m_4} \vec{l} \cdot \vec{q}_2 + c'_{24} - i\epsilon]}, \tag{A6}$$

where

$$c'_{24} \equiv 2\mu_{24} \left(m_2 + m_4 - M + q_2^0 + \frac{\vec{q}_2^2}{2m_4} \right). \tag{A7}$$

For the Fig. 4(c),

$$\begin{aligned}
I_2[m_1, m_2, m_3, m_4] &\equiv i \int \frac{d^4 l}{(2\pi)^4} \frac{1}{[l^2 - m_1^2 + i\epsilon][(p-l)^2 - m_2^2 + i\epsilon][(p-l-q_2)^2 - m_3^2 + i\epsilon][(l-q_1)^2 - m_4^2 + i\epsilon]} \\
&\simeq \frac{-i}{16m_1 m_2 m_3 m_4} \\
&\quad \times \int \frac{d^4 l}{(2\pi)^4} \frac{1}{\left[l^0 - \frac{l^2}{2m_1} - m_1 + i\epsilon\right] \left[l^0 - M + \frac{l^2}{m_2} + m_2 - i\epsilon\right] \left[l^0 + q_2^0 - M - \frac{(\vec{l} + \vec{q}_2)^2}{2m_3} + m_3 - i\epsilon\right]} \\
&\quad \times \frac{1}{\left[l^0 - q_1^0 - \frac{(\vec{l} - \vec{q}_1)^2}{2m_4} - m_4 + i\epsilon\right]} \\
&= \frac{-\mu_{12}\mu_{34}}{2m_1 m_2 m_3 m_4} \int \frac{d^3 l}{(2\pi)^3} \frac{1}{[\vec{l}^2 + c_{12} - i\epsilon] \left[\vec{l}^2 - \frac{2\mu_{34}}{m_4} \vec{l} \cdot \vec{q}_1 + \frac{2\mu_{34}}{m_3} \vec{l} \cdot \vec{q}_2 + c_{34} - i\epsilon\right]} \\
&\quad \times \left[\frac{\mu_{24}}{[\vec{l}^2 - \frac{2\mu_{24}}{m_4} \vec{l} \cdot \vec{q}_1 + c_{24} - i\epsilon]} + \frac{\mu_{13}}{[\vec{l}^2 + \frac{2\mu_{13}}{m_3} \vec{l} \cdot \vec{q}_2 + c_{13} - i\epsilon]} \right], \tag{A8}
\end{aligned}$$

where

$$c_{34} \equiv 2\mu_{34} \left(m_3 + m_4 - q_3^0 + \frac{\vec{q}_1^2}{2m_4} + \frac{\vec{q}_2^2}{2m_3} \right), \quad c_{13} \equiv 2\mu_{13} \left(m_1 + m_3 - M + q_2^0 + \frac{\vec{q}_2^2}{2m_3} \right). \quad (\text{A9})$$

APPENDIX B: EVALUATION OF THE TRIANGLE DIAGRAM CONTRIBUTION TO $X_b \rightarrow \pi\pi\chi_{bJ}$ AND THE BUBBLE DIAGRAM CONTRIBUTION TO $X_b \rightarrow \pi\chi_{bJ}$

In this section, we give a rough estimate of the contributions of the omitted triangle diagrams in Figs. 1(e) and 1(f) and the omitted two point bubble diagrams in Fig. 1(a) to the decay widths of $X_b \rightarrow \pi\pi\chi_{bJ}$ and $X_b \rightarrow \pi\chi_{bJ}$, respectively.

Unfortunately, the bubble diagram in Fig. 1(a) and the triangle diagram in Fig. 1(e) contain an unknown coupling c_1 . Hence, we can only give a quantitative estimate of their contributions based on the power counting and naturalness. In our power counting scheme, the ratio of the contributions from the box diagrams to those from the triangle diagrams is

$$1 : v^2. \quad (\text{B1})$$

More specifically, considering the effective couplings c_1 and g_1 , the ratio reads

$$1 : \frac{m_{B^{(*)}} c_1}{g_1} v^2, \quad (\text{B2})$$

where the $m_{B^{(*)}}$ comes from the difference between the triangle and box IML to match the dimensions of c_1 and g_1 . To be consistent with this power counting, it is natural to take $c_1 \simeq g_1/m_{B^*}$ to estimate the contributions from the triangle diagrams, and the results are shown in Table III. The $X_b \rightarrow \pi\pi\chi_{b1}$ decay also contains the contributions of the

triangle diagrams in Fig. 1(f), which is free of the unknown c_1 . The contributions of Figs. 1(e) and 1(f) to the decay widths are at the same orders of magnitude in our power counting, which demands $c_1 \simeq g_1/(\sqrt{10}m_{B^*})$. The decay widths with such a coupling are shown in Table IV. From these evaluations, the contributions of the triangle diagrams to the decay widths are estimated to be 1–3 magnitude smaller than the box diagram contributions.

For the contributions of the bubble diagrams to the $X_b \rightarrow \pi\chi_{bJ}$ decay width, in our power counting scheme, the contributions from bubble diagrams are suppressed by v^2 compared with the triangle diagrams and therefore the bubble diagrams are not considered in the $X_b \rightarrow \pi\chi_{bJ}$ decay in our calculations in Sec. III.

The 2-point integral $I[m_1, m_2]$ given in Appendix A is regularization dependent, and the cut-off dependence of the two body decay widths from the bubble diagram contribution is shown in Fig. 5 with $\Lambda = 0.5\text{--}1.5$ GeV, $\varphi = 0.813$, and $E_{X_b}^n = 5$ MeV. The coupling constant c_1 is also taken to be g_1/m_{B^*} and $g_1/(\sqrt{10}m_{B^*})$ to roughly estimate the contributions from the bubble diagrams, and the results are about 3–4 orders of magnitude smaller than the contributions of the triangle diagrams. The cutoff dependence of the decay widths is not significant for Λ below 1 GeV.

TABLE III. Predicted partial widths (in units of keV) of the X_b decays with $c_1 = g_1/m_{B^*}$.

	$\Gamma^\Gamma[\pi^0\pi^0\chi_{b0}]$	$\Gamma^\Gamma[\pi^0\pi^0\chi_{b1}]$	$\Gamma^\Gamma[\pi^0\pi^0\chi_{b2}]$	$\Gamma^\Gamma[\pi^+\pi^-\chi_{b0}]$	$\Gamma^\Gamma[\pi^+\pi^-\chi_{b1}]$	$\Gamma^\Gamma[\pi^+\pi^-\chi_{b2}]$
