Abstract

This biennial review summarizes much of Particle Physics. Using data from previous editions, plus 1900 new measurements from 700 papers, we list, evaluate, and average measured properties of gauge bosons, leptons, quarks, mesons, and baryons. We also summarize searches for hypothetical particles such as Higgs bosons, heavy neutrinos, and supersymmetric particles. All the particle properties and search limits are listed in Summary Tables. We also give numerous tables, figures, formulae, and reviews of topics such as the Standard Model, particle detectors, probability, and statistics. A booklet is available containing the Summary Tables and abbreviated versions of some of the other sections of this full *Review*.

Special thanks are due to our administrative assistant at LBNL, Gail Harper, for her careful proofreading of the text, layout, and graphics in this *Review*.

^{*}The publication of the Review of Particle Physics is supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, the Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098; by the U.S. National Science Foundation under Agreement No. PHY-9320551; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development; and by the Italian National Institute of Nuclear Physics (INFN).

[‡]Jonathan Feng acknowleges support from the Miller Institute for Basic Research in Science.

[†]In memoriam: Gary S. Wagman, 1954–1995

Gary Wagman, Programmer for the Particle Data Group from 1985 to 1995, died of AIDS on Friday, April 21, 1995. Gary, a respected member of the gay community, was a native of Houston, Texas, and graduated from the University of Houston in Computer Science.

Gary made many contributions to the Particle Data Group, and thus to the entire international high-energy physics community. He did much of the intricate design and all of the advanced programming that brought the *Review of Particle Physics* from its primitive state in 1984 to the beautiful and valuable document it is today, in both its printed and electronic forms. He was recognized a few months before his death with a Lawrence Berkeley Laboratory Outstanding Performance Award for these achievements. Gary's work was characterized by his constant striving for perfection, by his deep concern for accuracy, and by his understanding of our scientific mission.

In addition to his work as a programmer, Gary loved to travel. He was intrigued by exotic and magical places, visiting the pyramids in Egypt and the Taj Mahal in India. Europe was another favorite destination where he enjoyed speaking French. Gary traveled to Israel several times, once spending six months on a kibbutz picking grapefruit. An avid hiker and camper, he also explored many parts the United States.

Gary's meticulous nature led him to excel at woodworking, and he spent several years remodeling his house in San Francisco. A member of the Dahlia Society, he further enhanced his home and garden through his love of flowers. He was also a connoisseur of fine food, eating, and baking, delighting the PDG with many wonderful birthday cakes.

Always interested in spirituality and mysticism, Gary had recently begun studying Sufism. This spiritual practice was so meaningful to him that, in December 1995, he insisted on participating in a Sufi turning exhibition even though he was very ill.

In October 1995, a memorial service was held for Gary at the Pinnacles National Monument in California, one of his favorite spiritual places.

Gary was our friend and colleague for ten years, and all of us who had the privilege of knowing him miss him greatly.

INTRODUCTION

1. Overview

The Review of Particle Physics and the abbreviated version, the Particle Physics Booklet, are reviews of the field of Particle Physics. This complete Review includes a compilation/evaluation of data on particle properties, called the "Particle Listings." These Listings include 1900 new measurements from 700 papers, in addition to the 14,000 measurements from 4000 papers that first appeared in previous editions.

Both books include Summary Tables with our best values and limits for particle properties such as masses, widths or lifetimes, and branching fractions, as well as an extensive summary of searches for hypothetical particles. In addition, we give a long section of "Reviews, Tables, and Plots" on a wide variety of theoretical and experimental topics, a quick reference for the practicing particle physicist.

The Review and the Booklet are published in evennumbered years. This edition is an updating through December 1995 (and, in some areas, well into 1996). As described in the section "Using Particle Physics Databases" following this introduction, the content of this Review is available on the World-Wide Web, and is updated between printed editions (http://pdg.lbl.gov/).

The Summary Tables give our best values of the properties of the particles we consider to be well established, a summary of search limits for hypothetical particles, and a summary of experimental tests of conservation laws.

The Particle Listings contain all the data used to get the values given in the Summary Tables. Other measurements considered recent enough or important enough to mention, but which for one reason or another are not used to get the best values, appear separately just beneath the data we do use for the Summary Tables. The Particle Listings also give information on unconfirmed particles and on particle searches, as well as short "reviews" on subjects of particular interest or controversy.

The Particle Listings were once an archive of all published data on particle properties. This is no longer possible because of the large quantity of data. We refer interested readers to earlier editions for data now considered to be obsolete.

We organize the particles into six categories:

Gauge and Higgs bosons

Leptons

Quarks

Mesons

Baryons

Searches for monopoles,

supersymmetry, compositeness, etc.

The last category only includes searches for particles that do not belong to the previous groups; searches for heavy charged leptons and massive neutrinos, by contrast, are with the leptons.

In Sec. 2 of this Introduction, we list the main areas of responsibility of the authors, and also list our large number of consultants, without whom we would not have been able to produce this *Review*. In Sec. 3, we mention briefly the naming scheme for hadrons. In Sec. 4, we discuss our procedures for choosing among measurements of particle

properties and for obtaining best values of the properties from the measurements.

The accuracy and usefulness of this *Review* depend in large part on interaction between its users and the authors. We appreciate comments, criticisms, and suggestions for improvements of any kind. Please send them to the appropriate author, according to the list of responsibilities in Sec. 2 below, or to the LBNL addresses below.

To order a copy of the *Review* or the *Particle Physics Booklet* from North and South America, Australia, and the Far East, write to

Particle Data Group, MS 50-308 Lawrence Berkeley National Laboratory Berkeley, CA 94720, USA or send e-mail to PDG@LBL.GOV.

To order more than one copy of the *Review* or booklet, write to

c/o Anne Fleming
Technical Information Division, MS 50B-4206

 $Technical\ support$

B. Armstrong, P.S. Gee

The Particle Data Group benefits greatly from the assistance of some 700 physicists who are asked to verify every piece of data entered into this *Review*. Of special value is the advice of the PDG Advisory Committee which meets annually and thoroughly reviews all aspects of our operation. The members of the 1995 committee were:

W.D. Schlatter (CERN), Chair

A. Ali (DESY)

D. Besson (University of Kansas)

P. Kreitz (SLAC)

M. Turner (Fermilab)

We have especially relied on the expertise of the following people for advice on particular topics:

- L. Addis (SLAC)
- S.I. Alekhin (COMPAS Group, IHEP, Serpukhov)
- A. Ali (DESY)
- J. Annala (Fermilab)
- J.N. Bahcall (Institute for Advanced Study)
- R. Bailey (CERN)
- B.C. Barish (Caltech)
- T. Barnes (University of Tennessee)
- O. Beibel (RWTH, Aachen)
- D. Besson (University of Kansas)
- S. Bilenky (Joint Inst. for Nuclear Research, Dubna)
- M. Billing (Cornell University)
- A. Blondel (Ecole Polytechnique)
- T. Bolton (Kansas State University)
- E. Browne (LBNL)
- A. Buras (Tech. University of Münich)
- P. Burrows (SLAC)
- R.N. Cahn (LBNL)

- M. Chanowitz (LBNL)
- Z. Chuang (IHEP, Beijing)
- E.D. Commins (University of California, Berkeley)
- O. Dahl (LBNL)
- R.H. Dalitz (Oxford University)
- S. Dawson (Brookhaven)
- L. Di Ciaccio (Rome University)
- M. Dine (University of California, Santa Cruz)
- R.J. Donoghue (LBNL)
- J. Dorfan (SLAC)
- J. Ellis (CERN)
- J. Erler (University of California, Santa Cruz)
- L.R. Evans (CERN)
- V.V. Ezhela (COMPAS Group, IHEP, Serpukhov)
- A. Fassó (CERN)
- R.W. Fast (Fermilab)
- W. Fetscher (ETH, Zürich)
- B.B. Filimonov (COMPAS Group, IHEP, Serpukhov)
- E. Fischbach (Purdue University)
- R. Flores (University of Minnesota)
- G. Fogli (University of Bari)
- S. Freedman (LBNL and UC, Berkeley)
- M. Fukugita (Yukawa Institute for Theo. Phys., Kyoto)
- T.K. Gaisser (Bartol Research Inst., Univ. of Delaware)
- J. Gasser (University of Bern)
- S. Geer (Fermilab)

3. Naming scheme for hadrons

We introduced in the 1986 edition [2] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of u, d, and s quarks. Otherwise, the only important change to known hadrons was that the F^{\pm} became the D_s^{\pm} . None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\bar{c}$ or $b\bar{b}$ mesons (we do, however, now use χ_c for the $c\bar{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

The scheme is described in "Naming Scheme for Hadrons" (p. 76) of this *Review*.

We give here our conventions on type-setting style. Particle symbols are italic (or slanted) characters: e^- , p, Λ , π^0 , K_L , D_s^+ , b. Charge is indicated by a superscript: B^- , Δ^{++} . Charge is not normally indicated for p, n, or the quarks, and is optional for neutral isosinglets: η or η^0 . Antiparticles and particles are distinguished by charge for charged leptons and mesons: τ^+ , K^- . Otherwise, distinct antiparticles are indicated by a bar (overline): $\overline{\nu}_\mu$, \overline{t} , \overline{p} , \overline{K}^0 , and $\overline{\Sigma}^+$ (the antiparticle of the Σ^-).

4. Procedures

4.1. Selection and treatment of data: The Particle Listings contain all relevant data known to us that are published in journals. With very few exceptions, we do not include results from preprints or conference reports. Nor do we include data that are of historical importance only (the Listings are not an archival record). We search every volume of 20 journals through our cutoff date for relevant data. We also include later published papers that are sent to us by the authors (or others).

In the Particle Listings, we clearly separate measurements that are used to calculate or estimate values given in the Summary Tables from measurements that are not used. We give explanatory comments in many such cases. Among the reasons a measurement might be excluded are the following:

- It is superseded by or included in later results.
- No error is given.
- It involves assumptions we question.
- It has a poor signal-to-noise ratio, low statistical significance, or is otherwise of poorer quality than other data available.

- It is clearly inconsistent with other results that appear to be more reliable. Usually we then state the criterion, which sometimes is quite subjective, for selecting "more reliable" data for averaging. See Sec. 4.
- It is not independent of other results.
- It is not the best limit (see below).
- It is quoted from a preprint or a conference report.

In some cases, *none* of the measurements is entirely reliable and no average is calculated. For example, the masses of many of the baryon resonances, obtained from partial-wave analyses, are quoted as estimated ranges thought to probably include the true values, rather than as averages with errors. This is discussed in the Baryon Particle Listings.

For upper limits, we normally quote in the Summary Tables the strongest limit. We do not average or combine upper limits except in a very few cases where they may be re-expressed as measured numbers with Gaussian errors.

As is customary, we assume that particle and antiparticle share the same spin, mass, and mean life. The Tests of Conservation Laws table, following the Summary Tables, lists tests of CPT as well as other conservation laws.

We use the following indicators in the Particle Listings to tell how we get values from the tabulated measurements:

- OUR AVERAGE—From a weighted average of selected data.
- OUR FIT—From a constrained or overdetermined multiparameter fit of selected data.
- OUR EVALUATION—Not from a direct measurement, but evaluated from measurements of related quantities.
- OUR ESTIMATE—Based on the observed range of the data. Not from a formal statistical procedure.
- OUR LIMIT—For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

An experimentalist who sees indications of a particle will of course want to know what has been seen in that region in the past. Hence we include in the Particle Listings all reported states that, in our opinion, have sufficient statistical merit and that have not been disproved by more reliable data. However, we promote to the Summary Tables only those states that we feel are well established. This judgment is, of course, somewhat subjective and no precise criteria can be given. For more detailed discussions, see the minireviews in the Particle Listings.

- **4.2.** Averages and fits: We divide this discussion on obtaining averages and errors into three sections:
- (1) treatment of errors; (2) unconstrained averaging;
- (3) constrained fits.

4.2.1. Treatment of errors: In what follows, the "error" δx means that the range $x \pm \delta x$ is intended to be a 68.3% confidence interval about the central value x. We treat this error as if it were Gaussian. Thus when the error is Gaussian, δx is the usual one standard deviation (1σ) . Many experimenters now give statistical and systematic errors separately, in which case we usually quote both errors, with the statistical error first. For averages and fits, we then add the the two errors in quadrature and use this combined error for δx .

When experimenters quote asymmetric errors $(\delta x)^+$ and $(\delta x)^-$ for a measurement x, the error that we use for that measurement in making an average or a fit with other measurements is a continuous function of these three quantities. When the resultant average or fit \overline{x} is less than $x-(\delta x)^-$, we use $(\delta x)^-$; when it is greater than $x+(\delta x)^+$, we use $(\delta x)^+$. In between, the error we use is a linear function of x. Since the errors we use are functions of the result, we iterate to get the final result. Asymmetric output errors are determined from the input errors assuming a linear relation between the input and output quantities.

In fitting or averaging, we usually do not include correlations between different measurements, but we try to select data in such a way as to reduce correlations. Correlated errors are, however, treated explicitly when there are a number of results of the form $A_i \pm \sigma_i \pm \Delta$ that have identical systematic errors Δ . In this case, one can first average the $A_i \pm \sigma_i$ and then combine the resulting statistical error with Δ . One obtains, however, the same result by averaging $A_i \pm (\sigma_i^2 + \Delta_i^2)^{1/2}$, where $\Delta_i = \sigma_i \Delta [\sum (1/\sigma_j^2)]^{1/2}$. This procedure has the advantage that, with the modified systematic errors Δ_i , each measurement may be treated as independent and averaged in the usual way with other data. Therefore, when appropriate, we adopt this procedure. We tabulate Δ and invoke an automated procedure that computes Δ_i before averaging and we include a note saying that there are common systematic errors.

Another common case of correlated errors occurs when experimenters measure two quantities and then quote the two and their difference, e.g., m_1 , m_2 , and $\Delta = m_2 - m_1$. We cannot enter all of m_1 , m_2 and Δ into a constrained fit because they are not independent. In some cases, it is a good approximation to ignore the quantity with the largest error and put the other two into the fit. However, in some cases correlations are such that the errors on m_1 , m_2 and Δ are comparable and none of the three values can be ignored. In this case, we put all three values into the fit and invoke an automated procedure to increase the errors prior to fitting such that the three quantities can be treated as independent measurements in the constrained fit. We include a note saying that this has been done.

4.2.2. Unconstrained averaging: To average data, we use a standard weighted least-squares procedure and in some cases, discussed below, increase the errors with a "scale factor." We begin by assuming that measurements of a given quantity are uncorrelated, and calculate a weighted average and error as

$$\overline{x} \pm \delta \overline{x} = \frac{\sum_{i} w_i \ x_i}{\sum_{i} w_i} \pm \left(\sum_{i} w_i\right)^{-1/2} , \qquad (1)$$

where

$$w_i = 1/(\delta x_i)^2 .$$

Here x_i and δx_i are the value and error reported by the ith experiment, and the sums run over the N experiments. We then calculate $\chi^2 = \sum w_i(\overline{x} - x_i)^2$ and compare it with N-1, which is the expectation value of χ^2 if the measurements are from a Gaussian distribution.

If $\chi^2/(N-1)$ is less than or equal to 1, and there are no known problems with the data, we accept the results.

If $\chi^2/(N-1)$ is very large, we may choose not to use the average at all. Alternatively, we may quote the calculated average, but then make an educated guess of the error, a conservative estimate designed to take into account known problems with the data.

Finally, if $\chi^2/(N-1)$ is greater than 1, but not greatly so, we still average the data, but then also do the following:

(a) We increase our quoted error, $\delta\overline{x}$ in Eq. (1), by a scale factor S defined as

$$S = \left[\chi^2/(N-1)\right]^{1/2} \ . \tag{2}$$

Our reasoning is as follows. The large value of the χ^2 is likely to be due to underestimation of errors in at least one of the experiments. Not knowing which of the errors are underestimated, we assume they are all underestimated by the same factor S. If we scale up all the input errors by this factor, the χ^2 becomes N-1, and of course the output error $\delta \overline{x}$ scales up by the same factor. See Ref. 3.

When combining data with widely varying errors, we modify this procedure slightly. We evaluate S using only the experiments with smaller errors. Our cutoff or ceiling on δx_i is arbitrarily chosen to be

$$\delta_0 = 3N^{1/2} \, \delta \overline{x} \, ,$$

where $\delta \overline{x}$ is the unscaled error of the mean of all the experiments. Our reasoning is that although the low-precision experiments have little influence on the values \overline{x} and $\delta \overline{x}$, they can make significant contributions to the χ^2 , and the contribution of the high-precision experiments thus tends to be obscured. Note that if each experiment has the same error δx_i , then $\delta \overline{x}$ is $\delta x_i/N^{1/2}$, so each δx_i is well below the cutoff. (More often, however, we simply exclude measurements with relatively large errors from averages and fits: new, precise data chase out old, imprecise data.)

Our scaling procedure has the property that if there are two values with comparable errors separated by much more than their stated errors (with or without a number of other values of lower accuracy), the scaled-up error $\delta \overline{x}$ is approximately half the interval between the two discrepant values.

We emphasize that our scaling procedure for *errors* in no way affects central values. And if you wish to recover the unscaled error $\delta \overline{x}$, simply divide the quoted error by S.

(b) If the number M of experiments with an error smaller than δ_0 is at least three, and if $\chi^2/(M-1)$ is greater than 1.25, we show in the Particle Listings an ideogram of the data. Fig. 1 is an example. Sometimes one or two data points lie apart from the main body; other times the data split into two or more groups. We extract no numbers from these ideograms; they are simply visual aids, which the reader may use as he or she sees fit.

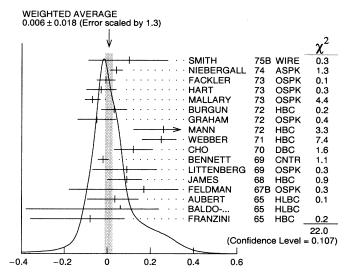

Figure 1: A typical ideogram. The arrow at the top shows the position of the weighted average, while the width of the shaded pattern shows the error in the average after scaling by the factor S. The column on the right gives the χ^2 contribution of each of the experiments. Note that the next-to-last experiment, denoted by the incomplete error flag (\bot) , is not used in the calculation of S (see the text).

Each measurement in an ideogram is represented by a Gaussian with a central value x_i , error δx_i , and area proportional to $1/\delta x_i$. The choice of $1/\delta x_i$ for the area is somewhat arbitrary. With this choice, the center of gravity of the ideogram corresponds to an average that uses weights $1/\delta x_i$ rather than the $(1/\delta x_i)^2$ actually used in the averages. This may be appropriate when some of the experiments have seriously underestimated systematic errors. However, since for this choice of area the height of the Gaussian for each measurement is proportional to $(1/\delta x_i)^2$, the peak position of the ideogram will often favor the high-precision measurements at least as much as does the least-squares average. See our 1986 edition [2] for a detailed discussion of the use of ideograms.

4.2.3. Constrained fits: Except for trivial cases, all branching ratios and rate measurements are analyzed by making a simultaneous least-squares fit to all the data and extracting the partial decay fractions P_i , the partial widths Γ_i , the full width Γ (or mean life), and the associated error matrix.

Assume, for example, that a state has m partial decay fractions P_i , where $\sum P_i = 1$. These have been measured in N_r different ratios R_r , where, e.g., $R_1 = P_1/P_2$, $R_2 = P_1/P_3$, etc. [We can handle any ratio R of the form $\sum \alpha_i P_i/\sum \beta_i P_i$, where α_i and β_i are constants, usually 1 or 0. The forms $R = P_i P_j$ and $R = (P_i P_j)^{1/2}$ are also allowed.] Further assume that each ratio R has been measured by N_k experiments (we designate each experiment with a subscript k, e.g., R_{1k}). We then find the best values of the fractions P_i by minimizing the χ^2 as a function of the m-1 independent parameters:

$$\chi^2 = \sum_{r=1}^{N_r} \sum_{k=1}^{N_k} \left(\frac{R_{rk} - R_r}{\delta R_{rk}} \right)^2 , \qquad (3)$$

where the R_{rk} are the measured values and R_r are the fitted values of the branching ratios.

In addition to the fitted values \overline{P}_i , we calculate an error matrix $\langle \delta \overline{P}_i \ \delta \overline{P}_j \rangle$. We tabulate the diagonal elements of $\delta \overline{P}_i = \langle \delta \overline{P}_i \ \delta \overline{P}_i \rangle^{1/2}$ (except that some errors are scaled as discussed below). In the Particle Listings, we give the complete correlation matrix; we also calculate the fitted value of each ratio, for comparison with the input data, and list it above the relevant input, along with a simple unconstrained average of the same input.

Three comments on the example above:

- (1) There was no connection assumed between measurements of the full width and the branching ratios. But often we also have information on partial widths Γ_i as well as the total width Γ . In this case we must introduce Γ as a parameter in the fit, along with the P_i , and we give correlation matrices for the widths in the Particle Listings.
- (2) We do not allow for correlations between input data. We do try to pick those ratios and widths that are as independent and as close to the original data as possible. When one experiment measures all the branching fractions and constrains their sum to be one, we leave one of them (usually the least well-determined one) out of the fit to make the set of input data more nearly independent.
- (3) We calculate scale factors for both the R_r and P_i when the measurements for any R give a larger-than-expected contribution to the χ^2 . According to Eq. (3), the double sum for χ^2 is first summed over experiments k=1 to N_k , leaving a single sum over ratios $\chi^2 = \sum \chi_r^2$. One is tempted to define a scale factor for the ratio r as $S_r^2 = \chi_r^2/\langle \chi_r^2 \rangle$. However, since $\langle \chi_r^2 \rangle$ is not a fixed quantity (it is somewhere between N_k and N_{k-1}), we do not know how to evaluate this expression. Instead we define

$$S_r^2 = \frac{1}{N_k} \sum_{k=1}^{N_k} \frac{\left(R_{rk} - \overline{R}_r\right)^2}{(\delta R_{rk})^2 - (\delta \overline{R}_r)^2} , \qquad (4)$$

where $\delta \overline{R}_r$ is the fitted error for ratio r. With this definition the expected value of S_r^2 is one.

The fit is redone using errors for the branching ratios that are scaled by the larger of S_r and unity, from which new

and often larger errors $\delta \overline{P}'_i$ are obtained. The scale factors we finally list in such cases are defined by $S_i = \delta \overline{P}'_i/\delta \overline{P}_i$. However, in line with our policy of not letting S affect the central values, we give the values of \overline{P}_i obtained from the original (unscaled) fit.

There is one special case in which the errors that are obtained by the preceding procedure may be changed. When a fitted branching ratio (or rate) \overline{P}_i turns out to be less than three standard deviations $(\delta \overline{P}'_i)$ from zero, a new smaller error $(\delta \overline{P}''_i)^-$ is calculated on the low side by requiring the area under the Gaussian between $\overline{P}_i - (\delta \overline{P}''_i)^-$ and \overline{P}_i to be 68.3% of the area between zero and \overline{P}_i . A similar correction is made for branching fractions that are within three standard deviations of one. This keeps the quoted errors from overlapping the boundary of the physical region.

4.3. Discussion: The problem of averaging data containing discrepant values is nicely discussed by Taylor in Ref. 4. He considers a number of algorithms that attempt to incorporate inconsistent data into a meaningful average. However, it is difficult to develop a procedure that handles simultaneously in a reasonable way two basic types of situations: (a) data that lie apart from the main body of the data are incorrect (contain unreported errors); and (b) the opposite—it is the main body of data that is incorrect. Unfortunately, as Taylor shows, case (b) is not infrequent. He concludes that the choice of procedure is less significant than the initial choice of data to include or exclude.

We place much emphasis on this choice of data. Often we solicit the help of outside experts (consultants). Sometimes, however, it is simply impossible to determine which of a set of discrepant measurements are correct. Our scale-factor technique is an attempt to address this ignorance by increasing the error. In effect, we are saying that present experiments do not allow a precise determination of this quantity because of unresolvable discrepancies, and one must await further measurements. The reader is warned of this situation by the size of the scale factor, and if he or she desires can go back to the literature (via the Particle Listings) and redo the average with a different choice of data.

Our situation is less severe than most of the cases Taylor considers, such as estimates of the fundamental constants like h, etc. Most of the errors in his case are dominated by systematic effects. For our data, statistical errors are often at least as large as systematic errors, and statistical errors are usually easier to estimate. A notable exception occurs in partial-wave analyses, where different techniques applied to the same data yield different results. In this case, as stated earlier, we often do not make an average but just quote a range of values.

A brief history of early Particle Data Group averages is given in Ref. 3. Figure 0.2 shows some histories of our values of a few particle properties. Sometimes large changes occur. These usually reflect the introduction of significant new data or the discarding of older data. Older data are discarded in favor of newer data when it is felt that the newer data have smaller systematic errors, or have more checks on systematic errors, or have made corrections unknown at the time of the older experiments, or simply have much smaller errors. Sometimes, the scale factor becomes large near the time at which a large jump takes place, reflecting the uncertainty introduced by the new and inconsistent data.

By and large, however, a full scan of our history plots shows a dull progression toward greater precision at central values quite consistent with the first data points shown.

We conclude that the reliability of the combination of experimental data and our averaging procedures is usually good, but it is important to be aware that fluctuations outside of the quoted errors can and do occur.

ACKNOWLEDGMENTS

The publication of the Review of Particle Physics is supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, the Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098; by the U.S. National Science Foundation under Agreement No. PHY-9320551; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development; and by the Italian National Institute of Nuclear Physics (INFN).

We thank all those who have assisted in the many phases of preparing this *Review*. We particularly thank the many who have responded to our requests for verification of data entered in the Listings, and those who have made suggestions or pointed out errors. The CERN group wishes to thank Andrew Hicks for his technical help.

Revised by P. Kreitz, May 1996

The purpose of this list is to organize a broad set of online catalogs, databases, directories, World-Wide Web (WWW) pages, etc., that are of value to the particle physics physics community. While a substantial amount of particle physics physics information is computer accessible through the Internet's World-Wide Web, most listings do not provide descriptions of a resource's scope and content so that searchers know which source to use for a specific information need. This compilation lists the main information sources with brief annotations and basic Internet WWW addresses (URL's). Because this list must be fixed in print, it is important to consult the updated version of this compilation which includes newly added resources and hypertext links to more complete information at:

http://www.slac.stanford.edu/library/pdg/hepinfo.html

In this edition, a resource is excluded if it provides information primarily of interest to one institution. In some cases, multiple databases covering much the same material have been included with the assumption that users will make subsequent choices based on Internet speeds, search system interfaces, or differences in scope, presentation, and coverage. Databases and resources focusing primarily on accelerator physics have been excluded in deference to the excellent compilation at the World Wide Web Virtual Library of Accelerator Physics:

http://beam.slac.stanford.edu/www/library/w3/alab.htmlx

Please send suggestions, additions, changes, ideas for category groupings, exclusions, etc., via the WWW form linked to the URL above, or by e-mail to pkreitz@slac.stanford.edu.

1. Particles & Properties Data:

• REVIEW OF PARTICLE PHYSICS (RPP): A comprehensive review of the field of Particle Physics produced by the Particle Data Group (PDG). Includes a compilation/evaluation of data on particle properties, summary tables with best values and limits for particle properties, extensive summaries of searches for hypothetical particles, and a long section of reviews, tables, and plots on a wide variety of theoretical and experimental topics of interest to particle and astrophysicists. The linked table of contents provides access to particle listings, reviews, summary tables, errata, indices, etc. The current printed version is Physical Review D54, xxx (1996). Maintained at:

http://pdg.lbl.gov/

• PARTICLE PHYSICS BOOKLET: An extract from the most recent edition of the full Review of Particle Physics. Contains images in an easy-to-read print useful for classroom studies:

http://pdg.lbl.gov/rpp/booklet/contents.html

• PARTICLE PROPERTIES Database: Durham/RAL provides a simple index to the PDG particle properties information contained in the Review of Particle Physics. Maintained at:

http://durpdg.dur.ac.uk/HEPDATA/PART

• PARTICLE PHYSICS INTERACTIVE DATABASE: A searchable database containing information from the Review of Particle Physics. Updated around summer of every year. Available by telnet as follows:

Telnet: //pdg_public@muse.lbl.gov/ (User name PDG_PUBLIC, no password).

• COMPUTER-READABLE FILES: Currently available from the PDG: tables of masses, widths, and PDG Monte Carlo particle numbers and cross section data, including hadronic total and elastic cross sections vs laboratory momenta and total center-of-mass energy. Overview page at:

http://pdg.lbl.gov/computer_read.html

 PARTICLE PHYSICS DATA SYSTEM: Maintained by the COM-PAS group at IHEP, this system, currently under construction, provides an online version of the Guide to Experimental Elementary Particle Physics Literature (1895–1995). Permits searching by author, title, accelerator, detector, reaction, particle, etc. For research from 1950 to the present, it will provide online searching of compilations of integrated cross sections data and numerical data on observables in reactions. Also provides a chronology of key events in particle physics:

http://muse.lbl.gov:8001/ppds.html

• REACTION DATA: A part of the HEPDATA databases at Durham/RAL, this database is a collaboration of Durham and the COMPAS Group for the PDG. Contains numerical values of cross sections, structure, functions, polarizations, etc.:

http://durpdg.dur.ac.uk/HEPDATA/REAC

• PHYSICS AROUND THE WORLD: DATA AND TABLES: Includes links to periodic tables of elements, laws and constants, scales of measurement, particle and nuclear data, equations, and (peripheral) "more data and tables:"

http://www.physics.mcgill.ca:8081/ physics-services/physics_tables.html

2. Collaborations & Experiments:

• EXPERIMENTS Database: Contains more than 1,800 experiments in elementary particle physics. Search and browse by author; title; experiment number or prefix; institution; date approved, started or completed; accelerator or detector; polarization, reaction, final state or particle; or by papers produced. Maintained at SLAC for the LBNL Particle Data Group. Supplies the information for "Current Experiments in Particle Physics (LBL-91)." Updated every second year (next: Summer 1996):

 $\verb|http://www-spires.slac.stanford.edu/find/experiments|$

• EXPERIMENTS ONLINE: Home Pages of HEP Experiments: A list from SLAC of accelerator and non-accelerator experiments with an active link to each home page. Accelerator experiments are organized by institution, machine, and experiment name:

 $\verb|http://www-spires.slac.stanford.edu/find/explist.html|$

• HIGH ENERGY PHYSICS EXPERIMENTS: A HEPNET page providing links to HEP collaborations around the world. List arranged alphabetically by collaboration name:

http://www.hep.net/experiments/collabs.html

3. Conferences:

CONFERENCES: Contains conferences, schools, and meetings of
interest to high-energy physicists. Searchable database produced
jointly by the SLAC and DESY libraries of over 5,000 listings
covering 1973 to 1999+. Search or browse by title, acronym, date,
location. Includes links to the conference home page, information
about published proceedings, links to submitted papers from the
SPIRES-HEP database, and links to the electronic versions of the
papers if available:

http://www-spires.slac.stanford.edu/ spires/form/confspif.html

• CONFERENCES, WORKSHOPS, AND SUMMER SCHOOLS: By The Internet Pilot to Physics. Several hundred listings, including those for regional meetings of national societies and meetings of ancillary groups such as physics teachers. Provides a WWW form for adding a conference, and automatically uploads new entries to the EPS EurophysNet meeting list.

http://www.tp.umu.se/TIPTOP/FORUM/CONF/

• CONFNEWS: Provides listings of current and future conferences divided by subfield or by region. Also provides links to WWW conference pages and an e-mail interface (robot@physics.umd.edu with CONFMENU in the subject line):

http://www.physics.umd.edu/robot/confer/confmenu.html

• EUROPHYSICS Meetings List: Meta-level list of other conference lists with active links to the URL of the organization's meeting calendar, the conference database, etc. Useful for searching by organization, providing access to meetings and conferences that are of interest, but not central to high-energy physics. Maintained by the European Physical Society but international in scope. Organized alphabetically by the name of the resource or organization:

http://epswww.epfl.ch/conf/urls.html

• HEP EVENTS: A list maintained by CERN of upcoming conferences, schools, workshops, seminars, and symposia of interest to high-energy physics organized by type of meeting, e.g. school, workshop:

http://www.cern.ch/Physics/Conferences

• PHYSICS CONFERENCE ANNOUNCEMENTS by Thread: Lists current year's conference announcements with links to WWW pages. Posting is voluntary, which is perhaps why this resource lacks the breadth of other databases covering conferences:

http://xxx.lanl.gov/Announce/Conference/

4. Current Notices & Announcement Services:

• CONFERENCES, WORKSHOPS, AND SUMMER SCHOOLS: By The Internet Pilot to Physics. Provides a Web form for adding a conference and automatically uploads new entries to the EPS EurophysNet meeting list.

http://www.tp.umu.se/TIPTOP/FORUM/CONF/

- CONFNEWS & WEBNEWS: Provides a system for broadcasting a conference or job opening to "a large number of physicists worldwide." For further information, e-mail: kim@umdhep.umd.edu
- E-PRINT ARCHIVES: The LANL-based E-Print Archives provides daily notices of what new high-energy physics preprints have been submitted to the archives as full text electronic documents. Use the WWW-accessible listings:

http://xxx.lanl.gov/

or subscribe:

http://xxx.lanl.gov/help/e-help

(under "Description of e-Mail Commands") to receive the automatic e-mail notices. Covers over two dozen subfields of high-energy physics, and provides active links to abstracts and full text versions of the preprints.

Note: Use the library pages below to find information on recently received books and proceedings. Use the online table of contents listings below to find journal table of contents. Conference announcements can also be sent via e-mail to most of the conference database providers listed above who often supply their e-mail address at the bottom of their Web page.

5. Directories:

5.1. Directories - Organizations:

• DIRECTORY OF RESEARCH INSTITUTES in High Energy Physics: Maintained by CERN and organized into three alphabetical lists by country, town, and institutional name. Provides addresses, and, where available, the following: phone and fax numbers; e-mail addresses; active URL links; and information about the institution's physics program:

http://preprints.cern.ch/institutes/welcome.html

 HEP INSTITUTIONS ONLINE: Active links to the home pages of more than 200 HEP-related institutions with WWW servers. Maintained by SLAC and organized by country, and then alphabetically by institution:

http://www-spires.slac.stanford.edu/find/instlink.html

 INSTITUTIONS: Database of over 5,000 high-energy physics Institutes, Laboratories, and University departments in which some research on elementary particle physics is performed. Covers six continents and almost one hundred countries, and is searchable by name, acronym, location, *etc.* Provides address, phone and fax numbers, and e-mail and URL addresses where available. Has pointers to the recent HEP papers from an institution. Maintained by SLAC:

http://www-spires.slac.stanford.edu/ spires/form/instspif.html

PHYSICS: High-Energy Physics and Nuclear Physics Labs: This
list of WWW home pages is usefully arranged into accelerator
labs by country, research groups at universitites, and national
and international institutes. The theoretical physics section is
thin. Part of a larger effort maintained by Physics Around the
World/TIPTOP to organize physics-related institutions by field of
research:

http://www.physics.mcgill.ca:8081/ physics-services/physics_hep_labs.html

5.2. Directories - People:

 HEPNAMES: Searchable database of 25,500 e-mail addresses of people related to high-energy physics. Access by individual name, and, in the near future, by institution or place.

http://www-spires.slac.stanford.edu/find/hepnames

This site is mirrored at Durham under a different name (EMAIL-ID) and with a search interface written and maintained by Durham:

http://durpdg.dur.ac.uk/HEPDATA/ID

• HEP VIRTUAL PHONEBOOK: A list of links to phonebooks and directories of high-energy physics sites around the world. Maintained by HEPNET:

http://www.hep.net/sites/directories.html

${\bf 5.3.} \quad {\bf Directories-Publishers:}$

 PHYSICS AROUND THE WORLD: A page of active links to institutions, societies, or companies involved in supplying physicsrelated information. Organized into sections, the most useful of which are: Preprint Archives, Journals, Magazines, Newsletters, Publishers, and Books:

http://www.physics.mcgill.ca:8081/ physics-services/physics_publ2.html

6. E-Prints/Pre-Prints, Papers & Reports:

• ALICE: The CERN Library's database which contains citations to more than 190,000 monographs, series, preprints and official committee documents held by the Library or the Archives:

http://wwwas.cern.ch/ASinfo/AS-SI/alice/ALICE.html

Also provides links to CERN's full text preprint server:

http://preprints.cern.ch/.

• HEP DATABASE (SLAC/SPIRES): Contains over 300,000 bibliographic summaries for particle physics papers (e-prints, journal articles, preprints, reports, theses, etc.). Covers 1974 to the present and is updated daily with links to electronic texts (e.g. from LANL, CERN, KEK, and other HEP servers). Searchable by all authors and authors' affiliations, title, topic, report number, citation, e-print archive number, date, etc: A joint project of the SLAC and DESY libraries with the collaboration of many other institutions including APS, Fermilab, and Kyoto.

http://www-spires.slac.stanford.edu/find/hep

 KISS: KEK preprint database, contains bibliographic records of preprints and technical reports held in the KEK library with links to the full text images of over 90,000 items in their collection:

http://keklib.kek.jp/KISS.v2/kiss_prepri.html

• LANL E-PRINT ARCHIVES: An automated electronic repository of physics preprints, primarily in the subfields of high-energy physics, but also in other physics fields such as chemical, nuclear, condensed matter, etc. Began with a core set of subfield archives in 1991. Provides access to the full text of the electronic versions of these preprints, and permits searching by author, title, key word in abstract, and by limiting by subfield archive or by date. Papers are sent electronically to the archives by the author:

http://xxx.lanl.gov

• DOCUMENTS: (IHEP-COMPAS/PDG) A database providing the source information for the print publication "A Guide to Experimental Elementary Particle Physics Literature" (LBL-90). Provides bibliographic summaries of experimental papers which report new experimental data and theoretical papers which extract new information from experiments. Excludes instrumentation and papers mainly of interest only to nuclear physicists. Coverage is from 1895 to the present:

http://muse.lbl.gov:8001/ppds.html

Gauge & Higgs Boson Summary Table

Higgs Bosons — H^0 and H^\pm , Searches for H^0 Mass m > 58.4 GeV, CL = 95% H^0_1 in Supersymmetric Models ($m_{H^0_1} < m_{H^0_2}$) [J] Mass m > 44 GeV, CL = 95% A^0 Pseudoscalar Higgs Boson in Supersymmetric Models [J] Mass m > 24.3 GeV, CL = 95% $\tan \beta > 1$, $m_t < 200$ GeV H^\pm Mass m > 43.5 GeV, CL = 95%

See the Particle Listings for a Note giving details of Higgs Bosons.

Heavy Bosons Other Than Higgs Bosons, Searches for

Additional W Bosons

```
W_R — right-handed W Mass m>406 GeV, CL = 90% (assuming light right-handed neutrino) W' with standard couplings decaying to e\nu, \mu\nu Mass m>652 GeV, CL = 95%
```

Additional Z Bosons

```
\boldsymbol{Z}_{\text{SM}}^{\prime} with standard couplings
  Mass m > 505 GeV, CL = 95%
                                            (pp direct search)
   Mass m > 779 GeV, CL = 95%
                                            (electroweak fit)
Z_{LR} of SU(2)_L \times SU(2)_R \times U(1)
   (with g_L = g_R)
   Mass m > 445 GeV, CL = 95%
                                            (p\overline{p} \text{ direct search})
   Mass m > 389 GeV, CL = 95%
                                            (electroweak fit)
Z_{\chi} of SO(10) \rightarrow SU(5)\timesU(1)\chi
   (coupling constant derived from G.U.T.)
   Mass m > 425 GeV, CL = 95\%
                                            (p\overline{p} \text{ direct search})
   Mass m > 321 GeV, CL = 95%
                                            (electroweak fit)
Z_{\psi} of E_6 \rightarrow SO(10) \times U(1)_{\psi}
   (coupling constant derived from G.U.T.)
                                           (p\overline{p} \text{ direct search})
   Mass m > 415 GeV, CL = 95%
   Mass m > 160 GeV, CL = 95\%
Z_{\eta} of E_6 \rightarrow SU(3)\times SU(2)\times U(1)\times U(1)_{\eta}
   (coupling constant derived from G.U.T.);
   charges are Q_{\eta}=\sqrt{3/8}Q\chi-\sqrt{5/8}Q_{\psi})
   Mass m > 440 GeV, CL = 95% (p\overline{p} direct search)
   Mass m > 182 GeV, CL = 95\% (electroweak fit)
```

Scalar Leptoquarks

```
Mass m>116 GeV, CL = 95% (1st generation, pair prod.) Mass m>230 GeV, CL = 95% (1st gener., single prod.) Mass m>97 GeV, CL = 95% (2nd gener., pair prod.) Mass m>73 GeV, CL = 95% (2nd gener., single prod.) Mass m>45 GeV, CL = 95% (3rd gener., pair prod.) (The second, fourth, and fifth limits above are for charge -1/3, weak isoscalar.)
```

Axions (A⁰) and Other Very Light Bosons, Searches for

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $> 7.2 \times 10^{24}$ years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b] ℓ indicates each type of lepton (e, μ , and τ), not sum over them.
- [c] The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.
- [d] This partial width takes into account Z decays into $\nu\overline{\nu}$ and any other possible undetected modes.
- [e] This ratio has not been corrected for the au mass.
- [f] Here $A \equiv 2g_V g_A/(g_V^2+g_A^2)$.
- [g] The value is for the sum of the charge states of particle/antiparticle states indicated.
- [h] See the ${\it Z}$ Particle Listings for the γ energy range used in this measurement.
- [i] For $m_{\gamma\gamma}=$ (60 \pm 5) GeV.
- [j] The limits assume no invisible decays.

Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes (in the modes below, ℓ means a sum over e and μ modes)

L means lepton number violation (e.g. $\tau^- \to e^+\pi^-\pi^-$). Following common usage, LF means lepton family violation and not lepton number violation (e.g. $\tau^- \to e^-\pi^+\pi^-$).

violation (e.g. 1 →	е и и	٦٠				
$e^-\gamma$	LF	<	1.1	$\times 10^{-4}$	CL=90%	888
$\mu^- \gamma$	LF	<	4.2	\times 10 ⁻⁶	CL=90%	885

Heavy Charged Lepton Searches

 L^\pm – charged lepton Mass m>42.7 GeV, CL =95% $m_{\nu}\approx0$ L^\pm – stable charged heavy lepton Mass m>42.8 GeV, CL =95%

Neutrinos

See the Particle Listings for a Note giving details of neutrinos, masses, mixing, and the status of experimental searches.

$$J=\frac{1}{2}$$

Mass m: Unexplained effects have resulted in significantly negative m^2 in the new, precise tritium beta decay experiments. It is felt that a real neutrino mass as large as 10-15 eV would cause observable spectral distortions even in the presence of the end-point count excesses.

Mean life/mass, $\tau/m_{\nu_e}>300$ s/eV, CL =90% Magnetic moment $\mu<1.8\times10^{-10}~\mu_B$, CL =90%

$$J = \frac{1}{8}$$

Mass m<0.17 MeV, CL = 90% Mean life/mass, $\tau/m_{\nu_{\mu}}>15.4$ s/eV, CL = 90% Magnetic moment $\mu<7.4\times10^{-10}~\mu_{B}$, CL = 90% $u_{ au}$

$$J=\frac{1}{2}$$

Mass m < 24 MeV, CL = 95% Magnetic moment $\mu < 5.4 \times 10^{-7}~\mu_{B}$, CL = 90%

Number of Light Neutrino Types

Massive Neutrinos and Lepton Mixing, Searches for

For excited leptons, see Compositeness Limits below.

See the Particle Listings for a Note giving details of neutrinos, masses, mixing, and the status of experimental searches.

No direct, uncontested evidence for massive neutrinos or lepton mixing has been obtained. Sample limits are:

```
Mass m > 45.0, CL = 95% (Dirac)
Mass m > 39.5, CL = 95% (Majorana)
```

u oscillation: $u_{\mu} \rightarrow u_{e} (\theta = \text{mixing angle})$

```
Mass m>19.6 GeV, CL = 95% (all |U_{\ell j}|^2) (Dirac) Mass m>45.7 GeV or m<25, CL = 95% (|U_{\ell j}|^2>10^{-13} (Dirac)
```

ν oscillation: $\overline{\nu}_e \not \rightarrow \overline{\nu}_e$

$$\Delta(m^2) < 0.0075 \text{ eV}^2, \text{ CL} = 90\% \quad (\text{if } \sin^2 2\theta = 1) \\ \sin^2 2\theta < 0.02, \text{ CL} = 90\% \quad (\text{if } \Delta(m^2) \text{ is large})$$

ν oscillation: $\nu_{\mu} \rightarrow \nu_{e}$ ($\theta = \text{mixing angle}$)

```
\begin{array}{lll} \Delta(m^2) &< 0.09 \; \text{eV}^2, \; \text{CL} = 90\% & (\text{if } \sin^2\!2\theta = 1) \\ \sin^2\!2\theta &< 2.5 \times 10^{-3}, \; \text{CL} = 90\% & (\text{if } \Delta(m^2) \; \text{is large}) \end{array}
```

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] The ucertainty in the electron mass in unified atomic mass units (u) is ten times smaller than that given by the 1986 CODATA adjustment, quoted in the Table of Physical Contants (Section 1). The conversion to MeV via the factor 931.49432(28) MeV/u is more uncertain because of the electron charge uncertainty. Our value in MeV differs slightly from the 1986 CODATA result.
- [b] This is the best "electron disappearance" limit. The best limit for the mode $e^-\to~\nu\gamma$ is $>2.35\times10^{25}$ yr (CL=68%).
- [c] The muon mass is most precisely known in u (unified atomic mass units). The conversion factor to MeV via the factor 931.49432(28) MeV/u is more uncertain because of the electron charge uncertainty.
- [d] See the "Note on Muon Decay Parameters" in the μ Particle Listings for definitions and details.
- [e] P_μ is the longitudinal polarization of the muon from pion decay. In standard V-A theory, $P_\mu=1$ and $\rho=\delta=3/4$.
- [f] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\,\nu_\mu$ and $e^-\overline{\nu}_e\,\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [g] See the μ Particle Listings for the energy limits used in this measurement.
- [h] A test of additive vs. multiplicative lepton family number conservation.
- [i] Basis mode for the τ .

Quark Summary Table

QUARKS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\rm MS}$ at a scale $\mu\approx 1$ GeV. The c- and b-quark masses are estimated from charmonium, bottomonium, D, and B masses. They are the "running" masses in the $\overline{\rm MS}$ scheme. These can be different from the heavy quark masses obtained in potential models.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

Mass m = 2 to 8 MeV [a] $m_u/m_d = 0.25$ to 0.70

Mass $m=180\pm12$ GeV (direct observation of top events) Mass $m=179\pm8^{+17}_{-20}$ GeV (Standard Model electroweak fit)

b' (4th Generation) Quark, Searches for

Mass m > 85 GeV, CL = 95% ($p\bar{p}$, charged current decays) Mass m > 46.0 GeV, CL = 95% (e^+e^- , all decays)

Free Quark Searches

All searches since 1977 have had negative results.

NOTES

[a] The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of u and d masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s-quark mass is estimated from SU(3) splittings in hadron masses.

LIGHT UNFLAVORED MESONS (S=C=B=0)

For I=1 $(\pi,\,b,\,\rho,\,a)$: $u\overline{d},\,(u\overline{u}-d\overline{d})/\sqrt{2},\,d\overline{u};$ for I=0 $(\eta,\,\eta',\,h,\,h',\,\omega,\,\phi,\,f,\,f')$: $c_1(u\overline{u}+d\overline{d})+c_2(s\overline{s})$

$$I^G(J^P)=\mathbf{1}^-(0^-)$$

Mass $m = 139.56995 \pm 0.00035 \text{ MeV}$ Mean life $\tau = (2.6033 \pm 0.0005) \times 10^{-8}$ s (S = 1.2) $c\tau = 7.8045 \text{ m}$

$\pi^{\pm} ightarrow \ell^{\pm} \nu \gamma$ form factors $^{[a]}$

 $F_V = 0.017 \pm 0.008$ $F_A = 0.0116 \pm 0.0016$ (S = 1.3) $R = 0.059^{\,+\,0.009}_{\,-\,0.008}$

BOTTOM MESONS

$$(B=\pm 1)$$

 $B^+=u\overline{b},\, B^0=d\overline{b},\, \overline{B}{}^0=\overline{d}\,b,\, B^-=\overline{u}\,b,\,$ similarly for B^* 's

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: " B^\pm/B^0 Admixture" for $\Upsilon(4S)$ results and " $B^\pm/B^0/B_S^0/B_S^0$ —baryon Admixture" for results at higher energies. Most inclusive decay branching fractions are found in the Admixture sections. $B^0-\overline{B}^0$ mixing data are found in the B^0 section, while $B_S^0-\overline{B}^0$ mixing data and $B-\overline{B}$ mixing data for a B^0/B_S^0 admixture are found in the B_S^0 section. CP-violation data are found in the B^0 section. B^0 -baryons are found near the end of the Baryon section.

The organization of the ${\it B}$ sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

$$I(J^P) = \frac{1}{2}(0^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass
$$m_{B^\pm}=5278.9\pm1.8~{\rm MeV}$$
 Mean life $\tau_{B^\pm}=(1.62\pm0.06)\times10^{-12}~{\rm s}$ $c au=462~{\rm \mu m}$

 B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE

The branching fractions listed below assume 50% $B^0\,\overline B{}^0$ and 50% $B^+\,B^$ production at the $\varUpsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\varUpsilon(4S)$ production ratio to 50:50 and their assumed $D,\,D_{\mathcal{S}},\,D^*$, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

B^{\pm}/B^0 ADMIXTURE

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $\mathsf{B}(\varUpsilon(4S)\to B\overline{B})=100\%$.

the $\Upsilon(4s)$. The values quoted assume that $B(\Upsilon(4s) \to BB) = 100\%$. For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

 $\overline{\cal B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE

These measurements are for an admixture of bottom particles at high energy (LEP, Tevatron, SppS).

Mean life
$$au=(1.549\pm0.020)\times10^{-12}$$
 s Mean life $au=(1.72\pm0.10)\times10^{-12}$ s Charged b -hadron admixture

Mean life
$$au = (1.58 \pm 0.14) imes 10^{-12}$$
 s Neutral b -hadron admixture

$$\tau_{\rm charged\ b-hadron}/\tau_{\rm neutral\ b-hadron}=1.09\pm0.13$$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $Sp\overline{p}S$) are used in the branching fraction averages. The production fractions give our best current estimate of the admixture at

For inclusive branching fractions, e.g., $B\to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections

The modes below are listed for a \overline{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include

T DECAY MODES

Fraction (Γ_i/Γ)

Confidence level (MeV/c)

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at the Z have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by O. Hayes (CERN) and M. Jimack (U. Birmingham) as described in the note "Production and Decay of b-Flavored Hadrons" in the B^\pm Particle Listings. Values assume

$$\begin{array}{ll} \mathsf{B}(\overline{b}\to B^+) = \mathsf{B}(\overline{b}\to B^0) \\ \mathsf{B}(\overline{b}\to B^+) + \mathsf{B}(\overline{b}\to B^0) + \mathsf{B}(\overline{b}\to B^0_s) + \mathsf{B}(b\to \Lambda_b) = 100 \, \%. \end{array}$$

The notation for production fractions varies in the literature (f_{B^0} , $f(b \rightarrow$ $\overline{\mathcal{B}}^0$), Br $(b \to \overline{\mathcal{B}}^0)$). We use our own branching fraction notation here, B $(\overline{b} \to \mathcal{B}^0)$.

В*

$$I(J^P) = \frac{1}{2}(1^-)$$

p (MeV/c)

I, J, P need confirmation. Quantum numbers shown are quark-model

Mass
$$m_{B^*} = 5324.8 \pm 1.8 \; {\rm MeV}$$
 $m_{B^*} - m_B = 45.7 \pm 0.4 \; {\rm MeV}$

B* DECAY MODES Fraction (Γ_i/Γ)

 $B\gamma$ dominant

BOTTOM, STRANGE MESONS $(B = \pm 1, S = \mp 1)$

 $B_s^0 = s\overline{b}$, $\overline{B}_s^0 = \overline{s}b$, similarly for B_s^* 's

 B_s^0

$$I(J^P) = 0(0^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model

Mass
$$m_{B_s^0} = 5369.3 \pm 2.0 \text{ MeV}$$

Mean life $\tau = (1.61^{+0.10}_{-0.09}) \times 10^{-12} \text{ s}$
 $c\tau = 483 \ \mu\text{m}$

$B_s^0 - \overline{B}_s^0$ mixing parameters

$$\begin{array}{l} \chi_s > 0.49, \; \mathrm{CL} = 95\% \\ \chi_B \; \mathrm{at \; high \; energy} = f_d \chi_d + f_s \chi_s = 0.126 \, \pm \, 0.008 \\ \Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0} > 5.9 \times 10^{12} \; \hbar \; \mathrm{s}^{-1}, \; \mathrm{CL} = 95\% \\ \chi_s = \Delta m_{B_s^0} / \Gamma_{B_s^0} > 9.5, \; \mathrm{CL} = 95\% \end{array}$$

These branching fractions all scale with B($\overline{b} \rightarrow B_s^0$), the LEP B_s^0 production fraction. The first four were evaluated using $B(\overline{b} \rightarrow B_s^0) =$ (11.2 + 1.8)% and the rest assume B($\bar{b} \to B_s^0$) = 12%.

The branching fraction B($B_s^0 \to D_s^- \ell^+ \nu_\ell$ anything) is not a pure measurement since the measured product branching fraction $B(\overline{b} \rightarrow B_s^0) \times$ $B(B_0^0 \to D_0^- \ell^+ \nu_\ell$ anything) was used to determine $B(\overline{b} \to B_0^0)$, as described in the note on "Production and Decay of b-Flavored Hadrons."

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] See the "Note on $\pi^\pm \to \ell^\pm \nu \gamma$ and $K^\pm \to \ell^\pm \nu \gamma$ Form Factors" in the π^\pm Particle Listings for definitions and details.
- [b] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e)+\Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}}=100\%$.
- [c] See the π^\pm Particle Listings for the energy limits used in this measurement; low-energy γ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order 10^{-13} ; see the π^0 Particle Listings.
- [f] See the "Note on the Decay Width $\Gamma(\eta\to\gamma\gamma)$ " in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1451.
- [g] See the "Note on η Decay Parameters" in the η Particle Listings.
- [h] C parity forbids this to occur as a single-photon process.
- [i] See the "Note on scalar mesons" in the $f_0(1370)$ Particle Listings.
- [j] See the "Note on $\rho(770)$ " in the $\rho(770)$ Particle Listings.
- [k] The e^+e^- branching fraction is from $e^+e^- \to \pi^+\pi^-$ experiments only. The $\omega \, \rho$ interference is then due to $\omega \, \rho$ mixing only, and is expected to be small. If $e \, \mu$ universality holds, $\Gamma(\rho^0 \to \mu^+\mu^-) = \Gamma(\rho^0 \to e^+e^-) \times 0.99785$.
- [/] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.
- [m] See the "Note on $a_1(1260)$ " in the $a_1(1260)$ Particle Listings.
- [n] See the "Note on the $f_1(1420)$ " in the $f_1(1420)$ Particle Listings.
- [o] See also the $\omega(1600)$ Particle Listings.
- [p] See the "Note on the $\eta(1440)$ " in the $\eta(1440)$ Particle Listings.
- [q] See the "Note on the $\rho({\rm 1450})$ and the $\rho({\rm 1700})$ " in the $\rho({\rm 1700})$ Particle Listings.
- [r] See the "Note on ${\rm non-}q\,\overline{q}$ mesons" in the Particle Listings (see the index for the page number).
- [s] See also the $\omega(1420)$ Particle Listings.
- [t] See the "Note on $f_J(1710)$ " in the $f_J(1710)$ Particle Listings.
- [u] See the note in the K^{\pm} Particle Listings.
- [v] The definition of the slope parameter g of the $K \to 3\pi$ Dalitz plot is as follows (see also "Note on Dalitz Plot Parameters for $K \to 3\pi$ Decays" in the K^\pm Particle Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \cdots$$

- [w] For more details and definitions of parameters see the Particle Listings.
- [x] See the K^{\pm} Particle Listings for the energy limits used in this measurement
- [y] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [z] Direct-emission branching fraction.
- [aa] Structure-dependent part.
- [bb] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $\tau_{K_5^0}$, and $|m_{K_L^0} m_{K_5^0}|$, as described in the introduction to "Tests of Conservation Laws."

[cc] The CP-violation parameters are defined as follows (see also "Note on CP Violation in $K_S \rightarrow 3\pi$ " and "Note on CP Violation in K_L^0 Decay" in the Particle Listings):

$$\eta_{+-} = |\eta_{+-}| e^{i\phi_{+-}} = \frac{A(K_L^0 \to \pi^+ \pi^-)}{A(K_S^0 \to \pi^+ \pi^-)} = \epsilon + \epsilon'$$

$$\eta_{00} = |\eta_{00}| \mathrm{e}^{i\phi_{00}} = rac{A(K_L^0 o \pi^0 \pi^0)}{A(K_S^0 o \pi^0 \pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) - \Gamma(K_L^0 \to \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) + \Gamma(K_L^0 \to \pi^+ \ell^- \nu)},$$

$${\rm Im}(\eta_{+-0})^2 = \frac{\Gamma(K_S^0 \to \ \pi^+\pi^-\pi^0)^{CP \ {\rm viol.}}}{\Gamma(K_L^0 \to \ \pi^+\pi^-\pi^0)} \ ,$$

$${\rm Im}(\eta_{000})^2 = \frac{\Gamma(K_S^0 \to ~\pi^0 \pi^0 \pi^0)}{\Gamma(K_L^0 \to ~\pi^0 \pi^0 \pi^0)}$$

where for the last two relations *CPT* is assumed valid, *i.e.*, ${\rm Re}(\eta_{+-0})\simeq$ 0 and ${\rm Re}(\eta_{000})\simeq~$ 0.

- [dd] See the K_S^0 Particle Listings for the energy limits used in this measurement.
- [ee] Calculated from K_L^0 semileptonic rates and the K_S^0 lifetime assuming $\Delta S = \Delta Q$.
- [ff] ϵ'/ϵ is derived from $\left|\eta_{00}/\eta_{+-}\right|$ measurements using theoretical input on phases.
- [gg] The value is for the sum of the charge states of particle/antiparticle states indicated.
- [hh] See the K_L^0 Particle Listings for the energy limits used in this measurement.
- $[ii] \ m_{e^+e^-} > 470 \ {
 m MeV}.$
- [jj] Allowed by higher-order electroweak interactions.
- [kk] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.
- [//] See the "Note on $f_0(1370)$ " in the $f_0(1370)$ Particle Listings and in the 1994 edition.
- [mm] See the note in the L(1770) Particle Listings in Reviews of Modern Physics **56** No. 2 Pt. II (1984), p. S200. See also the "Note on $K_2(1770)$ and the $K_2(1820)$ " in the $K_2(1770)$ Particle Listings.
- [nn] See the "Note on $K_2(1770)$ and the $K_2(1820)$ " in the $K_2(1770)$ Particle Listings.
- [oo] This is a weighted average of D^\pm (44%) and D^0 (56%) branching fractions. See " D^+ and $D^0 \to (\eta \, \text{anything}) / (\text{total } D^+ \, \text{and } D^0)$ " under " D^+ Branching Ratios" in the Particle Listings.

- [pp] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ is really an e^+ .
- [qq] ℓ indicates e or μ mode, not sum over modes.
- [rr] The branching fractions for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.
- [ss] The two experiments determining this ratio are in serious disagreement. See the Particle Listings.
- [tt] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.
- [uu] The D_1^0 - D_2^0 limits are inferred from the D^0 - \overline{D}^0 mixing ratio $\Gamma(K^+\pi^-$ or $K^+\pi^-\pi^+\pi^-$ via \overline{D}^0) / $\Gamma(K^-\pi^+$ or $K^-\pi^+\pi^+\pi^-$).
- [vv] This value is calculated from the ratio $\Gamma(K^-\mu^+\nu_\mu)/\Gamma(\mu^+$ anything) in the D^0 Particle Listings.
- [ww] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [xx] For now, we average together measurements of the $\phi\,e^+\nu_e$ and $\phi\,\mu^+\nu_\mu$ branching fractions. This is the average, not the sum.
- [yy] This branching fraction is calculated from appropriate fractions of the next three branching fractions.
- [zz] This value includes only K^+K^- decays of the $f_J(1710)$, because branching fractions of this resonance are not known.
- [aaa] This mode is not a useful test for a ΔC =1 weak neutral current because both quarks must change flavor in this decay.
- $[bbb]\ B^0$ and B^0_s contributions not separated. Limit is on weighted average of the two decay rates.
- [ccc] These values are model dependent. See 'Note on Semileptonic Decays' in the \mathcal{B}^+ Particle Listings.
- [ddd] D^{**} stands for the sum of the $D(1\ ^1P_1),\ D(1\ ^3P_0),\ D(1\ ^3P_1),\ D(1\ ^3P_2),\ D(2\ ^1S_0),$ and $D(2\ ^1S_1)$ resonances.
- [eee] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [fff] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P-wave) states.
- [ggg] Not a pure measurement. See note at head of B_s^0 Decay Modes.
- [hhh] Includes $p\overline{p}\pi^+\pi^-\gamma$ and excludes $p\overline{p}\eta$, $p\overline{p}\omega$, $p\overline{p}\eta'$.
- [iii] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region
- [jjj] Spectroscopic labeling for these states is theoretical, pending experimental information.

See also the table of suggested $q\overline{q}$ quark-model assignments in the Quark Model section.

- Indicates particles that appear in the preceding Meson Summary Table. We do not regard
 the other entries as being established.
- \dagger Indicates that the value of J given is preferred, but needs confirmation.

This short table gives the name, the quantum numbers (where known), and the status of baryons in the Review. Only the baryons with 3-or 4-star status are included in the main Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the short table are not established as baryons. The names with masses are of baryons that decay strongly. See our 1986 edition (Physics Letters 170B) for listings of evidence for Z baryons (KN resonances).

^{****} Existence is certain, and properties are at least fairly well explored.

^{***} Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

^{**} Evidence of existence is only fair.

^{*} Evidence of existence is poor.

N BARYONS (S=0, I=1/2)

 $p, N^+ = uud;$ $n, N^0 = udd$

p

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

Mass $m = 938.27231 \pm 0.00028$ MeV $^{[a]}$ $=\,1.007276470\,\pm\,0.000000012\;u$ $\left|\frac{q_{\overline{p}}}{m_{\overline{p}}}\right|/\left(\frac{q_{p}}{m_{p}}\right) = 1.0000000015 \pm 0.0000000011$ $\left|q_p + q_{\overline{p}}\right|/e \ < \ 2\times 10^{-5}$ $|q_p + q_e|/e < 1.0 \times 10^{-21} [b]$ Magnetic moment $\mu=$ 2.79284739 \pm 0.00000006 μ_N Electric dipole moment $d = (-4 \pm 6) \times 10^{-23}$ ecm Electric polarizability $\overline{\alpha} = (12.1 \pm 0.9) \times 10^{-4} \text{ fm}^3$ $\begin{array}{l} \mbox{Magnetic polarizability } \overline{\beta} = (2.1 \pm 0.9) \times 10^{-4} \ \mbox{fm}^{3} \\ \mbox{Mean life } \tau > 1.6 \times 10^{25} \mbox{ years} \ \ \mbox{(independent of mode)} \\ = > 10^{31} - 5 \times 10^{32} \mbox{ years} \ \mbox{$^{[c]}$} \ \ \mbox{(mode dependent)} \end{array}$

Below, for N decays, p and n distinguish proton and neutron partial lifetimes. See also the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1673) for a short review.

The "partial mean life" limits tabulated here are the limits on $\tau/\mathrm{B}_{\mathrm{J}}$, where au is the total mean life and B_i is the branching fraction for the mode in

BOTTOM (BEAUTY) BARYONS (B=-1)

$$\Lambda_b^0 = u \, d \, b, \, \Xi_b^0 = u \, s \, b, \, \Xi_b^- = d \, s \, b$$

$$I(J^P) = 0(\frac{1}{2}^+)$$

$$I(J^P)$$
 not yet measured; $0(\frac{1}{2}^+)$ is the quark model prediction. Mass $m=5641\pm50$ MeV Mean life $\tau=(1.14\pm0.08)\times10^{-12}$ s $c\tau=342~\mu{\rm m}$

These branching fractions are actually an average over weakly decaying b-b-b-a-y-o-s weighted by their production rates in Z decay (or high-energy $p\overline{p}$), branching ratios, and detection efficiencies. They scale with the LEP Λ_b production fraction $B(b\to\Lambda_b)$ and are evaluated for our value $B(b\to\Lambda_b)=(13.2\pm4.1)\%.$

The branching fractions $\mathrm{B}(\Lambda_b^0\to\Lambda\ell^-\overline{\nu}_\ell$ anything) and $\mathrm{B}(\Lambda_b^0\to\Lambda_c^+\ell^-\overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with $\mathrm{B}(b\to\Lambda_b)$ were used to determine $\mathrm{B}(b\to\Lambda_b)$, as described in the note "Production and Decay of b-Flavored Hadrons."

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters. The Particle Listings also give, where available, pole parameters. See, in particular, the *Note on N and \(\Delta \) Resonances.*

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The Note on N and Δ Resonances and the Note on Λ and Σ Resonances in the Particle Listings review the partial-wave analyses.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p. A dagger ("†") in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

- [a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u = 931.49432 \pm 0.00028 MeV, is less well known than are the masses in u.
- [b] The limit is from neutrality-of-matter experiments; it assumes $q_n=q_p+q_e$. See also the charge of the neutron.
- [c] The first limit is geochemical and independent of decay mode. The second entry, a range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray \bar{p} 's is $\tau_{\bar{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\bar{p}}/B(\bar{p} \to e^-\gamma) > 1848$ yr.
- [d] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The second limit here is from reactor experiments with free neutrons.
- [e] The parameters g_A , g_V , and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V+g_A\gamma_5)+i(g_{WM}/m_{B_i})\;\sigma_{\lambda\nu}\;q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V=|g_A/g_V|e^{i\phi_{AV}}$. See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.
- [f] Time-reversal invariance requires this to be 0° or 180° .
- [g] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-lpha^2} \cos \phi$$
 , $an \Delta = -rac{1}{lpha} \, \sqrt{1-lpha^2} \sin \phi$.

See the "Note on Baryon Decay Parameters" in the neutron Particle Listings

- [h] See the Particle Listings for the pion momentum range used in this measurement.
- [i] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.
- [i] A theoretical value using QED.
- $[\emph{k}]$ This branching fraction includes all the decay modes of the final-state resonance.
- [I] ℓ indicates e or μ mode, not sum over modes.
- [m] The value is for the sum of the charge states of particle/antiparticle states indicated
- [n] Not a pure measurement. See note at head of Λ_b^0 Decay Modes.

MONOPOLES, SUPERSYMMETRY, COMPOSITENESS, etc., SEARCHES FOR

Magnetic Monopole Searches

Isolated candidate events have not been confirmed. Most experiments obtain negative results.

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model. Assumptions include: 1) $\widetilde{\chi}_1^0$ (or $\widetilde{\gamma}$) is lightest supersymmetric particle; 2) R-parity is conserved; 3) $m_{\widetilde{I}_L} = m_{\widetilde{I}_R}$, and all scalar quarks (except \widetilde{t}_L and \widetilde{t}_R) are degenerate in mass.

See the Particle Listings for a Note giving details of supersymmetry.

 $\widetilde{\nu}$ — scalar neutrino (sneutrino)

Mass m > 37.1 GeV, CL = 95% [one flavor] Mass m > 41.8 GeV, CL = 95% [three degenerate flavors]

 \tilde{e} — scalar electron (selectron)

$$\begin{array}{lll} \text{Mass } m > \ 65 \text{ GeV, CL} = 95\% & & [\text{if } m_{\widetilde{\gamma}} = 0] \\ \text{Mass } m > \ 50 \text{ GeV, CL} = 95\% & & [\text{if } m_{\widetilde{\gamma}} < 5 \text{ GeV}] \\ \text{Mass } m > \ 45 \text{ GeV, CL} = 95\% & & [\text{if } m_{\widetilde{\chi}_1^0} < 41 \text{ GeV}] \end{array}$$

 $\widetilde{\mu}$ — scalar muon (smuon)

Mass
$$m>$$
 45 GeV, CL $=$ 95% [if $m_{\widetilde{\chi}^0_1}<$ 41 GeV]

 $\widetilde{ au}$ — scalar tau (stau)

Mass
$$m>$$
 45 GeV, CL $=$ 95% [if $m_{\widetilde{\chi}_1^0}<$ 38 GeV]

 \tilde{q} — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}^0_1} \approx m_{\widetilde{g}}/6$.

$$\begin{array}{ll} \text{Mass } m > \ 176 \ \text{GeV, CL} = 95\% & [\text{any } m_{\widetilde{g}} < 300 \ \text{GeV,} \\ \mu = -250 \ \text{GeV, } \tan\beta = 2] \\ \text{Mass } m > \ 224 \ \text{GeV, CL} = 95\% & [m_{\widetilde{g}} \leq m_{\widetilde{d}}, \\ \mu = -400 \ \text{GeV, } \tan\beta = 4] \end{array}$$

 \widetilde{g} — gluino

There is some controversy about a low-mass window (1 $\lesssim m_{\widetilde{g}} \lesssim$ 4 GeV). Several experiments cast doubt on the existence of this window.

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}_1^0} \approx m_{\widetilde{g}}/6$.

$$\begin{array}{ll} \text{Mass } m > \ 154 \ \text{GeV}, \ \text{CL} = 95\% & [m_{\widetilde{g}} \leq m_{\widetilde{q}}, \ \mu = -400 \ \text{GeV}, \\ \tan\beta = 4] \\ \text{Mass } m > \ 212 \ \text{GeV}, \ \text{CL} = 95\% & [m_{\widetilde{g}} \geq m_{\widetilde{q}}, \ \mu = -250 \ \text{GeV}, \\ \tan\beta = 2] \end{array}$$

Quark and Lepton Compositeness, Searches for

Scale Limits A for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \overline{\psi}_L \gamma_\mu \psi_L \overline{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^{\pm}$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$$\begin{array}{lll} \Lambda_{LL}^+(e\,e\,e\,e) &> 1.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^-(e\,e\,e\,e) &> 3.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(e\,e\,\mu\,\mu) &> 2.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^-(e\,e\,\mu\,\mu) &> 1.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(e\,e\,\tau\,\tau) &> 1.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^-(e\,e\,\tau\,\tau) &> 2.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(e\,e\,\tau\,\tau) &> 2.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(\ell\,\ell\ell\ell) &> 3.5 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(\ell\ell\ell\ell) &> 2.8 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(\ell\ell\ell\ell) &> 2.3 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(e\,e\,q\,q) &> 2.2 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(\mu\mu\,q\,q) &> 1.4 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(\mu\mu\,q\,q) &> 1.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LR}^+(\nu_\mu\nu_e\mu\,e) &> 3.1 \; {\rm TeV}, \; {\rm CL} = 90\% \\ \Lambda_{LL}^+(q\,q\,q\,q) &> 1.4 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^+(q\,q\,q\,q) &> 1.4 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \end{array}$$

Recent CDF measurements of the inclusive jet cross section in $p\overline{p}$ collisions could be interpreted as tentative evidence for a four-quark contact interaction with Λ_{LL}^{\pm} ($q\,q\,q\,q\rangle\sim1.6$ TeV. However, CDF notes that uncertainty in the parton distribution functions, higher-order QCD corrections, and detector calibration may possibly account for the effect.

Excited Leptons

The limits from $\ell^{*+}\ell^{*-}$ do not depend on λ (where λ is the $\ell\ell^*$ transition coupling). The λ -dependent limits assume chiral coupling, except for the third limit for e^* which is for nonchiral coupling. For chiral coupling, this limit corresponds to $\lambda_\gamma = \sqrt{2}$.

 $e^{*\pm}$ — excited electron

```
\begin{array}{lll} \mbox{Mass } m > & 46.1 \mbox{ GeV, CL} = 95\% & (\mbox{from } e^{*+}e^{*-}) \\ \mbox{Mass } m > & 91 \mbox{ GeV, CL} = 95\% & (\mbox{if } \lambda_Z > 1) \\ \mbox{Mass } m > & 146 \mbox{ GeV, CL} = 95\% & (\mbox{if } \lambda_{\gamma} = 1) \end{array}
```

 $\mu^{*\pm}$ — excited muon

Mass
$$m > 46.1$$
 GeV, CL = 95% (from $\mu^{*+}\mu^{*-}$)
Mass $m > 91$ GeV, CL = 95% (if $\lambda_Z > 1$)

 $\tau^{*\pm}$ — excited tau

Mass
$$m>$$
 46.0 GeV, CL = 95% (from $\tau^{*+}\tau^{*-}$)
Mass $m>$ 90 GeV, CL = 95% (if $\lambda_Z>0.18$)

 $\nu^* - \text{excited neutrino}$

$$\begin{array}{lll} \text{Mass } m > \ \, \text{47 GeV, CL} = 95\% & \text{(from } \nu^* \overline{\nu}^*) \\ \text{Mass } m > \ \, \text{91 GeV, CL} = 95\% & \text{(if } \lambda_Z \ > \ 1) \end{array}$$

 q^* — excited quark

Color Octet Neutrinos (ν_8)

Mass
$$m>~110$$
 GeV, CL = 90% ($\nu_8 \rightarrow ~\nu\,g$)

TESTS OF CONSERVATION LAWS

Revised by L. Wolfenstein and T.G. Trippe, June 1996.

In keeping with the current interest in tests of conservation laws, we collect together a Table of experimental limits on all weak and electromagnetic decays, mass differences, and moments, and on a few reactions, whose observation would violate conservation laws. The Table is given only in the full Review of Particle Physics, not in the Particle Physics Booklet. For the benefit of Booklet readers, we include the best limits from the Table in the following text. The Table is in two parts: "Discrete Space-Time Symmetries," i.e., C, P, T, CP, and CPT; and "Number Conservation Laws," i.e., lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Particle Listings in the Review. A discussion of these tests follows.

CPT INVARIANCE

General principles of relativistic field theory require invariance under the combined transformation CPT. The simplest tests of CPT invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between K^0 and \overline{K}^0 . Any such difference contributes to the CP-violating parameter ϵ . Assuming CPT invariance, ϕ_{ϵ} , the phase of ϵ should be very close to 44°. (See the "Note on CP Violation in K^0_L Decay" in the Particle Listings.) In contrast, if the entire source of CP violation in K^0_L decays were a $K^0-\overline{K}^0$ mass difference, ϕ_{ϵ} would be $44^\circ+90^\circ$. It is possible to deduce that [1]

$$m_{\overline{K}^0} - m_{K^0} \approx \frac{2(m_{K^0_L} - m_{K^0_S}) \left| \eta \right| \left(\frac{2}{3} \phi_{+-} + \frac{1}{3} \phi_{00} - \phi_\epsilon \right)}{\sin \phi_\epsilon} \; . \label{eq:mk0}$$

Using our best values of the CP-violation parameters, we get $|(m_{\overline{K}^0} - m_{K^0})/m_{K^0}| \leq 9 \times 10^{-19}$ (CL = 90%). Limits can also be placed on specific CPT-violating decay amplitudes. Given the small value of $(1-|\eta_{00}/\eta_{+-}|)$, the value of $\phi_{00}-\phi_{+-}$ provides a measure of CPT violation in $K_L^0 \to 2\pi$ decay. Results from CERN [1] and Fermilab [2] indicate no CPT-violating effect.

CP AND T INVARIANCE

Given CPT invariance, CP violation and T violation are equivalent. So far the only evidence for CP or T violation comes from the measurements of η_{+-} , η_{00} , and the semileptonic decay charge asymmetry for $K_L,\ e.g.,\ |\eta_{+-}|=|A(K_L^0 o\pi^+\pi^-)/A(K_S^0$ $\to \pi^+\pi^-)|=(2.285\pm 0.019) imes 10^{-3} ext{ and } [\Gamma(K_L^0 \to \pi^-e^+
u)]$ $\Gamma(K_L^0 \to \pi^+ e^- \overline{\nu})]/[\text{sum}] = (0.333 \pm 0.014)\%$. Other searches for \overline{CP} or T violation divide into (a) those that involve weak interactions or parity violation, and (b) those that involve processes otherwise allowed by the strong or electromagnetic interactions. In class (a) the most sensitive are probably the searches for an electric dipole moment of the neutron, measured to be $< 1.1 \times 10^{-25}$ e cm (95% CL), and the electron $(-0.3 \pm 0.8) \times 10^{-26}$ e cm. A nonzero value requires both P and T violation. Class (b) includes the search for C violation in η decay, believed to be an electromagnetic process, e.g., as measured by $\Gamma(\eta \to \mu^+ \mu^- \pi^0)/\Gamma(\eta \to \text{all}) < 5 \times 10^{-6}$, and searches for T violation in a number of nuclear and electromagnetic reactions.

CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number L_e , muon number L_{μ} , and tau number L_{τ} . Searches for violations are of the following types:

- a) $\Delta L=2$ for one type of lepton. The best limit comes from the search for neutrinoless double beta decay $(Z,A) \rightarrow (Z+2,A)+e^-+e^-$. The best laboratory limit is $t_{1/2}>5.6\times 10^{24}$ yr (CL=90%) for ⁷⁶Ge.
- b) Conversion of one lepton type to another. For purely leptonic processes, the best limits are on $\mu \to e \gamma$ and $\mu \to 3e$, measured as $\Gamma(\mu \to e \gamma)/\Gamma(\mu \to \text{all}) < 5 \times 10^{-11}$ and $\Gamma(\mu \to 3e)/\Gamma(\mu \to \text{all}) < 1.0 \times 10^{-12}$. For semileptonic processes, the best limit comes from the coherent conversion process in a muonic atom, $\mu^- + (Z,A) \to e^- + (Z,A)$, measured as $\Gamma(\mu^-\text{Ti} \to e^-\text{Ti})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 4 \times 10^{-12}$. Of special interest is the case in which the hadronic flavor also changes, as in $K_L \to e\mu$ and $K^+ \to \pi^+e^-\mu^+$, measured as $\Gamma(K_L \to e\mu)/\Gamma(K_L \to \text{all}) < 3.3 \times 10^{-11}$ and $\Gamma(K^+ \to \pi^+e^-\mu^+)/\Gamma(K^+ \to \text{all}) < 2.1 \times 10^{-10}$. Limits on the conversion of τ into e or μ are found in τ decay and are much less stringent than those for $\mu \to e$ conversion, e.g., $\Gamma(\tau \to \mu\gamma)/\Gamma(\tau \to \text{all}) < 4.2 \times 10^{-6}$ and $\Gamma(\tau \to e\gamma)/\Gamma(\tau \to \text{all}) < 1.1 \times 10^{-4}$.
- c) Conversion of one type of lepton into another type of antilepton. The case most studied is $\mu^- + (Z,A) \rightarrow e^+ + (Z-2,A)$, the strongest limit being $\Gamma(\mu^- {\rm Ti} \rightarrow e^+ {\rm Ca})/\Gamma(\mu^- {\rm Ti} \rightarrow {\rm all}) < 9 \times 10^{-11}$.
- d) Relation to neutrino mass. If neutrinos have mass, then it is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo quark mixing. However, in this case lepton-number-violating processes such as $\mu \to e\gamma$ are expected to have extremely small probability. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental searches. For example, searches for $\overline{\nu}_e$ disappearance, which we label as $\overline{\nu}_e \not \to \overline{\nu}_e$, give measured limits $\Delta(m^2) < 0.0075 \text{ eV}^2 \text{ for } \sin^2(2\theta) = 1, \text{ and } \sin^2(2\theta) < 0.02 \text{ for }$ large $\Delta(m^2)$, where θ is the neutrino mixing angle. Searches for $\nu_{\mu} \rightarrow \nu_{e} \text{ limit } \sin^{2}(2\theta) < 0.0025 \text{ for large } \Delta(m^{2}).$ For larger neutrino masses (>> 1 keV), lepton-number violation is searched for by looking for anomalous decays such as $\pi \to e\nu_x$, where ν_x is a massive neutrino. If the $\Delta L=2$ type of violation occurs, it is expected that neutrinos will have a nonzero mass of the Majorana type.

CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, i.e. the conversion of a quark of one flavor (d,u,s,c,b,t) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section "Cabibbo-Kobayashi-Maskawa Mixing Matrix"). The way in which these conservation laws are violated is tested as follows:

- a) $\Delta S = \Delta Q$ rule. In the semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as $\Gamma(\Sigma^+ \to n e^+ \nu)/\Gamma(\Sigma^+ \to \text{all}) < 5 \times 10^{-6}$, and from a detailed analysis of $K_L \to \pi e \nu$, which yields the parameter x, measured to be $(\text{Re}\,x,\,\text{Im}\,x) = (0.006 \pm 0.018,\,-0.003 \pm 0.026)$. Corresponding rules are $\Delta C = \Delta Q$ and $\Delta B = \Delta Q$.
- b) Change of flavor by two units. In the Standard Model this occurs only in second-order weak interactions. The classic example is $\Delta S=2$ via $K^0-\overline{K}^0$ mixing, which is directly measured by $m(K_S)-m(K_L)=(3.491\pm0.009)\times10^{-12}$ MeV. There

Tests of Conservation Laws

is now evidence for $B^0-\overline{B}^0$ mixing $(\Delta B=2),$ with the corresponding mass difference between the eigenstates $(m_{B^0_{\rm H}}-m_{B^0_{\rm L}})=(0.73\pm0.05)\Gamma_{B^0}=(3.12\pm0.21)\times10^{-10}$ MeV, and for $B^0_s-\overline{B}^0_s$ mixing, with $(m_{B^0_{sH}}-m_{B^0_{sL}})>9.5\Gamma_{B^0_s}$ or $>4\times10^{-9}$ MeV. No evidence exists for $D^0-\overline{D}^0$ mixing, which is expected to be much smaller in the Standard Model.

c) Flavor-changing neutral currents. In the Standard Model the neutral-current interactions do not change flavor. The low rate $\Gamma(K_L \to \mu^+ \mu^-)/\Gamma(K_L \to {\rm all}) = (7.2 \pm 0.5) \times 10^{-9}~{\rm puts}$ limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from a limit on $K^+ \to \pi^+ \nu \overline{\nu}$. which occurs in the Standard Model only as a second-order weak process with a branching fraction of $(1 \text{ to } 8) \times 10^{-10}$. The current limit is $\Gamma(K^+ \to \pi^+ \nu \overline{\nu})/\Gamma(K^+ \to \text{all}) < 2.4 \times 10^{-9}$. Limits for charm-changing or bottom-changing neutral currents are much less stringent: $\Gamma(D^0 \to \mu^+ \mu^-)/\Gamma(D^0 \to \text{all}) < 8 \times 10^{-6}$ and $\Gamma(B^0 \to \mu^+ \mu^-)/\Gamma(B^0 \to \text{all}) < 5.9 \times 10^{-6}$. One cannot isolate flavor-changing neutral current (FCNC) effects in non leptonic decays. For example, the FCNC transition $s \to d + (\overline{u} + u)$ is equivalent to the charged-current transition $s \to u + (\overline{u} + d)$. Tests for FCNC are therefore limited to hadron decays into lepton pairs. Such decays are expected only in second-order in the electroweak coupling in the Standard Model.

Limits are given at the 90% confidence level, while errors are given as ± 1 standard deviation.

$\Delta B = 1$ WEAK NEUTRAL CURRENT FORBIDDEN

Allowed by higher-order electroweak interactions.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

- [a] C parity forbids this to occur as a single-photon process.
- [b] Time-reversal invariance requires this to be 0° or 180°.
- [c] Allowed by higher-order electroweak interactions.
- [d] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.
- $[e]\,\epsilon'/\epsilon$ is derived from $\left|\eta_{00}/\eta_{+-}\right|$ measurements using theoretical input on phases.
- [f] Neglecting photon channels. See, e.g., A. Pais and S.B. Treiman, Phys. Rev. D12, 2744 (1975).
- [g] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $\tau_{K^0_S}$, and $|m_{K^0_L} m_{K^0_C}|$, as described in the introduction to "Tests of Conservation Laws."
- [h] The value is for the sum of the charge states of particle/antiparticle states indicated
- [i] A test of additive vs. multiplicative lepton family number conservation.
- $[j] \Delta(m^2) = 100 \text{ eV}^2.$
- [k] 190 eV² $< \Delta(m^2) < 320 \text{ eV}^2$.
- [/] Derived from an analysis of neutrino-oscillation experiments.
- [m] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The second limit here is from reactor experiments with free neutrons.
- [n] This is the best "electron disappearance" limit. The best limit for the mode $e^-\to\nu\gamma$ is $>2.35\times10^{25}$ yr (CL=68%).
- [o] The D_1^0 - D_2^0 limits are inferred from the D^0 - \overline{D}^0 mixing ratio [$\Gamma(K^+\pi^-$ or $K^+\pi^-\pi^+\pi^-$ via \overline{D}^0)] / $\Gamma(K^-\pi^+$ or $K^-\pi^+\pi^+\pi^-$).
- [p] See the \mathcal{K}^0_L Particle Listings for the energy limits used in this measurement.
- $[q] m_{e^+e^-} > 470 \text{ MeV}.$

1. PHYSICAL CONSTANTS

Table 1.1. Reviewed 1995 by B.N. Taylor, NIST. Based mainly on the "1986 Adjustment of the Fundamental Physical Constants" by E.R. Cohen and B.N. Taylor, Rev. Mod. Phys. 59, 1121 (1987). The last group of constants (beginning with the Fermi coupling constant) comes from the Particle Data Group. The figures in parentheses after the values give the 1-standard-deviation uncertainties in the last digits; the corresponding uncertainties in parts per million (ppm) are given in the last column. This set of constants (aside from the last group) is recommended for international use by CODATA (the Committee on Data for Science and Technology).

Since the 1986 adjustment, new experiments have yielded improved values for a number of constants, including the Rydberg constant R_{∞} , the Planck constant h, the fine-structure constant α , and the molar gas constant R, and hence also for constants directly derived from these, such as the Boltzmann constant k and Stefan-Boltzmann constant σ . The new results and their impact on the 1986 recommended values are discussed extensively in "Recommended Values of the Fundamental Physical Constants: A Status Report," B.N. Taylor and E.R. Cohen, J. Res. Natl. Inst. Stand. Technol. 95, 497 (1990); see also E.R. Cohen and B.N. Taylor, "The Fundamental Physical Constants," Phys. Today, August 1995 Part 2, BG9. In general, the new results give uncertainties for the affected constants that are 5 to 7 times smaller than the 1986 uncertainties, but the changes in the values themselves are smaller than twice the 1986 uncertainties. Because the output values of a least-squares adjustment are correlated, the new results cannot readily be incorporated with the 1986 values. Until the next complete adjustment of the constants, the 1986 CODATA set, given (in part) below, remains the set of choice.

Quantity	Symbol, equation	Value U1	ncert. (ppm)

^{*} The meter is the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second.

 $^{^\}dagger$ At $Q^2=0.$ At $Q^2\approx m_W^2$ the value is approximately 1/128.

[‡] See discussion in Sec. 10 "Standard Model of electroweak interactions."

2. ASTROPHYSICAL CONSTANTS

Table 2.1. Written and revised with the help of K.R. Lang, K.A. Olive, J. Primack, S. Rudaz, E.M. Standish, Jr., and M.S. Turner. The figures in parentheses after some values give the 1-standard deviation uncertainties in the last digit(s). While every effort has been made to obtain the most accurate current values of the listed quantities, the table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference.

- 4. JPL Planetary Ephemerides, E. Myles Standish, Jr., private communication (1989).
- 5. 1 AU divided by $\pi/648000$; quoted error is from the JPL Planetary Ephemerides value of the AU [4].
- 6. Heliocentric gravitational constant from Ref. 3 times $2/c^2$. The given 9-place accuracy appears to be consistent with uncertainties in actually defining the earth's orbital parameters.
- 7. Obtained from the heliocentric gravitational constant [3] and G_N [2]. The error is the 128 ppm standard deviation quoted for G_N .
- It is surprisingly difficult to find a definitive value for this important constant. In all cases, the solar luminosity is calculated as $4\pi \times (1 \text{ AU})^2$ times the solar constant (or total solar irradiance, TSI). The luminosity given is reduced from TSI = 1367.51 ± 0.01 W m⁻², obtained from SMM/ACRIMI spacecraft measurements during the interval 2/80-6/89 [25]. While the time constant for energy production by the sun is very long, radiation from the surface might be modulated or otherwise modified by sunspots; this has apparently not been taken into account. Accordingly, we quote 4-place accuracy. We do not know the actual error, but suppose it might be 5 or 10 in the last place. Sackmann et al. [26] use $TSI = 1370 \pm 2 \text{ W m}^{-2}$, but conclude that the solar luminosity $(L_{\odot} = 3.853 \times 10^{26} \text{ J s}^{-1})$ has an uncertainty of 1.5%. Their value is based on three 1977-83 papers, and they comment that the error is based on scatter among the reported values, which is substantially in excess of that expected from the individual quoted errors. The conclusion of the 1971 review by Thekaekara and Drummond [27] $(1353 \pm 1\% \text{ W m}^{-2})$ is often quoted [28], and a luminosity based on this value was tabulated in the last two editions of this Review. The conversion to luminosity is not given in the Thekaekara and Drummond paper, and we cannot exactly reproduce the solar luminosity given in Ref. 28. Finally, a value based on the 1954 spectral curve due to Johnson [29] (1395 \pm 1% W m⁻², or $L_{\odot} = 3.92 \times 10^{26} \text{ J s}^{-1}$) has been used widely, and may be the basis for higher value of the solar luminosity and corresponding lower value of the solar absolute bolometric magnitude (4.72) still common in the literature [10].
- 9. Obtained from the geocentric gravitational constant [3] and G_N [2]. The error is the 128 ppm standard deviation quoted for G_N .

4. PERIODIC TABLE OF THE ELEMENTS

longest-lived isotope of that element—no stable isotope exists. For elements 110–112, the atomic numbers of known isotopes are given. However, although Th, Pa, and U have no stable isotopes, they do have characteristic terrestrial compositions, and meaningful weighted masses can be given. Adapted from "Atomic Weights of the Elements 1993," Pure and Applied Chemistry 66, 2423 (1994), and G. Audi and A.H. Wapstra, "The 1993 Mass Evaluation," Nucl. Phys. A565, 1 (1993). The names given below for elements 104 to 109 have been adopted by the American Chemical Society. The nomenclature committee of the International Union of Pure and Applied Chemistry in 1994 recommended different names for elements 104 to 108, but in the subsequent uproar has postponed a final decision until 1997. Table 4.1. Revised 1995. The atomic number (top left) is the number of protons in the nucleus. The atomic mass (bottom) is weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of the carbon-12 isotope, defined to be exactly 12 unified atomic mass units (u). Errors range from 1 to 9 in the last digit quoted. Relative isotopic abundances often vary considerably, both in natural and commercial samples. A number in parentheses is the mass of the

5. ELECTRONIC STRUCTURE OF THE ELEMENTS

Table 5.1. Reviewed 1995 by W.C. Martin, NIST. The electronic configurations and ionization energies here are taken from "Atomic Spectroscopy," W.C. Martin and W.L. Wiese, in *Atomic, Molecular, and Optical Physics Reference Book*, G.W.F. Drake, ed., Amer. Inst. Phys., 1995. The electron configuration for, say, iron indicates an argon electronic core (see argon) plus six 3d electrons and two 4s electrons. The ionization energy is the least energy necessary to remove to infinity one electron from an atom of the element.

٠	Elen	nent	Electron configuration $(3d^5 = \text{five } 3d \text{ electron})$			Ground state ${}^{2S+1}L_J$	Ionization energy (eV)

6. ATOMIC AND NUCLEAR PROPERTIES OF MATERIALS

Table 6.1. Table revised May 1996. Gases are evaluated at 20°C and 1 atm (in parentheses) or at STP [square brackets]. Densities and refractive indices without parentheses or brackets are for solids or liquids, or are for cryogenic liquids at the indicated boiling point (BP) at 1 atm. Refractive indices are evaluated at the sodium D line.

Material	Z	A	$egin{array}{c} ext{Nuclear}^a \ ext{total} \ ext{cross} \ ext{section} \end{array}$	Nuclear ^b inelastic cross section		Nuclear c interaction length λ_I	$\left. \frac{dE/dx _{\min}^{ d}}{\left\{ \frac{\text{MeV}}{\text{g/cm}^2} \right\}} \right.$		tion length e X_0 A^2 {cm}	$\{g/cm^2\}$	Refractive index n $(n-1)\times 10^6$ for gas)

 σ_T , σ_I , λ_T , and λ_I are energy dependent. Values quoted apply to high energy range given in footnote a or b, where energy dependence is weak

- a. $\sigma_{\rm total}$ at 80–240 GeV for neutrons ($\approx \sigma$ for protons) from Murthy et al., Nucl. Phys. **B92**, 269 (1975). This scales approximately as $A^{0.77}$.
- b. $\sigma_{\text{inelastic}} = \sigma_{\text{total}} \sigma_{\text{elastic}} \sigma_{\text{quasielastic}}$; for neutrons at 60–375 GeV from Roberts et al., Nucl. Phys. **B159**, 56 (1979). For protons and other particles, see Carroll et al., Phys. Lett. **80B**, 319 (1979); note that $\sigma_I(p) \approx \sigma_I(n)$. σ_I scales approximately as $A^{0.71}$.
- c. Mean free path between collisions (λ_I) or inelastic interactions (λ_I) , calculated from $\lambda = A/(N \times \sigma)$, where N is Avogadro's number.
- d. For minimum-ionizing heavy particles (calculated for pions; results are very slightly different for other particles). Minimum dE/dx calculated in 1994, using density effect correction coefficients from R. M. Sternheimer, M. J. Berger, and S. M. Seltzer, Atomic Data and Nuclear Data Tables 30, 261–271 (1984). For electrons and positrons see S.M. Seltzer and M.J. Berger, Int. J. Appl. Radiat. 35, 665–676 (1984). Ionization energy loss is discussed in Sec. 22.
- e. From Y.S. Tsai, Rev. Mod. Phys. 46, 815 (1974); X₀ data for all elements up to uranium are given. Corrections for molecular binding applied for H₂ and D₂.
- f. Density effect constants evaluated for $\rho = 0.0600 \text{ g/cm}^3$ (H₂ bubble chamber?).
- g. For pure graphite; industrial graphite density may vary 2.1-2.3 g/cm³.
- h. Standard shielding blocks, typical composition O_2 52%, Si 32.5%, Ca 6%, Na 1.5%, Fe 2%, Al 4%, plus reinforcing iron bars. The attenuation length, $\ell=115\pm5$ g/cm², is also valid for earth (typical $\rho=2.15$), from CERN-LRL-RHEL Shielding exp., UCRL-17841 (1968).
- i. Main components: $80\% \text{ SiO}_2 + 12\% \text{ B}_2\text{O}_3 + 5\% \text{ Na}_2\text{O}$.
- j. Calculated using Sternheimer's density effect parameterization for $\rho = 2.32$ g cm⁻³. Actual value may be slightly lower.
- k. For typical fused quartz. The specific gravity of crystalline quartz is 2.64.
- ℓ. Solid ethane density at −60°C; gaseous refractive index at 0°C, 546 mm pressure.
- m. $n(SiO_2) + 2n(H_2O)$ used in Čerenkov counters, $\rho = \text{density in g/cm}^3$. From M. Cantin et al., Nucl. Instr. and Meth. 118, 177 (1974).
- n. G10-plate, typical 60% SiO₂ and 40% epoxy.

7. ELECTROMAGNETIC RELATIONS

Quantity	Gaussian CGS	SI
Conversion factors:		
Charge:	$2.997\ 924\ 58 \times 10^9\ \mathrm{esu}$	= 1 C = 1 A s
Potential:	(1/299.792 458) statvolt (ergs/esu)	$= 1 \text{ V} = 1 \text{ J C}^{-1}$
Magnetic field:	$10^4 \text{ gauss} = 10^4 \text{ dyne/esu}$	$= 1 \text{ T} = 1 \text{ N A}^{-1} \text{m}^{-1}$
Lorentz force:	$\mathbf{F} = q\left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B}\right)$	$\mathbf{F} = q\left(\mathbf{E} + \mathbf{v} \times \mathbf{B}\right)$
Maxwell equations:	$\nabla \cdot \mathbf{D} = 4\pi \rho$	$\nabla \cdot \mathbf{D} = \rho$
	$\nabla \times \mathbf{H} - \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} = \frac{4\pi}{c} \mathbf{J}$	$\nabla \times \mathbf{H} - \frac{\partial \mathbf{D}}{\partial t} = \mathbf{J}$
	$\nabla \cdot \mathbf{B} = 0$	$\nabla \cdot \mathbf{B} = 0$
	$\nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0$	$\nabla \times \mathbf{E} + \frac{\partial \mathbf{B}}{\partial t} = 0$
Constitutive relations:	$\mathbf{D} = \mathbf{E} + 4\pi \mathbf{P}, \mathbf{H} = \mathbf{B} - 4\pi \mathbf{M}$	$\mathbf{D} = \epsilon_0 \mathbf{E} + \mathbf{P}, \mathbf{H} = \mathbf{B}/\mu_0 - \mathbf{M}$
Linear media:	$\mathbf{D} = \epsilon \mathbf{E}, \mathbf{H} = \mathbf{B}/\mu$	$\mathbf{D} = \epsilon \mathbf{E}, \mathbf{H} = \mathbf{B}/\mu$
Permitivity of free space:	1	$\epsilon_0 = 8.854 \ 187 \dots \times 10^{-12} \ \mathrm{F \ m^{-1}}$
Permeability of free space:	1	$\mu_0 = 4\pi \times 10^{-7} \text{ N A}^{-2}$
Fields from potentials:	$\mathbf{E} = -\nabla V - \frac{1}{c} \frac{\partial \mathbf{A}}{\partial t}$	$\mathbf{E} = -\nabla V - \frac{\partial \mathbf{A}}{\partial t}$
	$\mathbf{B} = \mathbf{\nabla} \times \mathbf{A}$	$\mathbf{B} = \mathbf{\nabla} \times \mathbf{A}$
Static potentials: (coulomb gauge)	$V = \sum_{\text{charges}} \frac{q_i}{r_i} = \int \frac{\rho(\mathbf{r}')}{ \mathbf{r} - \mathbf{r}' } d^3x'$	$V = \frac{1}{4\pi\epsilon_0} \sum_{\text{charges}} \frac{q_i}{r_i} = \frac{1}{4\pi\epsilon_0} \int \frac{\rho(\mathbf{r}')}{ \mathbf{r} - \mathbf{r}' } d^3x'$
	$\mathbf{A} = \frac{1}{c} \sum_{\text{currents}} \frac{\mathbf{I}_i}{r_i} = \frac{1}{c} \int \frac{\mathbf{J}(\mathbf{r}')}{ \mathbf{r} - \mathbf{r}' } d^3 x'$	$\mathbf{A} = \frac{\mu_0}{4\pi} \sum_{\text{currents}} \frac{\mathbf{I}_i}{r_i} = \frac{\mu_0}{4\pi} \int \frac{\mathbf{J}(\mathbf{r}')}{ \mathbf{r} - \mathbf{r}' } d^3x'$
Relativistic transformations:	$\mathbf{E}_{\parallel}' = \mathbf{E}_{\parallel}$	$\mathbf{E}_{\parallel}' = \mathbf{E}_{\parallel}$
(v is the velocity of the primed frame as seen	$\mathbf{E}'_{\perp} = \gamma(\mathbf{E}_{\perp} + \frac{1}{c}\mathbf{v} \times \mathbf{B})$	$\mathbf{E}'_{\perp} = \gamma (\mathbf{E}_{\perp} + \mathbf{v} \times \mathbf{B})$
in the unprimed frame)	$\mathbf{B}_{\parallel}' = \mathbf{B}_{\parallel}$	$\mathbf{B}'_{\parallel} = \mathbf{B}_{\parallel}$
	$\mathbf{B}'_{\perp} = \gamma(\mathbf{B}_{\perp} - \frac{1}{c}\mathbf{v} \times \mathbf{E})$	$\mathbf{B}'_{\perp} = \gamma (\mathbf{B}_{\perp} - \frac{1}{c^2} \mathbf{v} \times \mathbf{E})$
$\frac{1}{4\pi\epsilon_0} = c^2 \times 10^{-7} \text{ N A}^{-2} = 8.9$	$87.55 \times 10^9 \text{ m F}^{-1}$; $\frac{\mu_0}{4\pi} = 10^{-7} \text{ N A}$	$c = \frac{1}{\sqrt{\mu_0 \epsilon_0}} = 2.99792458 \times 10^8 \text{ m s}^{-1}$

7.1. Impedances (SI units)

 ρ = resistivity at room temperature in $10^{-8} \Omega$ m:

For alternating currents, instantaneous current I, voltage V, angular frequency $\omega\colon$

$$V = V_0 e^{j\omega t} = ZI . (7.1)$$

Impedance of self-inductance L: $Z = j\omega L$.

Impedance of capacitance C: $Z = 1/j\omega C$.

Impedance of free space: $Z = \sqrt{\mu_0/\epsilon_0} = 376.7 \ \Omega$.

High-frequency surface impedance of a good conductor:

$$Z = \frac{(1+j) \rho}{\delta}$$
, where $\delta = \text{skin depth}$; (7.2)

$$\delta = \sqrt{\frac{\rho}{\pi \nu \mu}} \approx \frac{6.6 \text{ cm}}{\sqrt{\nu (\text{Hz})}} \text{ for Cu}.$$
 (7.3)

7.2. Capacitance \widehat{C} and inductance \widehat{L} per unit length (SI units) [negligible skin depth]

Flat rectangular plates of width w, separated by $d \ll w$ with linear medium (ϵ,μ) between:

$$\widehat{C} = \epsilon \frac{w}{d}; \qquad \widehat{L} = \mu \frac{d}{w};$$
 (7.4)

$$\epsilon/\epsilon_0 = 2$$
 to 6 for plastics; 4 to 8 for porcelain, glasses; (7.5)

$$\mu/\mu_0 \simeq 1 \ . \tag{7.6}$$

Coaxial cable of inner radius r_1 , outer radius r_2 :

$$\widehat{C} = \frac{2\pi \epsilon}{\ln (r_2/r_1)} \; ; \quad \widehat{L} = \frac{\mu}{2\pi} \ln (r_2/r_1) \; .$$
 (7.7)

Transmission lines (no loss):

Impedance:
$$Z = \sqrt{\hat{L}/\hat{C}}$$
. (7.8)

Velocity:
$$v = 1/\sqrt{\hat{L} \hat{C}} = 1/\sqrt{\mu \epsilon}$$
. (7.9)

7.3. Synchrotron radiation (CGS units)

For a particle of charge e, velocity $v=\beta c$, and energy $E=\gamma mc^2$, traveling in a circular orbit of radius R, the classical energy loss per revolution δE is

$$\delta E = \frac{4\pi}{3} \, \frac{e^2}{R} \, \beta^3 \, \gamma^4 \, . \tag{7.10}$$

For high-energy electrons or positrons ($\beta \approx 1$), this becomes

$$\delta E \text{ (in MeV)} \approx 0.0885 \ [E(\text{in GeV})]^4 / R(\text{in m}) \ .$$
 (7.11)

For $\gamma\gg 1$, the energy radiated per revolution into the photon energy interval $d(\hbar\omega)$ is

$$dI = \frac{8\pi}{9} \alpha \gamma F(\omega/\omega_c) d(h\omega) , \qquad (7.12)$$

where $\alpha = e^2/\hbar c$ is the fine-structure constant and

$$\omega_c = \frac{3\gamma^3 c}{2R} \tag{7.13}$$

is the critical frequency. The normalized function F(y) is

$$F(y) = \frac{9}{8\pi} \sqrt{3} \ y \ \int_y^\infty \ K_{5/3} \left(x \right) \ dx \ , \tag{7.14}$$

where $K_{5/3}\left(x\right)$ is a modified Bessel function of the third kind. For electrons or positrons,

$$\hbar\omega_c \,(\mathrm{in\ keV}) \approx 2.22 \,[E(\mathrm{in\ GeV})]^3/R(\mathrm{in\ m}) \,.$$
 (7.15)

Fig. 7.1 shows F(y) over the important range of y.

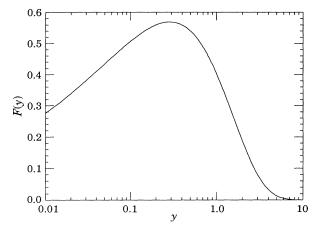

Figure 7.1: The normalized synchrotron radiation spectrum F(y).

For $\gamma \gg 1$ and $\omega \ll \omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx 3.3\alpha \, (\omega R/c)^{1/3} \quad , \tag{7.16}$$

whereas for

 $\gamma \gg 1$ and $\omega \gtrsim 3\omega_c$,

$$\frac{dI}{d(h\omega)} \approx \sqrt{\frac{3\pi}{2}} \, \alpha \, \gamma \left(\frac{\omega}{\omega_c}\right)^{1/2} e^{-\omega/\omega_c} \left[1 + \frac{55}{72} \frac{\omega_c}{\omega} + \ldots\right] \quad . \tag{7.17}$$

The radiation is confined to angles $\lesssim 1/\gamma$ relative to the instantaneous direction of motion. The mean number of photons emitted per revolution is

$$N_{\gamma} = \frac{5\pi}{\sqrt{3}} \alpha \gamma \,\,, \tag{7.18}$$

and the mean energy per photon is

$$\langle h\omega \rangle = \frac{8}{15\sqrt{3}} h\omega_c \ . \tag{7.19}$$

When $\langle \hbar \omega \rangle \gtrsim O(E)$, quantum corrections are important.

See J.D. Jackson, Classical Electrodynamics, $2^{\rm nd}$ edition (John Wiley & Sons, New York, 1975) for more formulae and details. In his book, Jackson uses a definition of ω_c that is twice as large as the customary one given above.

8. NAMING SCHEME FOR HADRONS

8.1. Introduction

We introduced in the 1986 edition [1] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of the light $(u,\,d,\,{\rm and}\,s)$ quarks. Old and new names were listed alongside until 1994. Names also change from edition to edition because some characteristic like mass or spin changes. The Summary Tables give both the new and old names whenever a change occurred.

8.2. "Neutral-flavor" mesons (S=C=B=T=0)

Table 8.1 shows the names for mesons having the strangeness and all heavy-flavor quantum numbers equal to zero. The scheme is designed for all ordinary non-exotic mesons, but it will work for many exotic types too, if needed.

Table 8.1: Symbols for mesons with the strangeness and all heavy-flavor quantum numbers equal to zero.

	$J^{PC} =$	$\begin{cases} 0^{-+} \\ 2^{-+} \\ \vdots \end{cases}$	1 ⁺⁻ 3 ⁺⁻ :	1 2 :	0 ⁺⁺ 1 ⁺⁺ :
$q\overline{q}$ content	$^{2S+1}L_J =$	$^1(L \mathrm{even})_J$	$^1(L \operatorname{odd})_J$	$^3(L {\rm even})_J$	$^3(L \text{ odd})_J$
$\overline{u\overline{d},u\overline{u}-d\overline{d},}$		π	b	ρ	\overline{a}
$\frac{d\overline{d} + u\overline{u}}{\text{and/or } s\overline{s}}$	$ \} (I=0)$	η,η'	h,h'	ω,ϕ	f,f'
$c\overline{c}$		η_c	h_c	ψ^{\dagger}	χ_c
$b\overline{b}$		η_b	h_b	Υ	χ_b
$t\bar{t}$		η_t	h_t	θ	χ_t

[†]The J/ψ remains the J/ψ .

First, we assign names to those states with quantum numbers compatible with being $q\overline{q}$ states. The rows of the Table give the possible $q\overline{q}$ content. The columns give the possible parity/charge-conjugation states,

$$PC = -+, +-, --, \text{ and } ++;$$

these combinations correspond one-to-one with the angular-momentum state $^{2S+1}L_J$ of the $q\overline{q}$ system being

$$^{1}(L \text{ even})_{J}$$
, $^{1}(L \text{ odd})_{J}$, $^{3}(L \text{ even})_{J}$, or $^{3}(L \text{ odd})_{J}$.

Here $S,\ L,$ and J are the spin, orbital, and total angular momenta of the $q\overline{q}$ system. The quantum numbers are related by

$$P = (-1)^{L+1}$$
, $C = (-1)^{L+S}$, and G parity $= (-1)^{L+S+I}$,

where of course the C quantum number is only relevant to neutral mesons.

The entries in the Table give the meson names. The spin J is added as a subscript except for pseudoscalar and vector mesons, and the mass is added in parentheses for mesons that decay strongly. However, for the lightest meson resonances, we omit the mass.

Measurements of the mass, quark content (where relevant), and quantum numbers $I,\ J,\ P,$ and C (or G) of a meson thus fix its symbol. Conversely, these properties may be inferred unambiguously from the symbol.

If the main symbol cannot be assigned because the quantum numbers are unknown, X is used. Sometimes it is not known whether a meson is mainly the isospin-0 mix of $u\overline{u}$ and $d\overline{d}$ or is mainly $s\overline{s}$. A prime (or pair ω , ϕ) may be used to distinguish two such mixing states.

We follow custom and use spectroscopic names such as $\Upsilon(1S)$ as the primary name for most of those ψ , Υ , and χ states whose spectroscopic identity is known. We use the form $\Upsilon(9460)$ as an alternative, and as the primary name when the spectroscopic identity is not known.

Names are assigned for $t\overline{t}$ mesons, although the top quark is evidently so heavy that it is expected to decay too rapidly for bound states to form.

Gluonium states or other mesons that are not $q\overline{q}$ states are, if the quantum numbers are *not* exotic, to be named just as are the $q\overline{q}$ mesons. Such states will probably be difficult to distinguish from $q\overline{q}$ states and will likely mix with them, and we make no attempt to distinguish those "mostly gluonium" from those "mostly $q\overline{q}$."

An "exotic" meson with J^{PC} quantum numbers that a $q\overline{q}$ system cannot have, namely $J^{PC}=0^{--},0^{+-},1^{-+},2^{+-},3^{-+},\cdots$, would use the same symbol as does an ordinary meson with all the same quantum numbers as the exotic meson except for the C parity. But then the J subscript may still distinguish it; for example, an isospin-0 1⁻⁺ meson could be denoted ω_1 .

8.3. Mesons with nonzero S, C, B, and/or T

Since the strangeness or a heavy flavor of these mesons is nonzero, none of them are eigenstates of charge conjugation, and in each of them one of the quarks is heavier than the other. The rules are:

1. The main symbol is an upper-case italic letter indicating the heavier quark as follows:

$$s \to \overline{K}$$
 $c \to D$ $b \to \overline{B}$ $t \to T$.

We use the convention that the flavor and the charge of a quark have the same sign. Thus the strangeness of the s quark is negative, the charm of the c quark is positive, and the bottom of the b quark is negative. In addition, I_3 of the u and d quarks are positive and negative, respectively. The effect of this convention is as follows: Any flavor carried by a charged meson has the same sign as its charge. Thus the K^+ , D^+ , and B^+ have positive strangeness, charm, and bottom, respectively, and all have positive I_3 . The D_s^+ has positive charm and strangeness. Furthermore, the $\Delta({\rm flavor}) = \Delta Q$ rule, best known for the kaons, applies to every flavor.

- 2. If the lighter quark is not a u or a d quark, its identity is given by a subscript. The D_s^+ is an example.
- 3. If the spin-parity is in the "normal" series, $J^P=0^+,1^-,2^+,\cdots$, a superscript "*" is added.
- The spin is added as a subscript except for pseudoscalar or vector mesons.

8.4. Baryons

The symbols N, Δ , A, Σ , Ξ , and Ω used for more than 30 years for the baryons made of light quarks (u, d, and s quarks) tell the isospin and quark content, and the same information is conveyed by the symbols used for the baryons containing one or more heavy quarks (c, b, and t quarks). The rules are:

- 1. Baryons with three u and/or d quarks are N's (isospin 1/2) or Δ 's (isospin 3/2).
- 2. Baryons with $two\ u$ and/or d quarks are A's (isospin 0) or Σ 's (isospin 1). If the third quark is a $c,\ b,$ or t quark, its identity is given by a subscript.
- Baryons with one u or d quark are \(\mathcal{Z}\)'s (isospin 1/2). One or two subscripts are used if one or both of the remaining quarks are heavy: thus \(\mathcal{Z}_c\), \(\mathcal{Z}_{cc}\), \(\mathcal{Z}_b\), etc.
- Baryons with no u or d quarks are Ω's (isospin 0), and subscripts indicate any heavy-quark content.

In short, the number of u plus d quarks together with the isospin determine the main symbol, and subscripts indicate any content of heavy quarks. A Σ always has isospin 1, an Ω always has isospin 0,

9. QUANTUM CHROMODYNAMICS

9.1. The QCD Lagrangian

Prepared August 1995 by I. Hinchliffe.

Quantum Chromodynamics (QCD), the gauge field theory which describes the strong interactions of colored quarks and gluons, is one of the components of the $SU(3)\times SU(2)\times U(1)$ Standard Model. A quark of specific flavor (such as a charm quark) comes in 3 colors; gluons come in eight colors; hadrons are color-singlet combinations of quarks, anti-quarks, and gluons. The Lagrangian describing the interactions of quarks and gluons is (up to gauge-fixing terms)

$$L_{\text{QCD}} = -\frac{1}{4} F_{\mu\nu}^{(a)} F^{(a)\mu\nu} + i \sum_{q} \overline{\psi}_{q}^{i} \gamma^{\mu} (D_{\mu})_{ij} \psi_{q}^{j} - \sum_{q} m_{q} \overline{\psi}_{q}^{i} \psi_{qi} , \qquad (9.1)$$

$$F_{\mu\nu}^{(a)} = \partial_{\mu} A_{\nu}^{a} - \partial_{\nu} A_{\mu}^{a} + g_{s} f_{abc} A_{\mu}^{b} A_{\nu}^{c} , \qquad (9.2)$$

$$(D_{\mu})_{ij} = \delta_{ij} \ \partial_{\mu} - ig_s \sum_{s} \frac{\lambda_{i,j}^a}{2} A_{\mu}^a \ ,$$
 (9.3)

where g_s is the QCD coupling constant, and the f_{abc} are the structure constants of the SU(3) algebra (the λ matrices and values for f_{abc} can be found in "SU(3) Isoscalar Factors and Representation Matrices," Sec. 32 of this Review). The $\psi_q^i(x)$ are the 4-component Dirac spinors associated with each quark field of (3) color i and flavor q, and the $A_\mu^a(x)$ are the (8) Yang-Mills (gluon) fields. A complete list of the Feynman rules which derive from this Lagrangian, together with some useful color-algebra identities, can be found in Ref. 1.

The principle of "asymptotic freedom" (see below) determines that the renormalized QCD coupling is small only at high energies, and it is only in this domain that high-precision tests—similar to those in QED—can be performed using perturbation theory. Nonetheless, there has been in recent years much progress in understanding and quantifying the predictions of QCD in the nonperturbative domain, for example, in soft hadronic processes and on the lattice [2]. This short review will concentrate on QCD at short distances (large momentum transfers), where perturbation theory is the standard tool. It will discuss the processes that are used to determine the coupling constant of QCD. Other recent reviews of the coupling constant measurements may be consulted for a different perspective [3].

9.2. The QCD coupling and renormalization scheme

The renormalization scale dependence of the effective QCD coupling $\alpha_s=g_s^2/4\pi$ is controlled by the β -function:

$$\mu \frac{\partial \alpha_s}{\partial \mu} = -\frac{\beta_0}{2\pi} \alpha_s^2 - \frac{\beta_1}{4\pi^2} \alpha_s^3 - \frac{\beta_2}{64\pi^3} \alpha_s^4 - \cdots, \qquad (9.4a)$$

$$\beta_1 = 51 - \frac{19}{3} n_f \,, \tag{9.4c}$$

$$\beta_2 = 2857 - \frac{5033}{9}n_f + \frac{325}{27}n_f^2 ; \qquad (9.4d)$$

where n_f is the number of quarks with mass less than the energy scale μ . In solving this differential equation for α_s , a constant of integration is introduced. This constant is the one fundamental constant of QCD that must be determined from experiment. The most sensible choice for this constant is the value of α_s at a fixed-reference scale μ_0 , but it is more conventional to introduce the dimensional parameter Λ , since this provides a parametrization of the μ dependence of α_s . The definition of Λ is arbitrary. One way to define it (adopted here) is to write a solution of Eq. (9.4) as an expansion in inverse powers of $\ln (\mu^2)$:

$$\alpha_s(\mu) = \frac{4\pi}{\beta_0 \ln(\mu^2/\Lambda^2)} \left[1 - \frac{2\beta_1}{\beta_0^2} \frac{\ln\left[\ln(\mu^2/\Lambda^2)\right]}{\ln(\mu^2/\Lambda^2)} + \frac{4\beta_1^2}{\beta_0^4 \ln^2(\mu^2/\Lambda^2)} \right] \times \left(\left(\ln\left[\ln(\mu^2/\Lambda^2)\right] - \frac{1}{2} \right)^2 + \frac{\beta_2\beta_0}{8\beta_1^2} - \frac{5}{4} \right) \right].$$
(9.5a)

The last term in this expansion is

$$\mathcal{O}\left(\frac{\ln^2\left[\ln\left(\mu^2/\Lambda^2\right)\right]}{\ln^3\left(\mu^2/\Lambda^2\right)}\right) , \tag{9.5b}$$

and is usually neglected in the definition of Λ . We choose to include it even though its effect on $\alpha_s(\mu)$ is smaller than the experimental errors. For a fixed value of $\alpha_s(M_Z)$, the inclusion of this term shifts the value of Λ by ~ 15 MeV. This solution illustrates the asymptotic freedom property: $\alpha_s \to 0$ as $\mu \to \infty$. Alternative definitions of Λ are possible. We adopt this as the standard. Values given by experiments using other definitions are adjusted as needed to meet our definition.

Consider a "typical" QCD cross section which, when calculated perturbatively, starts at $\mathcal{O}(\alpha_s)$:

$$\sigma = A_1 \alpha_s + A_2 \alpha_s^2 + \cdots (9.6)$$

The coefficients A_1 , A_2 come from calculating the appropriate Feynman diagrams. In performing such calculations, various divergences arise, and these must be regulated in a consistent way. This requires a particular renormalization scheme (RS). The most commonly used one is the modified minimal subtraction $(\overline{\text{MS}})$ scheme [4]. This involves continuing momentum integrals from 4 to 4–2 ϵ dimensions, and then subtracting off the resulting $1/\epsilon$ poles and also $(\ln 4\pi - \gamma_E)$, which is another artifact of continuing the dimension. (Here γ_E is the Euler-Mascheroni constant.) To preserve the dimensionless nature of the coupling, a mass scale μ must also be introduced: $g \to \mu^\epsilon g$. The finite coefficients A_i thus obtained depend implicitly on the renormalization convention used and explicitly on the scale μ .

The first two coefficients (β_0, β_1) in Eq. (9.4) are independent of the choice of RS's. In contrast, the coefficients of terms proportional to α_s^n for n>3 are RS-dependent. The form given above for β_2 is in the $\overline{\rm MS}$ scheme. It has become conventional to use the $\overline{\rm MS}$ scheme for calculating QCD cross sections beyond leading order.

The fundamental theorem of RS dependence is straightforward. Physical quantities, in particular the cross section, calculated to all orders in perturbation theory, do not depend on the RS. It follows that a truncated series does exhibit RS dependence. In practice, QCD cross sections are known to leading order (LO), or to next-to-leading order (NLO), or in a few cases, to next-to-next-to-leading order (NNLO); and it is only the latter two cases, which have reduced RS dependence, that are useful for precision tests. At NLO the RS dependence is completely given by one condition which can be taken to be the value of the renormalization scale μ . At NNLO this is not sufficient, and μ is no longer equivalent to a choice of scheme; both must now be specified. One, therefore, has to address the question of what is the "best" choice for μ . There is no definite answer to this question—higher-order corrections do not "fix" the scale, rather they render the theoretical predictions less sensitive to its variation.

One could imagine that choosing a scale μ characteristic of the typical energy scale (E) in the process would be most appropriate. In general, a poor choice of scale generates terms of order $\ln{(E/\mu)}$ in the A_i 's. Various methods have been proposed including choosing: the scale for which the next-to-leading-order correction vanishes ("Fastest Apparent Convergence [5]"); the scale for which the next-to-leading-order prediction is stationary [6], (i.e.), the value of μ where $d\sigma/d\mu=0$); or the scale dictated by the effective charge scheme [7] or by the BLM scheme [8]. By comparing the values of α_s that different reasonable schemes give, an estimate of theoretical errors can be obtained.

An important corollary is that if the higher-order corrections are naturally small, then the additional uncertainties introduced by the μ dependence are likely to be less than the experimental measurement errors. There are some processes, however, for which the choice of scheme can influence the extracted value of $\Lambda_{\overline{\rm MS}}$. There is no resolution to this problem other than to try to calculate even more terms in the perturbation series. It is important to note that, since the perturbation series is an asymptotic expansion, there is a limit to the precision with which any theoretical quantity can be

calculated. In some processes, the highest-order perturbative terms may be comparable in size to nonperturbative corrections (sometimes called higher-twist or renormalon effects, for a discussion see [9]); an estimate of these terms and their uncertainties is required if a value of α_s is to be extracted.

In the cases where the higher-order corrections to a process are known and are large, some caution should be exercised when quoting the value of α_s . In what follows, we will attempt to indicate the size of the theoretical uncertainties on the extracted value of α_s . There are two simple ways to determine this error. First, we can estimate it by comparing the value of $\alpha_s(\mu)$ obtained by fitting data using the QCD formula to highest known order in α_s , and then comparing it with the value obtained using the next-to-highest-order formula (μ is chosen as the typical energy scale in the process). The corresponding A's are then obtained by evolving $\alpha_s(\mu)$ to $\mu = m_Z$ using Eq. (9.4) to the same order in α_s as the fit, and then converting to $\Lambda^{(4)}$ using Eq. (9.7). Alternatively, we can vary the value of μ over a reasonable range, extracting a value of Λ for each choice of μ . This method is of its nature imprecise, since "reasonable" involves a subjective judgment. In either case, if the perturbation series is well behaved, the resulting error on Λ will be small.

In the above discussion we have ignored quark-mass effects, i.e., we have assumed an idealized situation where quarks of mass greater than μ are neglected completely. In this picture, the β -function coefficients change by discrete amounts as flavor thresholds are crossed when integrating the differential equation for α_s . It follows that, for a relationship such as Eq. (9.5) to remain valid for all values of μ , Λ must also change as flavor thresholds are crossed. This leads to the concept of a different Λ for each range of μ corresponding to an effective number of massless quarks: $\Lambda \to \Lambda^{(n_f)}$. There is some arbitrariness in how this relationship is set up. As an idealized case, consider QCD with $n_f - 1$ massless quarks and one quark of mass M. Now imagine an experiment at energy scale μ ; for example, this could be $e^+e^- \to hadrons$ at center-of-mass energy μ . If $\mu \gg M$, the mass M is negligible and the process is well described by QCD with n_f massless flavors and its parameter $\Lambda^{(n_f)}$ up to terms of order M^2/μ^2 . Conversely if $\mu \ll M$, the heavy quark plays no role and the process is well described by QCD with n_f-1 massless flavors and its parameter $\Lambda^{(n_f-1)}$ up to terms of order μ^2/M^2 . If $\mu \sim M$, the effects of the quark mass are process-dependent and cannot be absorbed into the

A mass scale μ' is chosen where the relationship between $\Lambda^{(n_f-1)}$ and $\Lambda^{(n_f)}$ will be fixed. μ' should be of order M and the relationship should not depend on it. A prescription has been given [10] which has this property. We use this procedure choosing $\mu' = M_Q$, where M_Q is the mass of the value of the running quark mass defined in the $\overline{\text{MS}}$ scheme (see the note on "Quark Masses" in the Particle Listings for more details), i.e., where $M_{\overline{\text{MS}}}(M_Q) = M_Q$. Then [10]

$$\begin{split} \beta_0^{n_f-1} \ln \left(\frac{\Lambda^{(n_f)}}{\Lambda^{(n_f-1)}} \right)^2 &= (\beta_0^{n_f} - \beta_0^{n_f-1}) \cdot \ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2 \\ &+ 2 \left(\frac{\beta_1^{n_f}}{\beta_0^{n_f}} - \frac{\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \right) \cdot \ln \left[\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2 \right] \\ &- \frac{2\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \cdot \ln \left(\frac{\beta_0^{n_f}}{\beta_0^{n_f-1}} \right) \cdot \ln \left[\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2 \right] \\ &+ \frac{4 \frac{\beta_1^{n_f}}{(\beta_0^{n_f})^2} \left(\frac{\beta_1^{n_f}}{\beta_0^{n_f}} - \frac{\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \right) \cdot \ln \left[\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2 \right]}{\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2} \\ &+ \frac{\frac{1}{\beta_0^{n_f}} \left[\left(\frac{2\beta_1^{n_f}}{\beta_0^{n_f}} \right)^2 - \left(\frac{2\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \right)^2 - \frac{2\beta_2^{n_f}}{\beta_0^{n_f}} + \frac{2\beta_2^{n_f-1}}{\beta_0^{n_f-1}} - \frac{14}{9} \right]}{\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2} \;. \end{split}$$

This result is valid to order α_s^3 (or alternatively to terms of order $1/\ln^2[(M_Q/\Lambda^{(n_f)})^2]$).

An alternative matching procedure can be used [11]. This procedure requires the equality $\alpha_s(\mu)^{(n_f)} = \alpha_s(\mu)^{(n_f-1)}$ for $\mu = M_Q$. This matching is somewhat arbitrary; a different relation between $\Lambda^{(n_f)}$ and $\Lambda^{(n_f-1)}$ would result if $\mu = M_Q/2$ were used. In practice, the differences between these procedures are very small. $\Lambda^{(5)} = 200$ MeV corresponds to $\Lambda^{(4)} = 289$ MeV in the scheme of Ref. 11 and $\Lambda^{(4)} = 280$ MeV in the scheme adopted above. Note that the differences between $\Lambda^{(5)}$ and $\Lambda^{(4)}$ are numerically very significant.

Data from deep-inelastic scattering are in a range of energy where the bottom quark is not readily excited, and hence, these experiments quote $\Lambda_{\overline{\rm MS}}^{(4)}$. Most data from PEP, PETRA, TRISTAN, LEP, and SLC quote a value of $\Lambda_{\overline{\rm MS}}^{(5)}$ since these data are in an energy range where the bottom quark is light compared to the available energy. We have converted it to $\Lambda_{\overline{\rm MS}}^{(4)}$ as required. A few measurements, including the lattice gauge theory values from the ψ system and from τ decay are at sufficiently low energy that $\Lambda_{\overline{\rm MS}}^{(3)}$ is appropriate.

We turn now to a discussion of renormalization-scheme dependence in QCD. Although necessarily rather technical, this discussion is vital to understanding how α_s (or Λ) values can be measured and compared. See the review by Duke and Roberts [12] for further details

In order to compare the values of α_s from various experiments, they must be evolved using the renormalization group to a common scale. For convenience, this is taken to be the mass of the Z boson. This evolution uses third-order perturbation theory and can introduce additional errors particularly if extrapolation from very small scales is used. The variation in the charm and bottom quark masses $(m_b=4.3\pm0.2$ and $m_c=1.3\pm0.3$ are used) can also introduce errors. These result in a fixed value of $\alpha_s(2~{\rm GeV})$, giving an uncertainty in $\alpha_s(M_Z)=\pm0.001$ if only perturbative evolution is used. There could be additional errors from nonperturbative effects that enter at low energy. All values are in the $\overline{\rm MS}$ scheme unless otherwise noted.

9.3. QCD in deep-inelastic scattering

The original and still one of the most powerful quantitative tests of perturbative QCD is the breaking of Bjorken scaling in deep-inelastic lepton-hadron scattering. In the leading-logarithm approximation, the measured structure functions $F_i(x,Q^2)$ are related to the quark distribution functions $q_i(x,Q^2)$ according to the naive parton model, by the formulae in "Cross-section Formulae for Specific Processes," Sec. 35 of this *Review*. (In that section, q_i is denoted by the notation f_q). In describing the way in which scaling is broken in QCD, it is convenient to define nonsinglet and singlet quark distributions:

$$F^{NS} = q_i - q_j$$
 $F^S = \sum_i (q_i + \overline{q}_i)$ (9.8)

The nonsinglet structure functions have nonzero values of flavor quantum numbers such as isospin or baryon number. The variation with Q^2 of these is described by the so-called DGLAP equations [13,14]:

$$Q^2 \; \frac{\partial F^{NS}}{\partial Q^2} = \frac{\alpha_s(|Q|)}{2\pi} P^{qq} * F^{NS} \eqno(9.9a)$$

$$Q^2 \frac{\partial}{\partial Q^2} \begin{pmatrix} F^S \\ G \end{pmatrix} = \frac{\alpha_s(|Q|)}{2\pi} \begin{pmatrix} P^{qq} & 2n_f P^{qg} \\ P^{gq} & P^{gg} \end{pmatrix} * \begin{pmatrix} F^S \\ G \end{pmatrix}$$
(9.9b)

where * denotes a convolution integral:

$$f * g = \int_{x}^{1} \frac{dy}{y} f(y) g\left(\frac{x}{y}\right) . \tag{9.10}$$

The leading-order Altarelli-Parisi [14] splitting functions are

$$P^{qq} = \frac{4}{3} \left[\frac{1+x^2}{(1-x)_+} \right] + 2\delta(1-x) , \qquad (9.11a)$$

$$P^{qg} = \frac{1}{2} \left[x^2 + (1 - x)^2 \right] , \qquad (9.11b)$$

$$P^{gq} = \frac{4}{3} \left[\frac{1 + (1 - x)^2}{x} \right] , \qquad (9.11c)$$

$$P^{gg} = 6 \left[\frac{1-x}{x} + x(1-x) + \frac{x}{(1-x)_{+}} + \frac{11}{12} \delta(1-x) \right] - \frac{n_f}{3} \delta(1-x) . \tag{9.11d}$$

Here the gluon distribution $G(x,Q^2)$ has been introduced and $1/(1-x)_+$ means

$$\int_0^1 dx \frac{f(x)}{(1-x)_+} = \int_0^1 dx \, \frac{f(x) - f(1)}{(1-x)} \,. \tag{9.12}$$

The precision of contemporary experimental data demands that higher-order corrections also be included [15]. The above results are for massless quarks. Algorithms exist for the inclusion of nonzero quark masses [16]. At low Q^2 values, there are also important "higher-twist" (HT) contributions of the form:

$$F_i(x, Q^2) = F_i^{(LT)}(x, Q^2) + \frac{F_i^{(HT)}(x, Q^2)}{Q^2} + \cdots$$
 (9.13)

Leading twist (LT) indicates a term whose behavior is predicted by perturbative QCD. These corrections are numerically important only for $Q^2 < \mathcal{O}(10\,\mathrm{GeV}^2)$ except for x very close to 1.

A detailed review of the current status of the experimental data can be found, for example, in Refs. [17–20], and only a brief summary will be presented here. We shall only include determinations of Λ from the recently published results; the earlier editions of this *Review* should be consulted for the earlier data. In any event, the recent results will dominate the average since their errors are smaller. Data have now appeared from HERA at much smaller values of x than the previous data. They provide valuable information about the shape of the antiquark and gluon distribution functions at $x \sim 10^{-3}$ [21].

From Eq. (9.9), it is clear that a nonsinglet structure function offers in principle the most precise test of the theory, since the Q^2 evolution is independent of the unmeasured gluon distribution. The CCFR collaboration fit to the Gross-Llewellyn Smith sum rule [22] is known to order α_s^3 [23]

$$\begin{split} &\int_0^1 dx (F_3^{\overline{\nu}p}(x,Q^2) + F_3^{\nu p}(x,Q^2)) = \\ &3 \left[(1 - \frac{\alpha_s}{\pi} (1 + 3.58 \frac{\alpha_s}{\pi} + 19.0 (\frac{\alpha_s}{\pi})^2) - \Delta HT \right] , \end{split} \tag{9.14}$$

where the higher-twist contribution $\Delta HT = (0.09 \pm 0.045)/Q^2$ [23,24]. Using the CCFR data [25], this gives α_s (1.76 GeV) = 0.26 \pm 0.035 (expt.) \pm 0.03 (theory). The error from higher-twist terms dominates the theoretical error, the higher-twist term being approximately 50% larger than the α_s^3 term.

A measurement of Λ has been made using F_3 in neutrino scattering [27]. The result is $\Lambda_{\overline{\rm MS}}^{(4)}=179\pm36\pm41$ MeV. The errors are statistical and systematic but do not include (theoretical) errors arising from the choice of μ^2 . Measurements involving singlet-dominated structure functions, such as F_2 , result in correlated measurements of $\Lambda_{\overline{\rm MS}}^{(4)}$ and the gluon distribution. By utilizing high-statistics data at large x (> 0.25) and large Q^2 , where F_2 behaves like an nonsinglet and F_3 at smaller x, a nonsinglet fit can be performed with better statistical precision, and hence, the error on the measured value of $\Lambda_{\overline{\rm MS}}^{(4)}$ is much reduced. CCFR gives $\Lambda_{\overline{\rm MS}}^{(4)}=210\pm28\pm41$ MeV [27] from $F_2(\nu N)$ and $F_3(\nu N)$. There is an additional uncertainty of ±59 MeV from the choice of scale. The NMC collaboration [28] gives $\alpha_s(7~{\rm GeV}^2)=0.264\pm0.018({\rm stat.})\pm0.070({\rm syst.})\pm0.013(~{\rm higher-twist})$. The systematic error is larger than the CCFR result, partially because the data are at smaller values of x and the gluon distribution is

more important. A reanalysis [29] of EMC data [30] gives $\Lambda_{\overline{\rm MS}}^{(4)}=211\pm80\pm80~{\rm MeV}$ from $F_2(\nu N)$. Finally a combined analysis [31] of SLAC [32] and BCDMS [33] data gives $\Lambda_{\overline{\rm MS}}^{(4)}=263\pm42\pm55~{\rm MeV}$. Here the systematic error is an estimate of the uncertainty due to the choice of Q^2 used in the argument of α_s , and in the scale at which the structure functions (factorization scale) used in the QCD calculation are evaluated.

The results from Refs. [27–29] and [31] can be combined to give $\alpha_s(M_Z)=0.112\pm0.002\pm0.004$, or equivalently $\Lambda_{\overline{\rm MS}}^{(4)}=234\pm26\pm50$ MeV. Here the first error is a combination of statistical and systematic errors, and the second error is due to the scale uncertainty. This result is an average of the results weighted by their statistical and systematic errors. The scale error which is common to all is then reapplied to the average.

The spin-dependent structure functions can also be used to determine α_s . Here the values of $Q^2 \sim 2.5 \; \mathrm{GeV}^2$ are small and higher-twist corrections are again important. The values extracted are consistent with the average quote below [26].

At very small values of x and large Q^2 , the x-dependence of the structure functions is predicted by perturbative QCD [34]. Here terms to all orders in $\alpha_s \ln(1/x)$ are summed. The data from HERA [21] on $F_2^{ep}(x,Q^2)$ have been fitted to the this form [35], including the NLO terms which are required to fix the Q^2 scale. The data are dominated by $4 \text{ GeV}^2 < Q^2 < 100 \text{ GeV}^2$. The fit gives $\alpha_s(M_Z) = 0.120 \pm 0.005 \text{ (expt.)} \pm 0.009 \text{ (theory)}$. The dominant part of the theoretical error is from the scale dependence. The fit neglects from this source cannot be estimated and are not included in the quoted error. This result is not averaged with the other ones from scaling violations, since the values there are derived from the Q^2 dependence alone, and this possible source of error is not present.

Typically, Λ is extracted from the data by parametrizing the parton densities in a simple analytic way at some Q_0^2 , evolving to higher Q^2 using the next-to-leading-order evolution equations, and fitting globally to the measured structure functions to obtain $\Lambda_{\overline{\rm MS}}^{(4)}$. Thus, an important by-product of such studies is the extraction of parton densities at a fixed-reference value of Q_0^2 . These can then be evolved in Q^2 and used as input for phenomenological studies in hadron-hadron collisions (see below). To avoid having to evolve from the starting Q_0^2 value each time, a parton density is required; it is useful to have available a simple analytic approximation to the densities valid over a range of x and Q^2 values. A package is available from the CERN computer library that includes an exhaustive set of fits [36]. Some of these fits are obsolete. In using a parameterization to predict event rates, a next-to-leading order fit must be used if the process being calculated is known to next-to-leading order in QCD perturbation theory. In such a case, there is an additional scheme dependence; this scheme dependence is reflected in the $\mathcal{O}(\alpha_s)$ corrections that appear in the relations between the structure functions and the quark distribution functions. There are two common schemes: a deep-inelastic scheme where there are no order α_s corrections in the formula for $F_2(x,Q^2)$ and the minimal subtraction scheme. It is important when these next-to-leading order fits are used in other processes (see below), that the same scheme is used in the calculation of the partonic rates.

9.4. QCD in decays of the τ lepton

The semi-leptonic branching ratio of the tau $(\tau \to \nu_{\tau} + hadrons, R_{\tau})$ is an inclusive quantity. It is related to the contribution of hadrons to the imaginary part of the W self energy $(\Pi(s))$. However, it is more inclusive than R since it involves an integral

$$R_{ au} \sim \int_{0}^{m_{ au}^2} rac{ds}{m_{ au}^2} (1 - rac{s}{m_{ au}^2})^2 \ {
m Im} \left(\Pi(s)
ight) \ .$$

Since the scale involved is low, one must take into account nonperturbative (higher-twist) contributions which are suppressed by powers of the τ mass.

$$R_{\tau} = 3.058 \left[1 + \frac{\alpha_s(m_{\tau})}{\pi} + 5.2 \left(\frac{\alpha_s(m_{\tau})}{\pi} \right)^2 + 26.4 \left(\frac{\alpha_s(m_{\tau})}{\pi} \right)^3 + \right.$$

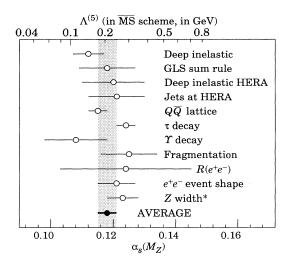

Figure 9.1: Summary of the values of $\alpha_s(M_Z)$ and $\Lambda^{(5)}$ from various processes ordered from top to bottom by increasing energy scale of the measurements. The values shown indicate the process and the measured value of α_s extrapolated up to $\mu = M_Z$. The error shown is the *total* error including theoretical uncertainties. The value denoted by '*' is not used in the average (see text).

$$a\frac{m^2}{m_{\tau}^2} + b\frac{m\psi\overline{\psi}}{m_{\tau}^4} + c\frac{\psi\overline{\psi}\psi\overline{\psi}}{m_{\tau}^6} + \cdots \right]. \tag{9.15}$$

Here a,b, and c are dimensionless constants and m is a light quark mass. The term of order $1/m_{\tau}^2$ is a kinematical effect due to the light quark masses and is consequently very small. The nonperturbative terms are estimated using sum rules [37]. In total, they are estimated to be -0.007 ± 0.004 [38]. This estimate relies on there being no term of order Λ^2/m_{τ}^2 (note that $\frac{\alpha_s(m_{\tau})}{\pi} \sim (\frac{0.5~\text{GeV}}{m_{\tau}})^2$). The a,b, and c can be determined from the data [39] by fitting to moments of the $\Pi(s)$. The values so extracted [40,41] are consistent with the theoretical estimates. If the nonperturbative terms are omitted from the fit, the extracted value of $\alpha_s(m_{\tau})$ decreases by ~ 0.02 .

For $\alpha_s(m_\tau) = 0.37$ the perturbative series for R_τ is $R_\tau \sim$ 3.058(1 + 0.118 + 0.072 + 0.043). The size (estimated error) of the nonperturbative term is 20% (7%) of the size of the order α_s^3 term. The perturbation series in not very well convergent; if the order α_s^3 term is omitted, the extracted value of $\alpha_s(m_\tau)$ increases by 0.05. R_τ , can be extracted from the semi-leptonic branching ratio from the relation $R_{\tau} = 1/(B(\tau \to e\nu\overline{\nu}) - 1.97256$; where $B(\tau \to e\nu\overline{\nu})$ is measured directly or extracted from the lifetime, the muon mass and the muon lifetime assuming universality of lepton couplings. Using the average lifetime of 291.3 \pm 1.6 fs [42] and a τ mass of 1.776.96 \pm 0.30 [43] gives $R_{ au}=3.633\pm0.031$. Assuming e/μ universality, the data give B($\tau \to e\nu\overline{\nu}$) = 0.1780 ± 0.0006 [44]. Averaging these yields $\alpha_s(m_\tau) = 0.370 \pm 0.008$ using the experimental error alone. This result is consistent with measurements reported recently by other collaborations [45,46]. The value of $\alpha_s(m_\tau) = 0.306 \pm 0.017$ quoted by CLEO [41] uses the measured moments and the average value $B(\tau \to e\nu\overline{\nu}) = 0.1810 \pm 0.0012$ from the 1992 edition of this review. We assign a theoretical error equal to 1/2 of the contribution from the order α^3 term and all of the nonperturbative contributions. This then gives $\alpha_s(m_ au) = 0.370 \pm 0.033$ for the final result. Note that the theoretical errors are dominant. The small theoretical errors have been criticized [47].

9.5. QCD in high-energy hadron collisions

There are many ways in which perturbative QCD can be tested in high-energy hadron colliders. The quantitative tests are only useful if the process in question has been calculated beyond leading order in QCD perturbation theory. The production of hadrons with large transverse momentum in hadron-hadron collisions provides a direct probe of the scattering of quarks and gluons: $qq \rightarrow qq, qg \rightarrow qg,$ $gg \to gg$, etc. The present generation of $p\overline{p}$ colliders provide centerof-mass energies which are sufficiently high that these processes can be unambiguously identified in two-jet production at large transverse momentum. Recent higher-order QCD calculations of the jet rates [48] and shapes are in impressive agreement with data [49]. As an example, Fig. 36.7 in this Review shows the inclusive jet cross section at zero pseudorapidity as a function of the jet transverse momentum for $p\overline{p}$ collisions. The QCD prediction combines the parton distributions with the leading-order $2 \rightarrow 2$ parton scattering amplitudes. Data are also available on the angular distribution of jets; these are also in agreement with QCD expectations [50,51].

QCD corrections to Drell-Yan type cross sections (i.e., the production in hadron collisions by quark-antiquark annihilation of lepton pairs of invariant mass Q from virtual photons, or of real W or Z bosons), are known [52]. These $\mathcal{O}(\alpha_s)$ QCD corrections are sizable at small values of Q.

It is interesting to note that the corresponding correction to W and Z production, as measured in $p\overline{p}$ collisions at $\sqrt{s}=0.63$ TeV and $\sqrt{s}=1.8$ TeV, has essentially the same theoretical form and is of order 30%.

The production of W and Z bosons and photons at large transverse momentum can also be used to determine α_s . The leading-order QCD subprocesses are $q\overline{q} \to \gamma g$ and $qg \to \gamma q$. If the parton distributions are taken from other processes and a value of $\Lambda_{\overline{\rm MS}}^{(4)}$ assumed, then an absolute prediction is obtained. Conversely, the data can be used to extract information on quark and gluon distributions and on the value of $\Lambda_{\overline{MS}}^{(4)}$. The next-to-leading-order QCD corrections are known [53,54] (for photons), and for W/Z production [55], and so a precision test is possible in principle. Data exist from the CDF and DØ collaborations [56,57]. The UA2 collaboration [58] has extracted a value of $\alpha_s(M_W) = 0.123 \pm 0.018 ({\rm stat.}) \pm 0.017 ({\rm syst.})$ from the measured ratio $R_W = \frac{\sigma(W+1jet)}{\sigma(W+0jet)}$. The result depends on the algorithm used to define a jet, and the dominant systematic errors due to fragmentation and corrections for underlying events (the former causes jet energy to be lost, the latter causes it to be increased) are connected to the algorithm. The scale at which $\alpha_s(M)$ is to be evaluated is not clear. A change from $\mu = M_W$ to $\mu = M_W/2$ causes a shift of 0.01 in the extracted α_s . The quoted error should be increased to take this into account. There is dependence on the

increased) are connected to the algorithm. The scale at which $\alpha_s(M)$ is to be evaluated is not clear. A change from $\mu=M_W$ to $\mu=M_W/2$ causes a shift of 0.01 in the extracted α_s . The quoted error should be increased to take this into account. There is dependence on the parton distribution functions, and hence, α_s appears explicitly in the formula for R_W , and implicitly in the distribution functions. The DØ collaboration has performed an analysis similar to UA2. They are unable to obtain a fit where the two values of α_s are consistent with one another, and do not quote a value of α_s [59]. The values from this process are no longer used in determining the overall average value of α_s .

9.6. QCD in heavy-quarkonium decay

Under the assumption that the hadronic and leptonic decay widths of heavy $Q\overline{Q}$ resonances can be factorized into a nonperturbative part—dependent on the confining potential—and a calculable perturbative part, the ratios of partial decay widths allow measurements of α_s at the heavy-quark mass scale. The most precise data come from the decay widths of the 1^{--} $J/\psi(1S)$ and \varUpsilon resonances. The total decay width of the \varUpsilon is predicted by perturbative QCD [60]

$$R_{\Upsilon} = \frac{\Gamma(\Upsilon \to \text{hadrons})}{\Gamma(\Upsilon \to \mu^{+}\mu^{-})}$$

$$= \frac{10(\pi^2 - 9)\alpha_s^3(M)}{9\pi\alpha_{\text{em}}^2} \times \left[1 + \frac{\alpha_s}{\pi} \left(-19.4 + \frac{3\beta_0}{2} \left(1.162 + \ln\left(\frac{2M}{M_\Upsilon}\right) \right) \right) \right]. \quad (9.16)$$

Data are available for the \varUpsilon , \varUpsilon' , \varUpsilon'' and ψ . The result is very sensitive to α_s and the data are sufficiently precise $(R_\mu(\varUpsilon)=32.5\pm0.9)$ [61] that the theoretical errors will dominate. There are theoretical corrections to this simple formula due to the relativistic nature of the $Q\overline{Q}$ system; $v^2/c^2\sim0.1$ for the \varUpsilon . They are more severe for the ψ . There are also nonperturbative corrections of the form $\Lambda^2/m_{\varUpsilon}^2$; again these are more severe for the ψ . A fit to \varUpsilon , \varUpsilon' , and \varUpsilon'' [62] gives $\alpha_s(M_Z)=0.108\pm0.001$ (expt.). The results from each state separately and also from the ψ are consistent with each other. There is an uncertainty of order ±0.005 from the choice of scale; the error from v^2/c^2 corrections is a little larger. $\alpha_s(M_Z)=0.108\pm0.010$ is a fair representation of the total error including the possibility of nonperturbative corrections.

9.7. Perturbative QCD in e^+e^- collisions

The total cross section for $e^+e^- \to \text{hadrons}$ is obtained (at low values of \sqrt{s}) by multiplying the muon-pair cross section by the factor $R=3\Sigma_q e_q^2$. The higher-order QCD corrections to this quantity have been calculated, and the results can be expressed in terms of the factor:

$$R = R^{(0)} \left[1 + \frac{\alpha_s}{\pi} + C_2 \left(\frac{\alpha_s}{\pi} \right)^2 + C_3 \left(\frac{\alpha_s}{\pi} \right)^3 + \cdots \right] , \qquad (9.17)$$

where $C_2 = 1.411$ and $C_3 = -12.8$ [63].

 $R^{(0)}$ can be obtained from the formula for $d\sigma/d\Omega$ for $e^+e^- \to f\overline{f}$ by integrating over Ω . The formula is given in Sec. 35.2 of this *Review*. This result is only correct in the zero-quark-mass limit. The $\mathcal{O}(\alpha_s)$ corrections are also known for massive quarks [64]. The principal advantage of determining α_s from R in e^+e^- annihilation is that there is no dependence on fragmentation models, jet algorithms, *etc*.

A comparison of the theoretical prediction of Eq. (9.17) (corrected for the *b*-quark mass), with all the available data at values of \sqrt{s} between 20 and 65 GeV, gives [65] $\alpha_s(35 \text{ GeV}) = 0.146 \pm 0.030$. The size of the order α_s^3 term is of order 40% of that of the order α_s^2 and 3% of the order α_s . If the order α_s^3 term is not included, a fit to the data yields α_s (34 GeV) = 0.142 ± 0.03, indicating that the theoretical uncertainty is smaller than the experimental error.

Measurements of the ratio of hadronic to leptonic width of the Z at LEP and SLC, Γ_h/Γ_μ probe the same quantity as R. Using the average of $\Gamma_h/\Gamma_\mu = 20.788 \pm 0.032$ gives $\alpha_s(M_Z) = 0.123 \pm 0.004 \pm 0.002$ [66]. There are theoretical errors arising from the values of the top-quark and Higgs masses which enter due to electroweak corrections to the Z width and from the choice of scale.

While this method has small theoretical uncertainties from QCD itself, it relies sensitively on the electroweak couplings of the Z to quarks [67]. The experimental results on $\Gamma(Z \to b\overline{b})$ and $\Gamma(Z \to c\overline{c})$ are not in agreement with the Standard Model [68]. If these widths are taken from experiment (rather than from the Standard Model), the extracted vale of $\alpha_s(M_Z)$ is 0.183. If the Standard Model is used for $\Gamma(Z \to c\overline{c})$, $\alpha_s(M_Z) = 0.104$ results. In view of these problems, the value from Γ_h/Γ_μ is not included in the final average.

An alternative method of determining α_s in e^+e^- annihilation is from measuring quantities that are sensitive to the relative rates of two-, three-, and four-jet events. A recent review should be consulted for more details [69] of the issues mentioned briefly here. In addition to simply counting jets, there are many possible choices of such "shape variables": thrust [70], energy-energy correlations [71], planar triple-energy correlations [72], average jet mass, etc. All of these are infrared safe, which means they can be reliably calculated in perturbation theory. The starting point for all these quantities is the multijet cross section. For example, at order α_s , for the process $e^+e^- \to qqg$:

$$\frac{1}{\sigma} \frac{d^2 \sigma}{dx_1 dx_2} = \frac{2\alpha_s}{3\pi} \frac{x_1^2 + x_2^2}{(1 - x_1)(1 - x_2)} , \qquad (9.18)$$

where

$$x_i = \frac{2E_i}{\sqrt{s}} \tag{9.19}$$

are the center-of-mass energy fractions of the final-state (massless) quarks. A distribution in a "three-jet" variable, such as those listed above, is obtained by integrating this differential cross section over an appropriate phase space region for a fixed value of the variable. The order α_s^2 corrections to this process have been computed, as well as the 4-jet final states such as $e^+e^- \to qqgg$ [73].

There are many methods used by the e^+e^- experimental groups to determine α_s from the event topology. The jet-counting algorithm, originally introduced by the JADE collaboration [74], has been used by the LEP groups. Here, particles of momenta p_i and p_j are combined into a pseudo-particle of momentum $p_i + p_j$ if the invariant mass of the pair is less than $y_0\sqrt{s}$. The process is then iterated until no more pairs of particles or pseudo-particles remain. The remaining number is then defined to be the number of jets in the event, and can be compared to the QCD prediction. The Durham algorithm is slightly different: in computing the mass of a pair of partons, it uses $M^2 = 2\min(E_1^2, E_2^2)(1 - \cos\theta_{ij})$ for partons of energies E_i and E_j separated by angle θ_{ij} [75].

There are theoretical ambiguities in the way this process is carried out. Quarks and gluons are massless, whereas the observed hadrons are not, so that the massive jets that result from this scheme (the so-called E-0 scheme) cannot be compared directly to the massless jets of perturbative QCD. Different recombination schemes have been tried, for example combining 3-momenta and then rescaling the energy of the cluster so that it remains massless (p scheme). These schemes result in the same data giving a slightly different values [76,77] of α_s . These differences can be used to determine a systematic error. In addition, since what is observed are hadrons rather than quarks and gluons, a model is needed to describe the evolution of a partonic final state into one involving hadrons, so that detector corrections can be applied. The QCDmatrix elements are combined with a parton-fragmentation model. This model can then be used to correct the data for a direct comparison with the parton calculation. The different hadronization models that are used [78-81] model the dynamics that are controlled by nonperturbative QCD effects which we cannot vet calculate. The fragmentation parameters of these Monte Carlos are tuned to get agreement with the observed data. The differences between these models contribute to the systematic errors. The systematic errors from recombination schemes and fragmentation effects dominate over the statistical and other errors of the LEP/SLD experiments.

The scale M at which $\alpha_s(M)$ is to be evaluated is not clear. The invariant mass of a typical jet (or $\sqrt{sy_0}$) is probably a more appropriate choice than the e^+e^- center-of-mass energy. If the value is allowed to float in the fit to the data, the data tend to prefer values of order $\sqrt{s}/10$ [82]; the exact value depends on the variable that is fitted. The dominant uncertainties arise from the choice of M and from the freedom in the fragmentation Monte Carlos.

The perturbative QCD formulae can break down in special kinematical configurations. For example, the thrust distribution contains terms of the type $\alpha_s \ln^2(1-T)$. The higher orders in the perturbation expansion contain terms of order $\alpha_s^n \ln^m(1-T)$. For $T\sim 1$ (the region populated by 2-jet events), the perturbation expansion is unreliable. The terms with $n\leq m$ can be summed to all orders in α_s [83]. If the jet recombination methods are used higher-order terms involve $\alpha_s^n \ln^m y_0$), these too can be resummed [84]. The resummed results give better agreement with the data at large values of T. Some caution should be exercised in using these resummed results because of the possibility of overcounting; the showering Monte Carlos that are used for the fragmentation corrections also generate some of these leading-log corrections. Different schemes for combining the order α_s^2 and the resummations are available [85]. These different schemes result in shifts in α_s of order ± 0.002 [86].

An average of the recent results from SLD [86], OPAL [87], L3 [88], ALEPH [89], and DELPHI [90], using the combined α_s^2 and resummation fitting to a large set of shape variables, gives $\alpha_s(M_Z) = 0.122 \pm 0.007$. The errors in the values of $\alpha_s(M_Z)$ from

these shape variables are totally dominated by the theoretical uncertainties associated with the choice of scale, and the effects of hadronization Monte Carlos on the different quantities fitted.

Similar studies on event shapes have been undertaken at TRISTAN, at PEP/PETRA, and at CLEO. A combined result from various shape parameters by the TOPAZ collaboration gives α_s (58 GeV) = 0.125 \pm 0.009, using the fixed order QCD result, and α_s (58 GeV) = 0.132 \pm 0.008 (corresponding to $\alpha_s(M_Z)=0.123\pm0.007$), using the same method as in the SLD and LEP average [91].

The measurements of event shapes at PEP/PETRA are summarized in earlier editions of this note. The results are consistent with those from Z decay, but have larger errors. We use α_s (34 GeV) = 0.14 \pm 0.02 [92]. A recent analysis by the TPC group [93] gives α_s (29 GeV) = 0.160 \pm 0.012, using the same method as TOPAZ. This value corresponds to $\alpha_s(M_Z)=0.131\pm0.010$

The CLEO collaboration fits to the order α_s^2 results for the two jet fraction at $\sqrt{s}=10.53$ GeV, and obtains $\alpha_s(10.93)=0.164\pm0.004$ (expt.) ±0.014 (theory) [94]. The dominant systematic error arises from the choice of scale (μ) , and is determined from the range of α_s that results from fit with $\mu=10.53$ GeV, and a fit where μ is allowed to vary to get the lowest χ^2 . The latter results in $\mu=1.2$ GeV. Since the quoted result corresponds to $\alpha_s(1.2)=0.35$, it is by no means clear that the perturbative QCD expression is reliable and the resulting error should, therefore, be treated with caution. A fit to many different variables as is done in the LEP/SLC analyses would give added confidence to the quoted error.

Since the errors in the event shape measurements are dominantly systematic, and are common to the experiments, the results from PEP/PETRA, TRISTAN, LEP, SLC, and CLEO are combined to give $\alpha_s(M_Z)=0.122\pm0.007$. This result is used in forming the final average value of α_s .

The total cross section $e^+e^- \to b\bar{b} + X$ near threshold can be used to determine α_s [95]. The result quoted is $\alpha_s(M_Z) = 0.109 \pm 0.001$. The relevant process is only calculated to leading order and the BLM scheme [8] is used. This results in $\alpha_s(0.632\ m_b)$. If $\alpha_s(m_b)$ is used, the resulting $\alpha_s(M_Z)$ shifts to ~ 0.117 . This result is not used in the average.

9.8. Scaling violations in fragmentation functions

Measurements of the fragmentation function $d_i(z, E)$, being the probability that a hadron of type i be produced with energy zE in e^+e^- collisions at $\sqrt{s}=2E$, can be used to determine α_s . As in the case of scaling violations in structure functions, QCD predicts only the E dependence. Hence, measurements at different energies are needed to extract a value of α_s . Because the QCD evolution mixes the fragmentation functions for each quark flavor with the gluon fragmentation function, it is necessary to determine each of these before α_s can be extracted. The ALEPH collaboration has used data from energies ranging from $\sqrt{s}=22~{\rm GeV}$ to $\sqrt{s}=91$ GeV. A flavor tag is used to discriminate between different quark species, and the longitudinal and transverse cross sections are used to extract the gluon fragmentation function [96]. The result obtained is $\alpha_s(M_Z) = 0.126 \pm 0.007$ (expt.) ± 0.006 (theory) [97]. The theory error is due mainly to the choice of scale. The OPAL collaboration [98] has also extracted the separate fragmentation functions. DELPHI [99] has also performed a similar analysis using data from other experiments at lower energy with the result $\alpha_s(M_Z) = 0.122 \pm 0.012 \pm 0.006$ (theory). An earlier analysis by this collaboration [100], is consistent with this result, but used fixed order QCD. The older result is not used in the average, which is determined to be $\alpha_s(M_Z) = 0.125 \pm 0.006 \pm 0.006$ (theory)

9.9. Jet rates in ep collisions

At lowest order in α_s , the ep scattering process produces a final state of (1+1) jets, one from the proton fragment and the other from the quark knocked out by the process $e+quark \rightarrow e+quark$. At next order in α_s , a gluon can be radiated, and hence a (2+1) jet final state produced. By comparing the rates for these (1+1) and (1+2) jet processes, a value of α_s can be obtained. A NLO QCD calculation is available [101]. The basic methodology is similar to that used in the

jet counting experiments in e^+e^- annihilation discussed above. Unlike those measurements, the ones in ep scattering are not at a fixed value of Q^2 . In addition to the systematic errors associated with the jet definitions, there are additional ones since the structure functions enter into the rate calculations. Results from H1 [102] and ZEUS [103] can be combined to give $\alpha_s(M_Z)=0.121\pm0.004$ (stat.) ±0.008 (syst.). The contributions to the systematic errors from experimental effects (mainly the hadronic energy scale) are comparable to the theoretical ones arising from scale choice, structure functions, and jet definitions. These errors are common to the two measurements; therefore, we have not reduced the systematic error after forming the average.

9.10. Lattice QCD

Lattice gauge theory calculations can be used to calculate the energy levels of a $Q\overline{Q}$ system and then extract α_s . The masses of the $Q\overline{Q}$ states depend only on the quark mass and on α_s . A limitation is that calculations cannot be performed for three light quark flavors. Results are available for zero (quenched approximation) and two light flavors, which allow extrapolation to three. The coupling constant so extracted is in a lattice renormalization scheme, and must be converted to the MS scheme for comparison with other results. Using the mass differences of Υ and Υ' and Υ and χ_b , Davies et al. [104] extract a value of $\alpha_s(M_Z) = 0.115 \pm 0.002$. The result is consistent with an earlier result by the same group based on quenched approximation ($\alpha_s(M_Z) = 0.112 \pm 0.004$) [105]. The error is dominated by the conversion between the coupling constants, which is performed at next-to-leading order in perturbation theory. It is estimated by making an assumption about the size of the NNLO term in this conversion. If it is estimated as one-half of the NLO term, then the resulting value is $\alpha_s(M_Z) = 0.115 \pm 0.003$.

A similar result with larger errors is reported by [106], where results are consistent with $\alpha_s(M_Z)=0.111\pm0.006$. This result confirms that obtained in quenched approximation by [107]. A calculation [108] using the strength of the force between two heavy quarks computed in the quenched approximation obtains a value of $\alpha_s(5~{\rm GeV})$ that is consistent with these results.

The result with a more conservative error $\alpha_s(M_Z)=0.115\pm0.003$ will be used in the average, although a recent reviewer quotes an error of ±0.007 [109].

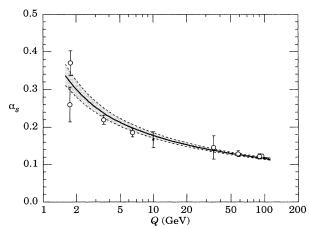

Figure 9.2: Summary of the values of $\alpha_s(Q)$ at the values of Q where they are measured. The lines show the central values and the $\pm 1\sigma$ limits of our average. The figure clearly shows the decrease in $\alpha_s(Q)$ with increasing Q.

9.11. Conclusions

The need for brevity has meant that many other important topics in QCD phenomenology have had to be omitted from this review. One should mention in particular the study of exclusive processes (form factors, elastic scattering, ...), the behavior of quarks and gluons in nuclei, the spin properties of the theory, the interface of soft and hard QCD as manifest, for example, by minijet production and hard diffractive processes, and QCD effects in hadron spectroscopy.

In this short review, we have focused on those high-energy processes which currently offer the most quantitative tests of perturbative QCD. Figure 9.1 shows the values of $\alpha_s(M_Z)$ deduced from the various experiments. Figure 9.2 shows the values and the values of Q where they are measured. This figure clearly shows the experimental evidence for the variation of $\alpha_s(Q)$ with Q.

An average of the values in Fig. 9.1 (except the one from the width of the Z) gives $\alpha_s(M_z) = 0.118$, with a total χ^2 of 9.1 for ten fitted points, showing good consistency among the data. The error on the average, assuming that all of the errors in the contributing results are uncorrelated, is ± 0.0017 , and is surely an underestimate. All the values are dominated by systematic, usually theoretical, errors. The two results with the smallest errors (± 0.003) are the ones from τ decay and lattice gauge theory. If these errors are increased to ± 0.006 , the average is unchanged. There has been discussion of systematic differences in the data. The measurements which are dominated by low-energy (deep-inelastic scattering (not including HERA), τ decay, Υ width, lattice) average to $\alpha_s(M_z) = 0.118$ ($\chi^2 = 8.3$ for 5 points). Results from space-like momentum transfers (all ep results) average to $\alpha_s(M_z) = 0.114 \pm 0.004$, which might indicate some lack of theoretical understanding in comparing the data. Since, in most cases, the dominant error is systematic (mainly theoretical), a more conservative estimate of the final error is obtained by using the smallest of the individual errors on the experimental results, i.e., ± 0.003 . Our average value is then $\alpha_s(M_z) = 0.118 \pm 0.003$, which corresponds to $\Lambda^{(5)} = 209^{+39}_{-33} \text{ MeV}.$

10. STANDARD MODEL OF ELECTROWEAK INTERACTIONS

This section prepared July 1995 by P. Langacker and J. Erler.

The standard electroweak model is based on the gauge group [1] $\mathrm{SU}(2) \times \mathrm{U}(1)$, with gauge bosons W^i_μ , i=1,2,3, and B_μ for the $\mathrm{SU}(2)$ and $\mathrm{U}(1)$ factors, respectively, and the corresponding gauge coupling constants g and g'. The left-handed fermion fields $\psi_i = \begin{pmatrix} \nu_i \\ \ell_i^- \end{pmatrix}$ and $\begin{pmatrix} u_i \\ d_i^\prime \end{pmatrix}$ of the i^{th} fermion family transform as doublets under $\mathrm{SU}(2)$, where $d_i' \equiv \sum_j V_{ij} \ d_j$, and V is the Cabibbo-Kobayashi-Maskawa mixing matrix. (Constraints on V are discussed in the section on the Cabibbo-Kobayashi-Maskawa mixing matrix.) The right-handed fields are $\mathrm{SU}(2)$ singlets. In the minimal model there are three fermion families and a single complex Higgs doublet $\phi \equiv \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$.

After spontaneous symmetry breaking the Lagrangian is

$$\mathcal{L}_{F} = \sum_{i} \overline{\psi}_{i} \left(i \not \partial - m_{i} - \frac{g m_{i} H}{2 M_{W}} \right) \psi_{i}$$

$$- \frac{g}{2\sqrt{2}} \sum_{i} \overline{\psi}_{i} \gamma^{\mu} (1 - \gamma^{5}) (T^{+} W_{\mu}^{+} + T^{-} W_{\mu}^{-}) \psi_{i}$$

$$- e \sum_{i} q_{i} \overline{\psi}_{i} \gamma^{\mu} \psi_{i} A_{\mu}$$

$$- \frac{g}{2 \cos \theta_{W}} \sum_{i} \overline{\psi}_{i} \gamma^{\mu} (g_{V}^{i} - g_{A}^{i} \gamma^{5}) \psi_{i} Z_{\mu} . \tag{10.1}$$

 $\theta_W \equiv \tan^{-1}(g'/g)$ is the weak angle; $e=g\sin\theta_W$ is the positron electric charge; and $A\equiv B\cos\theta_W+W^3\sin\theta_W$ is the (massless) photon field. $W^\pm\equiv (W^1\mp iW^2)/\sqrt{2}$ and $Z\equiv -B\sin\theta_W+W^3\cos\theta_W$ are the massive charged and neutral weak boson fields, respectively. T^+ and T^- are the weak isospin raising and lowering operators. The vector and axial couplings are

$$g_V^i \equiv t_{3L}(i) - 2q_i \sin^2 \theta_W \tag{10.2}$$

$$g_A^i \equiv t_{3L}(i) , \qquad (10.3)$$

where $t_{3L}(i)$ is the weak isospin of fermion i (+1/2 for u_i and ν_i ; -1/2 for d_i and e_i) and q_i is the charge of ψ_i in units of e.

The second term in \mathscr{L}_F represents the charged-current weak interaction [2]. For example, the coupling of a W to an electron and a neutrino is

$$-\frac{e}{2\sqrt{2}\sin\theta_W} \left[W_{\mu}^{-} \ \overline{e} \ \gamma^{\mu} (1 - \gamma^5) \nu + W_{\mu}^{+} \ \overline{\nu} \ \gamma^{\mu} \ (1 - \gamma^5) e \right] \ . \tag{10.4}$$

For momenta small compared to M_W , this term gives rise to the effective four-fermion interaction with the Fermi constant given (at tree level, *i.e.*, lowest order in perturbation theory) by $G_F/\sqrt{2}=g^2/8M_W^2$. CP violation is incorporated in the Standard Model by a single observable phase in V_{ij} . The third term in \mathcal{L}_F describes electromagnetic interactions (QED), and the last is the weak neutral-current interaction.

In Eq. (10.1), m_i is the mass of the i^{th} fermion ψ_i . For the quarks these are the current masses. For the light quarks, as described in the Particle Listings, $m_u \approx 2\text{--}8$ MeV, $m_d \approx 5\text{--}15$ MeV, and $m_s \approx 100\text{--}300$ MeV (these are running masses evaluated at 1 GeV). For the heavier quarks, the "pole" masses are $m_c \approx 1.2\text{--}1.9$ GeV and $m_b \approx 4.5\text{--}4.9$ GeV. The average of the recent CDF [4] and DØ [5] values for m_t is 180 ± 12 GeV. See "The Note on Quark Masses" in the Particle Listings for more information.

H is the physical neutral Higgs scalar which is the only remaining part of ϕ after spontaneous symmetry breaking. The Yukawa coupling of H to ψ_i , which is flavor diagonal in the minimal model, is $gm_i/2M_W$. The H mass is not predicted by the model. Experimental limits are given in the Higgs section. In nonminimal models there are additional charged and neutral scalar Higgs particles [6].

10.1. Renormalization and radiative corrections

The Standard Model has three parameters (not counting M_H and the fermion masses and mixings). A particularly useful set is:

- (a) The fine structure constant α = 1/137.036, determined from the quantum Hall effect. In most electroweak-renormalization schemes, it is convenient to define a running α dependent on the energy scale of the process, with α⁻¹ ~ 137 appropriate at low energy. At energies of order M_Z, α⁻¹ ~ 128. For example, in the modified minimal subtraction (MS) scheme, one has α̂(M_Z)⁻¹ = 127.90 ± 0.09 [7], while the conventional (on-shell) QED renormalization yields [8] α(M_Z)⁻¹ = 128.90 ± 0.09, which differs by finite constants from α̂(M_Z)⁻¹. The uncertainty, due to the low-energy hadronic contribution to vacuum polarization, is the dominant theoretical uncertainty in the interpretation of precision data. The values include recent reevaluations [8-12] of this effect, which, following a correction to [11], are now in reasonable agreement. Further improvement will require improved measurements of the cross section for e⁺e⁻ → hadrons at low energy.
- (b) The Fermi constant, $G_F = 1.16639(2) \times 10^{-5} \text{ GeV}^{-2}$, determined from the muon lifetime formula [13]:

$$\tau_{\mu}^{-1} = \frac{G_F^2 m_{\mu}^5}{192\pi^3} F\left(\frac{m_e^2}{m_{\mu}^2}\right) \left(1 + \frac{3}{5} \frac{m_{\mu}^2}{M_W^2}\right) \times \left[1 + \frac{\alpha(m_{\mu})}{2\pi} \left(\frac{25}{4} - \pi^2\right)\right] , \qquad (10.5a)$$

where

$$F(x) = 1 - 8x + 8x^3 - x^4 - 12x^2 \ln x \tag{10.5b}$$

and

$$\alpha(m_{\mu})^{-1} = \alpha^{-1} - \frac{2}{3\pi} \ln\left(\frac{m_{\mu}}{m_{c}}\right) + \frac{1}{6\pi} \approx 136$$
. (10.5c)

The uncertainty in G_F from the input quantities is 1.1×10^{-10} GeV⁻². The quoted uncertainty of 2×10^{-10} is dominated by second order radiative corrections, estimated from the magnitude of the known $\alpha^2 \ln(m_\mu/m_e)$ term to be $\sim 1.8 \times 10^{-10}$ (alternately, one can view Eq. (10.5) as the exact definition of G_F ; then the theoretical uncertainty appears instead in the formulae for quantities derived from G_F).

(c) $\sin^2 \theta_W$, determined from the Z mass and other Z-pole observables, the W mass, and neutral-current processes [14]. The value of $\sin^2 \theta_W$ depends on the renormalization prescription. There are a number of popular schemes [16–21] leading to $\sin^2 \theta_W$ values which differ by small factors which depend on m_t and M_H . The notation for these schemes is shown in Table 10.1. Discussion of the schemes follows the table.

Table 10.1: Notations used to indicate the various schemes discussed in the text. Each definition of $\sin\theta_W$ leads to values that differ by small factors depending on m_t and M_H .

Scheme	Notation				
On-shell	$s_W = \sin \theta_W$				
NOV	$s_{M_Z} = \sin \theta_W$				
$\overline{\text{MS}}$	$\hat{s}_Z = \sin \theta_W$				
$\overline{ ext{MS}}$ ND	$\hat{s}_{ND} = \sin \theta_W$				
Effective angle	$\overline{s}_f = \sin \theta_W$				

(i) The on-shell scheme promotes the tree-level formula $\sin^2\theta_W=1-M_W^2/M_Z^2$ to a definition of the renormalized $\sin^2\theta_W$ to all orders in perturbation theory, i.e., $\sin^2\theta_W\to s_W^2\equiv 1-M_W^2/M_Z^2$. This scheme is simple conceptually. However, M_W is known much less precisely than M_Z and in practice one extracts s_W^2 from M_Z alone using

$$M_W = \frac{A_0}{s_W (1 - \Delta r)^{1/2}} \tag{10.6a}$$

$$M_Z = \frac{M_W}{c_W} \,, \tag{10.6b}$$

where $s_W \equiv \sin \theta_W$, $c_W \equiv \cos \theta_W$, $A_0 = (\pi \alpha/\sqrt{2}G_F)^{1/2} = 37.2802$ GeV, and Δr includes the radiative corrections relating α , $\alpha(M_Z)$, G_F , M_W , and M_Z . One finds $\Delta r \sim \Delta r_0 - \rho_t/\tan^2\theta_W$, where $\Delta r_0 \approx 1 - \alpha/\alpha(M_Z) \approx 0.06$ is due to the running of α and $\rho_t = 3G_F m_t^2/8\sqrt{2}\pi^2 \approx 0.0100$ $(m_t/180~{\rm GeV})^2$ represents the dominant (quadratic) m_t dependence. There are additional contributions to Δr from bosonic loops, including those which depend logarithmically on the Higgs mass M_H . One has $\Delta r = 0.0376 \pm 0.0025 \pm 0.0007$ for $(m_t, M_H) = (180 \pm 7, 300)$, where the second uncertainty is from $\alpha(M_Z)$. Thus the value of s_W^2 extracted from M_Z includes a large uncertainty (~ 0.0008) from the currently allowed range of m_t .

(ii) A more precisely determined quantity $s_{M_Z}^2$ can be obtained from M_Z by removing the (m_t, M_H) dependent term from Δr [17], i.e.,

$$s_{M_Z}^2 c_{M_Z}^2 \equiv \frac{\pi \alpha(M_Z)}{\sqrt{2} G_F M_Z^2}$$
 (10.7)

This yields $s_{MZ}^2=0.2311\pm0.0002$, with most of the uncertainty from α rather than M_Z . Scheme (ii) is equivalent to using M_Z rather than $\sin^2\theta_W$ as the third fundamental parameter. However, it recognizes that s_{MZ}^2 is still a useful derived quantity. The small uncertainty in s_{MZ}^2 compared to other schemes is because the m_t dependence has been removed by definition. However, the m_t uncertainty reemerges when other quantities $(e.g., M_W)$ or other Z-pole observables) are predicted in terms of M_Z .

Both s_W^2 and $s_{M_Z}^2$ depend not only on the gauge couplings but also on the spontaneous-symmetry breaking, and both definitions are awkward in the presence of any extension of the Standard Model which perturbs the value of M_Z (or M_W). Other definitions are motivated by the tree-level coupling constant definition $\theta_W = \tan^{-1}(g'/g)$.

(iii) In particular, the modified minimal subtraction $(\overline{\text{MS}})$ scheme introduces the quantity $\sin^2 \widehat{\theta}_W(\mu) \equiv \widehat{g}^{\prime 2}(\mu) / [\widehat{g}^{2}(\mu) +$ $\widehat{g}^{\prime 2}(\mu)$, where the couplings \widehat{g} and \widehat{g}' are defined by modified minimal subtraction and the scale μ is conveniently chosen to be M_Z for electroweak processes. The value of $\widehat{s}_Z^2 = \sin^2 \widehat{\theta}_W(M_Z)$ extracted from M_Z is less sensitive than s_W^2 to m_t (by a factor of $\tan^2\theta_W$), and is less sensitive to most types of new physics than s_W^2 or $s_{M_Z}^2$. It is also very useful for comparing with the predictions of grand unification. There are actually several variant definitions of $\sin^2 \widehat{\theta}_W(M_Z)$, differing according to whether or how finite $\alpha \ln(m_t/M_Z)$ terms are decoupled (subtracted from the couplings). One cannot entirely decouple the $\alpha \ln(m_t/M_Z)$ terms from all electroweak quantities because $m_t \gg m_b$ breaks SU(2) symmetry. The scheme that will be adopted here decouples the $\alpha \ln(m_t/M_Z)$ terms from the $\gamma - Z$ mixing [7,18], essentially eliminating any $\ln(m_t/M_Z)$ dependence in the formulae for asymmetries at the Z pole when written in terms of \hat{s}_{Z}^{2} . The various definitions are related by

$$\hat{s}_{Z}^{2} = c(m_{t}, M_{H}) s_{W}^{2} = \overline{c}(m_{t}, M_{H}) s_{M_{Z}}^{2},$$
 (10.8)

where $c=1.035\pm0.003$ for $m_t=180\pm7$ GeV and $M_H=300$ GeV. Similarly $\overline{c}=1.002\pm0.001$. The quadratic m_t dependence is given by $c\sim1+\rho_t/\tan^2\theta_W$. The expressions for M_W and M_Z in the $\overline{\rm MS}$ scheme are

$$M_W = \frac{A_0}{\hat{s}_Z (1 - \Delta \hat{r}_W)^{1/2}} \tag{10.9a}$$

$$M_Z = \frac{M_W}{\hat{\rho}^{1/2} \hat{c}_Z} \ . \tag{10.9b}$$

One predicts $\Delta \hat{r}_W = 0.0705 \pm 0.0001 \pm 0.0007$ for $m_t = 180 \pm 7$ GeV and $M_H = 300$ GeV. $\Delta \hat{r}_W$ has no quadratic m_t dependence, because shifts in M_W are absorbed into the observed G_F , so that $\Delta \hat{r}_W$ is dominated by $\Delta r_0 = 1 - \alpha/\alpha(M_Z)$. Similarly, $\hat{\rho} \sim 1 + \rho_t$. Including bosonic loops, $\hat{\rho} = 0.0103 \pm 0.0008$ for $m_t = 180 \pm 7$ GeV.

(iv) A variant $\overline{\rm MS}$ quantity $\widehat{s}_{\rm ND}^2$ (used in the 1992 edition of this Review) does not decouple the $\alpha \ln(m_t/M_Z)$ terms [19]. It is related to \widehat{s}_Z^2 by

$$\widehat{s}_Z^2 = \widehat{s}_{ND}^2 / \left(1 + \frac{\widehat{\alpha}}{\pi} d \right) \tag{10.10a}$$

$$d = \frac{1}{3} \left(\frac{1}{\widehat{s}^2} - \frac{8}{3} \right) \left[\left(1 + \frac{\widehat{\alpha}_s}{\pi} \right) \ln \frac{m_t}{M_Z} - \frac{15\widehat{\alpha}_s}{\pi} \right] , \quad (10.10b)$$

where $\widehat{\alpha}_s$ is the QCD coupling at M_Z . Thus, $\widehat{s}_Z^2 - \widehat{s}_{\rm ND}^2 \sim -0.0002$ for $(m_t, M_H) = (180, 300)$ GeV.

(v) Yet another definition, the effective angle [20,21] \overline{s}_f^2 for Z coupling to fermion f, is described below.

Experiments are now at such a level of precision that complete $\mathcal{O}(\alpha)$ radiative corrections must be applied. For neutral-current and Z-pole processes, these corrections are conveniently divided into two classes:

- 1. QED diagrams involving the emission of real photons or the exchange of virtual photons in loops, but not including vacuum polarization diagrams. These graphs yield finite and gauge-invariant contributions to observable processes. However, they are dependent on energies, experimental cuts, etc., and must be calculated individually for each experiment.
- 2. Electroweak corrections, including $\gamma\gamma$, γZ , ZZ, and WW vacuum polarization diagrams, as well as vertex corrections, box graphs, etc., involving virtual W's and Z's. Many of these corrections are absorbed into the renormalized Fermi constant defined in Eq. (10.5). Others modify the tree-level expressions for Z-pole observables and neutral-current amplitudes in several ways [14]. One-loop corrections are included for all processes. In addition, certain two-loop corrections are also important. In particular, two-loop corrections involving the top-quark [22] modify ρ_t in $\hat{\rho}$, Δr , and elsewhere by

$$\rho_t \to \rho_t [1 + R(M_H/m_t)\rho_t/3] ,$$
(10.11)

where -3.8 > R > -11.8 is strongly dependent on M_H/m_t : R = -3.8 for M_H at its lower direct limit and R = -7.8 for $M_H = 1.7m_t \approx 300$ GeV. -11.8 is in absolute lower bound for R which is assumed for large M_H . Mixed QCD-electroweak loops of order $\alpha \alpha_s m_t^2$ [23] and $\alpha \alpha_s^2 m_t^2$ [24] multiply ρ_t by 1-2 $\alpha_s(0.3m_t)(\pi^2+3)/9\pi \sim 0.88$, where the three-loop result is included through the use of a lower scale for α_s . These mixed corrections increase the predicted value of m_t by 6%. Analogous electroweak and mixed two-loop terms are also known for the $Z \to b\bar{b}$ vertex [22,25].

10.2. Cross section and asymmetry formulas

It is convenient to write the four-fermion interactions relevant to ν -hadron, νe , and parity-violating e-hadron neutral-current processes in a form that is valid in an arbitrary gauge theory (assuming massless left-handed neutrinos). One has

$$-\mathcal{L}^{\nu \text{Hadron}} = \frac{G_F}{\sqrt{2}} \, \overline{\nu} \, \gamma^{\mu} \, (1 - \gamma^5) \nu$$

$$\times \sum_{i} \left[\epsilon_L(i) \, \overline{q}_i \, \gamma_{\mu} (1 - \gamma^5) q_i + \epsilon_R(i) \, \overline{q}_i \, \gamma_{\mu} (1 + \gamma^5) q_i \right] , \quad (10.12)$$

$$-\mathcal{L}^{\nu e} = \frac{G_F}{\sqrt{2}} \, \overline{\nu}_{\mu} \, \gamma^{\mu} (1 - \gamma^5) \nu_{\mu} \, \overline{e} \, \gamma_{\mu} (g_V^{\nu e} - g_A^{\nu e} \gamma^5) e \quad (10.13)$$

(for $\nu_e e$ or $\overline{\nu}_e e$, the charged-current contribution must be included), and

$$-\mathscr{L}^{e \text{Hadron}} = -\frac{G_F}{\sqrt{2}}$$

$$\times \sum_{i} \left[C_{1i} \ \overline{e} \ \gamma_{\mu} \ \gamma^5 \ e \ \overline{q}_i \ \gamma^{\mu} \ q_i + C_{2i} \ \overline{e} \ \gamma_{\mu} \ e \ \overline{q}_i \ \gamma^{\mu} \ \gamma^5 \ q_i \right] (10.14)$$

(One must add the parity-conserving QED contribution.)

The Standard Model expressions for $\epsilon_{L,R}(i)$, $g_{V,A}^{\nu e}$, and C_{ij} are given in Table 10.2. Note that $g_{V,A}^{\nu e}$ and the other quantities are coefficients of effective four-fermi operators, which differ from the quantities defined in Eq. (10.2) and Eq. (10.3) in the radiative corrections and in the presence of possible physics beyond the Standard Model.

A precise determination of the on-shell s_W^2 , which depends only very weakly on m_t and M_H , is obtained from deep inelastic neutrino scattering from (approximately) isoscalar targets [26]. The ratio $R_{\nu} \equiv \sigma_{\nu N}^{NC}/\sigma_{\nu N}^{CC}$ of neutral- to charged-current cross sections has been measured to 1% accuracy by the CDHS [27] and CHARM [28] collaborations [29,30] at CERN, and the CCFR collaboration at Fermilab [31] has obtained an even more precise result, so it is important to obtain theoretical expressions for R_{ν} and $R_{\overline{\nu}} \equiv \sigma_{\overline{\nu}N}^{NC}/\sigma_{\overline{\nu}N}^{CC}$ (as functions of $\sin^2\theta_W$) to comparable accuracy. Fortunately, most of the uncertainties from the strong interactions and neutrino spectra cancel in the ratio.

A simple zero th -order approximation is

$$R_{\nu} = g_L^2 + g_R^2 r \tag{10.15a}$$

$$R_{\overline{\nu}} = g_L^2 + \frac{g_R^2}{r} \,,$$
 (10.15b)

where

$$g_L^2 \equiv \epsilon_L (u)^2 + \epsilon_L (d)^2 \approx \frac{1}{2} - \sin^2 \theta_W + \frac{5}{9} \sin^4 \theta_W$$
 (10.16a)

$$g_R^2 \equiv \epsilon_R (u)^2 + \epsilon_R (d)^2 \approx \frac{5}{9} \sin^4 \theta_W , \qquad (10.16b)$$

and $r \equiv \sigma^{CC}_{\overline{\nu}N}/\sigma^{CC}_{\nu N}$ is the ratio of $\overline{\nu}$ and ν charged-current cross sections, which can be measured directly. [In the simple parton model, ignoring hadron energy cuts, $r \approx (\frac{1}{3} + \epsilon)/(1 + \frac{1}{3}\epsilon)$, where $\epsilon \sim 0.125$ is the ratio of the fraction of the nucleon's momentum carried by antiquarks to that carried by quarks.] In practice, Eq. (10.15) must be corrected for quark mixing, the s and c seas, c-quark threshold effects, nonisoscalar target effects, W-Z propagator differences, and radiative corrections (which lower the extracted value of $\sin^2 \theta_W$ by ~ 0.009). Details of the neutrino spectra, experimental cuts, x and Q^2 dependence of structure functions, and longitudinal structure functions enter only at the level of these corrections and therefore lead to very small uncertainties. The largest theoretical uncertainty is associated with the c threshold, which mainly affects σ^{CC} . Using the slow rescaling prescription [14]—the central value of $\sin^2 \theta_W$ varies as 0.013 $[m_c(\text{GeV})-1.3]$, where m_c is the effective mass. For $m_c = 1.31 \pm 0.24$ GeV (determined from ν -induced dimuon production [31]) this contributes ± 0.003 to the total theoretical

Table 10.2: Standard Model expressions for the neutral-current parameters for ν -hadron, νe , and e-hadron processes. If radiative corrections are ignored, $\rho=\kappa=1,\ \lambda=0.$ At $\mathcal{O}(\alpha)$ in the on-shell scheme, $\rho_{\nu N}^{NC}=1.0095,\ \kappa_{\nu N}=1.0382,\ \lambda_{u_L}=-0.0032,\ \lambda_{d_L}=-0.0026,\ \mathrm{and}\ \lambda_{u_R}=1/2\ \lambda_{d_R}=3.6\times 10^{-5}$ for $m_t=180$ GeV, $M_H=300$ GeV, $M_Z=91.1884$ GeV, and $\langle Q^2\rangle=20$ GeV². For νe scattering, $\kappa_{\nu e}=1.0385$ and $\rho_{\nu e}=1.0143$ (at $\langle Q^2\rangle=0.$). For atomic parity violation, $\rho_{eq}'=0.9884$ and $\kappa_{eq}'=1.036.$ For the SLAC polarized electron experiment, $\rho_{eq}'=0.979,\ \kappa_{eq}'=1.034,\ \rho_{eq}=1.002,\ \mathrm{and}\ \kappa_{eq}=1.06$ after incorporating additional QED corrections, while $\lambda_{2u}=-0.013,\ \lambda_{2d}=0.003.$ The dominant m_t dependence is given by $\rho\sim1+\rho_t,$ while $\kappa\sim1+\rho_t/\tan^2\theta_W$ (on-shell) or $\kappa\sim1(\overline{\mathrm{MS}}).$

Quantity	Standard Model Expression
$\epsilon_L(u)$	$\rho_{\nu N}^{NC} \left(\frac{1}{2} - \frac{2}{3} \kappa_{\nu N} \sin^2 \theta_W + \lambda_{uL} \right)$
$\epsilon_L(d)$	$ ho_{ u N}^{NC} \left(-rac{1}{2} + rac{1}{3} \kappa_{ u N} \sin^2 heta_W + \lambda_{dL} ight)$
$\epsilon_R(u)$	$ ho_{ u N}^{NC} \left(-rac{2}{3} \kappa_{ u N} \sin^2 heta_W + \lambda_{uR} ight)$
$\epsilon_R(d)$	$ ho_{ u N}^{NC} \left(rac{1}{3} \kappa_{ u N} \sin^2 heta_W + \lambda_{dR} ight)$
$g_V^{ u e} \ g_A^{ u e}$	$\rho_{\nu e} \left(-\frac{1}{2} + 2\kappa_{\nu e} \sin^2 \theta_W \right)$ $\rho_{\nu e} \left(-\frac{1}{2} \right)$
C_{1u}	$\rho'_{eq}\left(-\frac{1}{2} + \frac{4}{3}\kappa'_{eq}\sin^2\theta_W\right)$
C_{1d}	$\rho_{eq}'\left(\frac{1}{2} - \frac{2}{3}\kappa_{eq}'\sin^2\theta_W\right)$
C_{2u}	$\rho_{eq} \left(-\frac{1}{2} + 2\kappa_{eq} \sin^2 \theta_W \right) + \lambda_{2u}$
C_{2d}	$\rho_{eq} \left(\frac{1}{2} - 2\kappa_{eq} \sin^2 \theta_W \right) + \lambda_{2d}$

uncertainty $\Delta \sin^2 \theta_W \sim \pm 0.004$. This would require a high-energy neutrino beam for improvement. (The experimental uncertainty is ± 0.003). The CCFR group quotes $s_W^2 = 0.2218 \pm 0.0059$ for $(m_t, M_H) = (150, 100)$, but this result is insensitive to (m_t, M_H) . Combining all of the precise deep-inelastic measurements, one obtains $s_W^2 = 0.2259 \pm 0.0043$ for (m_t, M_H) in the allowed range.

The laboratory cross section for $\nu_{\mu}e \to \nu_{\mu}e$ or $\overline{\nu}_{\mu}e \to \overline{\nu}_{\mu}e$ elastic scattering is

$$\frac{d\sigma_{\nu_{\mu},\overline{\nu}_{\mu}}}{dy} = \frac{G_F^2 m_e E_{\nu}}{2\pi}
\times \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + (g_V^{\nu e} \mp g_A^{\nu e})^2 (1 - y)^2 \right]
- (g_V^{\nu e 2} - g_A^{\nu e 2}) \frac{y m_e}{E_{\nu}} ,$$
(10.17)

where the upper (lower) sign refers to $\nu_{\mu}(\overline{\nu}_{\mu})$, and $y \equiv E_e/E_{\nu}$ [which runs from 0 to $(1+m_e/2E_{\nu})^{-1}$] is the ratio of the kinetic energy of the recoil electron to the incident ν or $\overline{\nu}$ energy. For $E_{\nu} \gg m_e$ this yields a total cross section

$$\sigma = \frac{G_F^2 \ m_e \ E_{\nu}}{2\pi} \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + \frac{1}{3} (g_V^{\nu e} \mp g_A^{\nu e})^2 \right] \ . \tag{10.18}$$

The most accurate leptonic measurements [32–34] of $\sin^2\theta_W$ are from the ratio $R \equiv \sigma_{\nu_\mu e}/\sigma_{\overline{\nu}_\mu e}$ in which many of the systematic uncertainties cancel. Radiative corrections (other than m_t effects) are small compared to the precision of present experiments and have negligible effect on the extracted $\sin^2\theta_W$. The most precise (CHARM II) experiment [34] determined not only $\sin^2\theta_W$ but $g_{V,A}^{\nu e}$ as well. The cross sections for $\nu_e e$ and $\overline{\nu}_e e$ may be obtained from

Eq. (10.17) by replacing $g_{V,A}^{\nu e}$ by $g_{V,A}^{\nu e}+1$, where the 1 is due to the charged-current contribution.

The SLAC polarized-electron experiment [35] measured the parity-violating asymmetry

$$A = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L} , \qquad (10.19)$$

where $\sigma_{R,L}$ is the cross section for the deep-inelastic scattering of a right- or left-handed electron: $e_{R,L}N \to eX$. In the quark parton model

$$\frac{A}{Q^2} = a_1 + a_2 \, \frac{1 - (1 - y)^2}{1 + (1 - y)^2} \,, \tag{10.20}$$

where $Q^2 > 0$ is the momentum transfer and y is the fractional energy transfer from the electron to the hadrons. For the deuteron or other isoscalar target, one has, neglecting the s quark and antiquarks,

$$a_1 = \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(C_{1u} - \frac{1}{2}C_{1d} \right) \approx \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(-\frac{3}{4} + \frac{5}{3}\sin^2\theta_W \right) (10.21a)$$

$$a_2 = \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(C_{2u} - \frac{1}{2}C_{2d}\right) \approx \frac{9G_F}{5\sqrt{2}\pi\alpha} \left(\sin^2\theta_W - \frac{1}{4}\right) \ . \ \ (10.21b)$$

Radiative corrections (other than m_t effects) lower the extracted value of $\sin^2 \theta_W$ by $\sim~0.005$.

There are now precise experiments measuring atomic parity violation [36] in cesium [37], bismuth [38], lead [39], and thallium [40]. The uncertainties associated with atomic wave functions are quite small for cesium, for which the theoretical uncertainty is $\sim 1\%$ [41] but somewhat larger for the other atoms. For heavy atoms one determines the "weak charge"

$$Q_W = -2 \left[C_{1u} \left(2Z + N \right) + C_{1d} (Z + 2N) \right]$$

$$\approx Z (1 - 4 \sin^2 \theta_W) - N . \tag{10.22}$$

Radiative corrections increase the extracted $\sin^2 \theta_W$ by ~ 0.008 .

In the future it should be possible to reduce the theoretical wave function uncertainties by taking the ratios of parity violation in different isotopes [36,42]. There would still be some residual uncertainties from differences in the neutron charge radii, however [43].

The forward-backward asymmetry for $e^+e^- \to \ell \bar{\ell}$, $\ell = \mu$ or τ , is defined as

$$A_{FB} \equiv \frac{\sigma_F - \sigma_B}{\sigma_F + \sigma_B} \,\,, \tag{10.23}$$

where $\sigma_F(\sigma_B)$ is the cross section for ℓ^- to travel forward (backward) with respect to the e^- direction. A_{FB} and R, the total cross section relative to pure QED, are given by

$$R = F_1 \tag{10.24}$$

$$A_{FB} = 3F_2/4F_1 , (10.25)$$

where

$$F_1 = 1 - 2\chi_0 g_V^e g_V^\ell \cos \delta_R + \chi_0^2 \left(g_V^{e2} + g_A^{e2} \right) \left(g_V^{\ell2} + g_A^{\ell2} \right) \quad (10.26a)$$

$$F_2 = -2\chi_0 g_A^e g_A^\ell \cos \delta_R + 4\chi_0^2 g_A^e g_A^\ell g_V^\ell g_V^\ell , \qquad (10.26b)$$

where

$$\tan \delta_R = \frac{M_Z \Gamma_Z}{M_Z^2 - s} \tag{10.27}$$

$$\chi_0 = \frac{G_F}{2\sqrt{2}\pi\alpha} \frac{sM_Z^2}{\left[(M_Z^2 - s)^2 + M_Z^2\Gamma_Z^2\right]^{1/2}}$$
(10.28)

and \sqrt{s} is the CM energy. Eq. (10.26) is valid at tree level. If the data are radiatively corrected for QED effects (as described above),

then the remaining electroweak corrections can be incorporated [44] (in an approximation adequate for existing PEP, PETRA, and TRISTAN data, which are well below the Z pole) by replacing χ_0 by $\chi(s) \equiv (1+\rho_t)\chi_0(s)\alpha/\alpha(s)$, where $\alpha(s)$ is the running QED coupling, and evaluating g_V in the $\overline{\text{MS}}$ scheme. Formulas for $e^+e^- \to hadrons$ may be found in Ref. 45.

At LEP and SLC, there are high-precision measurements of various Z-pole observables [46–49]. These include the Z mass and total width Γ_{Z} , and partial widths $\Gamma(f\overline{f})$ for $Z \to f\overline{f}$ for fermion f ($f=e,\mu,\tau$, hadrons, b,c, and ν). The data is consistent with lepton-family universality $\Gamma(e^+e^-) = \Gamma(\mu^+\mu^-) = \Gamma(\tau^+\tau^-)$, so one may work with an average width $\Gamma(\ell\overline{\ell})$. It is convenient to use the variables M_Z , Γ_Z , $R \equiv \Gamma(\mathrm{had})/\Gamma(\ell\overline{\ell})$, $\sigma_{\mathrm{had}} \equiv 12\pi\Gamma(e^+e^-)\Gamma(\mathrm{had})/M_Z^2\Gamma_Z^2$, $R_b \equiv \Gamma(b\overline{b})/\Gamma(\mathrm{had})$, and $R_c \equiv \Gamma(c\overline{c})/\Gamma(\mathrm{had})$, most of which are weakly correlated experimentally. ($\Gamma(\mathrm{had})$ is the partial width into hadrons.) The largest correlation coefficient of -0.35 occurs between R_b and R_c . R is insensitive to m_t except for $Z \to b\overline{b}$ vertex and final state corrections and the implicit dependence through $\sin^2\theta_W$. Thus it is especially useful for constraining α_s . The width for invisible decays, $\Gamma(\mathrm{inv}) = \Gamma_Z - 3\Gamma(\ell\overline{\ell}) - \Gamma(\mathrm{had}) = 499.9 \pm 2.5$ MeV, can be used to determine the number of neutrino flavors lighter than $M_Z/2$, $N_{\nu} = \Gamma_{\mathrm{inv}}/\Gamma(\nu\overline{\nu}) = 2.991 \pm 0.016$.

There are also measurements of various asymmetries. These include the polarization or left-right asymmetry

$$A_{LR} \equiv \frac{\sigma_L - \sigma_R}{\sigma_L + \sigma_R} \; , \tag{10.29}$$

where $\sigma_L(\sigma_R)$ is the cross section for a left- (right)-handed incident electron. A_{LR} has been measured precisely by the SLD collaboration at SLC [48] and has the advantages of being extremely sensitive to $\sin^2\theta_W$ and insensitive to QED radiative corrections. Other asymmetries are the forward-backward asymmetries $A_{FB}^{(0,f)}$ for f=e, $\mu,$ $\tau,$ b, c $(A_{FB}^{(0,e)}, A_{FB}^{(0,\mu)}, A_{FB}^{(0,\tau)}$ are consistent with lepton-family universality, allowing an average value $A_{FB}^{(0,\ell)}$), the hadronic-charge asymmetry, the τ polarization P_{τ} , and its angular distribution. Further details, including references to the data from the LEP experiments (ALEPH, DELPHI, L3, OPAL) may be found in the Particle Listings in the 'Note on the Z Boson' and in [46–49]. At tree level and neglecting QED effects and terms of order $(\Gamma_Z/M_Z)^2$, one has

$$A_{FB}^{(0,f)} \approx \frac{3}{4} A_f \frac{A_e + P_e}{1 + P_e A_e}$$
 (10.30)

$$A_{LR} \approx A_e P_e \ , \tag{10.31}$$

where P_e is the initial e^- polarization and

$$A_f \equiv \frac{2g_V^f g_A^f}{g_V^{f2} + g_A^{f2}} \ . \tag{10.32}$$

Similarly, A_{τ} is given by the negative total τ polarization, and A_{e} can be extracted from the angular distribution of the polarization. In addition, the SLD collaboration [49] has extracted the final-state couplings A_{b} and A_{c} from the left-right forward-backward asymmetry, using

$$\frac{\sigma_{LF} - \sigma_{LB} - \sigma_{RF} + \sigma_{RB}}{\sigma_{LF} + \sigma_{LB} + \sigma_{RF} + \sigma_{RB}} = A_f , \qquad (10.33)$$

where, for example, σ_{LF} is the cross section for a left-handed incident electron to produce a fermion f traveling in the forward hemisphere.

It has become customary for the experimental groups to present corrected asymmetries A^0 , in which photon exchange and γ -Z interference, QED corrections, and corrections for $\sqrt{s} \neq M_Z$ are removed from the data, leaving the pure electroweak asymmetries. Ignoring negligible electroweak boxes, these corrected asymmetries are expressed using effective tree-level expression e.g., $A_{FB}^{(0,f)} = \frac{3}{4}\overline{A}_f\overline{A}_e$ (for $P_e=0$) and $A_{LR}^0 = \overline{A}_e$, where

$$\overline{A}_f = \frac{2\overline{g}_V^f \, \overline{g}_A^f}{\overline{g}_V^{f2} + \overline{g}_A^{f2}} \,, \tag{10.34a}$$

and

$$\overline{g}_V^f = \sqrt{\rho_f} \left(t_{3L}^{(f)} - 2q_f \kappa_f \sin^2 \theta_W \right) \tag{10.34b}$$

$$\overline{g}_A^f = \sqrt{\rho_f} \, t_{3L}^{(f)} \,. \tag{10.34c}$$

The electroweak-radiative corrections have been absorbed into corrections ρ_f-1 and κ_f-1 , which depend on the fermion f and on the renormalization scheme. In the on-shell scheme, the quadratic m_t dependence is given by $\rho_f\sim 1+\rho_t,\,\kappa_f\sim\kappa_f^{os}\sim 1+\rho_t/\tan^2\theta_W,$ while in $\overline{\rm MS},\,\rho_f\sim\widehat{\rho},\,\kappa_f\equiv\widehat{\kappa}_f\sim 1.$ In practice, additional bosonic loops, vertex corrections, etc., must be included. For example, in the $\overline{\rm MS}$ scheme one has, for $(m_t,M_H)=(180,300),\,\rho_\ell=1.0053$ and $\widehat{\kappa}_\ell=1.0012.$ It is convenient to define an effective angle $\overline{s}_f^2\equiv\sin^2\overline{\theta}_{Wf}\equiv\widehat{\kappa}_f\widehat{s}_Z^2=\kappa_f^{os}\,s_W^2$, in terms of which \overline{g}_V^f and \overline{g}_A^f are given by $\sqrt{\rho_f}$ times their tree-level formulae. Because \overline{g}_V^ℓ is very small, not only A_{LR}^0 $A_{FB}^{(0,\ell)}$, and P_τ^0 , but also $A_{FB}^{(0,b)}$, $A_{FB}^{(0,c)}$, and the hadronic-charge asymmetry are mainly sensitive to \overline{s}_ℓ^2 . One finds that $\widehat{\kappa}_f$ is almost independent of (m_t,M_H) , so that

$$\bar{s}_{\ell}^2 \sim \hat{s}_{Z}^2 + 0.00028$$
 (10.35)

using Ref. 20, or $\overline{s}_\ell^2 \sim \widehat{s}_Z^2 + 0.0002$ from Ref. 21 (the small difference is an indication of theoretical uncertainties from higher-order terms, etc.). In any case, the asymmetries determine values of \overline{s}_ℓ^2 and \widehat{s}_Z^2 almost independent of m_t , while the κ 's for the other schemes are m_t dependent.

10.3. W and Z decays

The partial decay width for gauge bosons to decay into massless fermions $f_1 \overline{f}_2$ is

$$\Gamma(W^+ \to e^+ \nu_e) = \frac{G_F M_W^3}{6\sqrt{2}\pi} \approx 226 \pm 1 \text{ MeV}$$
 (10.36a)

$$\Gamma(W^+ \to u_i \overline{d}_j) = \frac{CG_F M_W^3}{6\sqrt{2}\pi} |V_{ij}|^2 \approx (705 \pm 4) |V_{ij}|^2 \text{ MeV} \quad (10.36b)$$

$$\Gamma(Z \to \psi_i \overline{\psi}_i) = \frac{C G_F M_Z^3}{6\sqrt{2}\pi} \left[g_V^{i2} + g_A^{i2} \right]$$
 (10.36c)

$$\approx \begin{cases} 167.2 \pm 0.1 \text{ MeV } (\nu \overline{\nu}), & 84.0 \pm 0.1 \text{ MeV } (e^+e^-), \\ 300.6 \pm 0.3 \text{ MeV } (u\overline{u}), & 383.3 \pm 0.3 \text{ MeV } (d\overline{d}), \\ 375.9 \mp 0.2 \text{ MeV } (b\overline{b}). \end{cases}$$

For leptons C=1, while for quarks $C=3\Big(1+\alpha_s(M_V)/\pi+1.409\alpha_s^2/\pi^2\Big)$ $-12.77\alpha_s^3/\pi^3$), where the 3 is due to color and the factor in parentheses represents the universal QCD corrections for massless quarks [50]. The $Z \to f\overline{f}$ widths contain a number of additional corrections [51]: universal (non-singlet) top-mass contributions [52]; fermion mass effects and further QCD corrections proportional to m_q^2 [53] (m_q is the running quark mass evaluated at the Z scale) which are different for vector and axial-vector partial widths; and singlet contributions starting from two loop order which are large, strongly top-mass dependent, family universal and flavor non-universal [54]. All QCD effects are known and included up to three loop order with the exception of order $\alpha_s^3 m_b^2$ corrections which are very small. The QED factor $1 + 3\alpha q_f^2/4\pi$ and order $\alpha\alpha_s$ corrections [55] have to be included, as well. Expressing the widths in terms of $G_F M_{W,Z}^3$ incorporates the bulk of the low-energy radiative corrections [16,56] The electroweak corrections are incorporated by replacing $g_{V,A}^{i2}$ by $\overline{g}_{V,A}^{i2}$. Hence, the widths are proportional to $\rho_i \sim 1 + \rho_t$. There is additional (negative) quadratic m_t dependence in the $Z \to b\bar{b}$ vertex corrections [57] which causes $\Gamma(b\bar{b})$ to decrease with m_t . The dominant effect is to multiply $\Gamma(b\bar{b})$ by the vertex correction $1 + \delta \rho_{b\bar{b}}$, where

 $\delta \rho_{b\overline{b}} \sim 10^{-2} (-rac{1}{2} rac{m_t^2}{M_Z^2} + rac{1}{5})$. In practice, the corrections are included in ho_b and κ_b .

For 3 fermion families the total widths are predicted to be

$$\Gamma_Z \approx 2.497 \pm 0.002 \text{ GeV}$$
 (10.37)

$$\Gamma_W \approx 2.09 \pm 0.01 \text{ GeV}$$
 (10.38)

The numerical values for the widths assume $M_Z=91.1884\pm0.0022$ GeV, $M_W=80.26\pm0.16$ GeV, $\alpha_s=0.123$, and $m_t=180\pm7$ GeV, where the α_s and m_t values are predicted by the global fits for $M_H=300$ GeV. The uncertainties for Γ_W and Γ_Z are dominated by ΔM_W and Δm_t , respectively. The uncertainty in α_s , ±0.004 , introduces an additional uncertainty of 0.13% in the hadronic widths, corresponding to ±2 MeV in Γ_Z .

These predictions are to be compared with the experimental results $\Gamma_Z=2.4963\pm0.0032$ GeV and $\Gamma_W=2.08\pm0.07$ GeV.

10.4. Experimental results

The values of the principal Z-pole observables are listed in Table 10.3, along with the Standard Model predictions for M_Z = 91.1884 ± 0.0022 , $m_t = 180 \pm 7 \text{ GeV}$ (for $M_H = 300 \text{ GeV}$), 60 GeV $< M_H < 1$ TeV, and $\alpha_s = 0.123 \pm 0.004$. Note that, the values of the Z-pole observables (as well as M_W) differ from those in the Particle Listings because they include recent preliminary results [47,49,59]. The values and predictions of M_W [59], the Q_W for cesium [36,41], and recent results from deep inelastic and $\nu_{\mu}e$ scattering are also listed. The agreement is generally excellent. Major exceptions are $R_b = \Gamma(b\bar{b})/\Gamma(\text{had})$ which is 3.7 σ above the Standard Model prediction, and $R_c = \Gamma(c\overline{c})/\Gamma(\text{had})$ which is 2.4σ below. These are strongly correlated: if R_c is fixed at the Standard Model value of 0.172, then one obtains [47] $R_b = 0.2205 \pm 0.0016$, which is still 3.0σ too high. Within the Standard Model framework, these values must be considered large statistical fluctuations or systematic errors. However, R_b tends to favor small values of m_t , and when combined with other observables, small values for M_H . Many types of new physics could contribute to R_b (see also Sec. 14 on "Constraints on New Physics from Electroweak Analyses" in this Review). The implications of this possiblity for the value of $\alpha_s(M_Z)$ extracted from the fits are discussed below. The left-right asymmetry $A_{LR}^0=0.1551\pm0.0040$ [49] based on all data from 1992–1995 has moved closer to the Standard Model expectation of 0.144 ± 0.003 than the previous value 0.1637 ± 0.0075 , from 1992–1993. However, because of the smaller error A_{LR}^0 is still 2.3σ above the Standard Model prediction. There is also an experimental difference of $\sim 1.5\sigma$ between the SLD value of $A_e^0=A_{LR}^0$ and the LEP value $A_{\ell \rm LEP}^0 \sim 0.147 \pm 0.004$ obtained from $A_{FB}^{(0,\ell)}$, $A_e^0(P_\tau)$, $A_\tau^0(P_\tau)$ assuming lepton family universality. Finally, the forward-backward asymmetry into τ 's, $A_{FB}^{0\tau}=0.0206\pm0.0023$ [47], is 2.2σ above the Standard Model prediction and 1.6σ above the average 0.0162 ± 0.0014 of A_{FB}^{0e} and $A_{FB}^{0\mu}$. This is small enough to be a fluctuation, so lepton-family universality will be assumed. The observables in Table 10.3 (including correlations on the LEP observables), as well as all low-energy neutral-current data [14,15], are used in the global fits described below. The parameter $\sin^2 \theta_W$ can be determined from the Z-pole observables and M_W , and from a variety of neutral-current processes spanning a very wide Q^2 range. The results [14], shown in Table 10.4, are in impressive agreement with each other, indicating the quantitative success of the Standard Model. The one discrepancy is the value $\hat{s}_Z^2 = 0.2302 \pm 0.0005$ from A_{LR}^0 which is 2.1σ below the value (0.2315 $\stackrel{\sim}{\pm}$ 0.0004) from the global fit to all data and 2.6 σ below the value 0.2318 \pm 0.0004 obtained from all data other than A_{LR}^0 .

The data allow a simultaneous determination of $\sin^2\theta_W$, m_t , and the strong coupling $\alpha_s(M_Z)$. The latter is determined mainly from Γ_Z and R, and is only weaky correlated with the other variables. The global fit to all data, including the CDF/DØ value $m_t=180\pm12$ GeV, yields

$$\begin{split} \widehat{s}_Z^2 &= 0.2315 \pm 0.0002 \pm 0.0003 \\ m_t &= 180 \pm 7^{+12}_{-13} \text{ GeV} \\ \alpha_s(M_Z) &= 0.123 \pm 0.004 \pm 0.002 \;, \end{split} \tag{10.39}$$

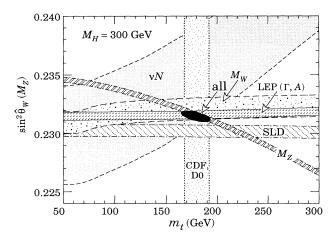

Figure 10.1: One-standard-deviation uncertainties in $\sin^2 \hat{\theta}_W$ as a function of m_t , the direct CDF and DØ range 180 ± 12 GeV, and the 90% CL region in $\sin^2 \hat{\theta}_W - m_t$ allowed by all data, assuming $M_H = 300$ GeV.

where the central values are for a Higgs mass of 300 GeV, and the second error bars are for $M_H \rightarrow 1000(+)$ or 60(-) GeV. In all fits, the errors include full statistical, systematic, and theoretical uncertainties. The \hat{s}_Z^2 error is dominated by m_t , and \hat{s}_Z^2 and m_t have a strong negative correlation of ~ -0.62 . In the on-shell scheme one has $s_W^2 = 0.2236 \pm 0.0008$, the larger error due to the stronger sensitivity to m_t . The extracted value of α_s is based on a formula which has almost no theoretical uncertainty (if one assumes the exact validity of the Standard Model), and is in excellent agreement with the values 0.122 ± 0.007 from jet-event shapes in e^+e^- annihilation, and the average 0.118 ± 0.003 from all data (including the Z-lineshape data), as described in our Section 9 on "Quantum Chromodynamics" in this Review. However, it is higher than some of the individual values extracted from low-energy data, such as deep-inelastic scattering $(0.112 \pm 0.002 ~({\rm exp}) \pm 0.004 ~({\rm scale}))$ or lattice calculations of the $b\bar{b}$ and $c\overline{c}$ spectra (0.115 \pm 0.003). It has been suggested [60] that there is a real discrepancy. However, caution is required since most of the determinations are dominated by theory errors.

The value of R_b is more than 3σ above the Standard Model expectation. If this is not just a fluctuation but is due to a new physics contribution to the $Z \to b\bar{b}$ vertex (many types would couple preferentially to the third family), the value of $\alpha_s(M_Z)$ extracted from the hadronic Z width would be reduced [15]. Allowing for this possibility one obtains $\alpha_s(M_Z) = 0.101 \pm 0.008$. (See also Sec. 14 on "Constraints on New Physics from Electroweak Analyses." in this Review

In principle the low value of R_c could also be due to new physics. However, allowing for new physics contributions to R_c alone, one obtains $\alpha_s(M_Z)=0.19\pm0.03$, which is clearly inconsistent with low-energy determinations. Allowing new contributions to both R_b and R_c yields the slightly lower but still high value of $\alpha_s(M_Z)=0.16\pm0.04$. We will, therefore, take the view that the R_c value is a fluctuation. We keep the experimental values $R_b=0.2219(17)$ and $R_c=0.1540(74)$ and their correlation (-0.35) in all fits, but do not allow any special vertex corrections for $Z\to c\overline{c}$. This is effectively equivalent to using the lower value 0.2205(16) that the LEP experimenters obtain for R_b when they constrain R_c to the Standard Model value of 0.172.

One can also carry out a fit to the indirect data alone, i.e., without including the value $m_t=180\pm12$ GeV observed directly by CDF and DØ. (The indirect prediction is for the pole mass, which should correspond approximately to the kinematic mass extracted from the collider events.) One obtains $m_t=179\pm8^{+17}_{-20}$ GeV, with little change in the $\sin^2\theta_W$ and α_s values, in remarkable agreement with the direct CDF/DØ value. The results of fits to various combinations of the data are shown in Table 10.5 and the relation between \hat{s}_Z^2 and m_t for various observables in Fig. 10.1.

The data indicate a preference for a small Higgs mass. This is because there is a strong correlation between the quadratic ρ_t terms and logarithmic M_H effects in all of the indirect data except the $Z o b\overline{b}$ vertex. The latter favor a smaller m_t and therefore a smaller M_H . The difference in χ^2 for the global fit is $\Delta \chi^2 = \chi^2(M_H = 1000 \text{ GeV}) - \chi^2(M_H = 60 \text{ GeV}) = 7.9$. Hence, the data favor a small value of M_H , as in supersymmetric extensions of the Standard Model, and m_t on the lower side of the allowed range; including the direct constraint $M_H \geq 60$ GeV, the best fit is for $M_H=60$ GeV, with the limit $M_H<320(430)$ GeV at 90(95)% CL. However, one should be cautious because the M_H constraint is driven almost entirely by R_b and A_{LR} , both of which deviate from the Standard Model prediction. Using $\alpha(M_Z)$ and \widehat{s}_Z^2 as inputs, one can predict $\alpha_s(M_Z)$ assuming grand unification. One predicts [61] $\alpha_s(M_Z) = 0.130 \pm 0.001 \pm 0.01$ for the simplest theories based on the minimal supersymmetric extension of the Standard Model, where the first (second) uncertainty is from the inputs (thresholds). This is consistent with the experimental $\alpha_s(M_Z) = 0.121(4)(1)$ from the Zlineshape (using the lower M_H range appropriate for supersymmetry) and with the average 0.118 ± 0.003 (see our Section 9 on "Quantum Chromodynamics" in this Review), but is high compared to some low-energy determinations of α_s [60]. Nonsupersymmetric unified theories predict the low value $\alpha_s(M_Z) = 0.073 \pm 0.001 \pm 0.001$.

One can also determine the radiative correction parameters Δr : including the CDF and DØ data, one obtains $\Delta r = 0.039 \pm 0.003$ and $\Delta \hat{r}_W = 0.068 \pm 0.0013$, where the error includes m_t and M_H , in excellent agreement with the predictions 0.038 ± 0.005 and 0.0705 ± 0.0007 .

Table 10.4: Values obtained for s_W^2 (on-shell) and $\hat{s}_Z^2(\overline{\rm MS})$ from various reactions assuming the global best fit value $m_t=180\pm07$ GeV (for $M_H=300$ GeV), and $\alpha_s=0.123\pm0.004$. The uncertainties include the effect of 60 GeV $< M_H < 1$ TeV. The determination from Γ_Z , R, and $\sigma_{\rm had}$ uses the experimental value of M_Z , so that the values obtained are from the vertices and not the overall scale.

Reaction	s_W^2	\widehat{s}_{Z}^{2}
M_Z	0.2237 ± 0.0010	0.2316 ± 0.0005
M_W	0.2242 ± 0.0011	0.2321 ± 0.0009
$\Gamma_Z, R, \sigma_{\rm had}$	0.2239 ± 0.0013	0.2317 ± 0.0013

SLAC eD	0.216 ± 0.017	0.223 ± 0.018
All data	0.2236 ± 0.0008	0.2315 ± 0.0004

10.5. Deviations from the Standard Model

The Z pole, W mass, and neutral-current data can be used to search for and set limits on deviations from the Standard Model.

For example, the relation between M_W and M_Z is modified if there are Higgs multiplets with weak isospin > 1/2 with significant vacuum expectation values. In order to calculate to higher orders in such theories one must define a set of four fundamental renormalized parameters. It is convenient to take these as α , G_F , M_Z , and M_W ,

Table 10.3: Principal LEP and other recent observables, compared with the Standard Model predictions for $M_Z=91.1884\pm0.0022$ GeV, 60 GeV $< M_H < 1$ TeV, the global best fit value $m_t = 180 \pm 7$ GeV (for $M_H = 300$ GeV), $\alpha_s = 0.123 \pm 0.004$, and $\alpha_s(M_Z)^{-1} = 128.90 \pm 0.09$. The LEP averages [58] of the ALEPH, DELPHI, L3, and OPAL results include common systematic errors and correlations [58]. $\overline{s}_{\ell}^2(A_{FB}^{(0,q)})$ is the effective angle extracted from the hadronic-charge asymmetry. A_{LR}^0 includes all data from 1992–1995 [48,49]. The values of $\Gamma(\ell\ell)$, $\Gamma(\text{had})$, and $\Gamma(\text{inv})$ are not independent of Γ_Z , R, and σ_{had} . The M_W value is from CDF, UA2, and DØ [59]. M_W and M_Z are correlated, but the effect is negligible due to the tiny M_Z error. The two values of s_W^2 from deep-inelastic scattering are from CCFR [31] and the global average, respectively. The $g_{VA}^{\nu e}$ are from CHARM II [34]. The second error in Q_W (for cesium) is theoretical [41]. Older low-energy results are not listed but are included in the fits. In the Standard Model predictions, the first uncertainty is from M_Z and Δr , while the second is from m_t and M_H . The $\Delta \alpha_s = 0.004$ uncertainty leads to additional errors of $0.002 (\Gamma_Z), 0.02 (R), 0.02 (\sigma), 2.0 (\Gamma(had)).$

Quantity	Value	Standard Model
$\overline{M_Z \; ({ m GeV})}$	91.1884 ± 0.0022	input
$\Gamma_Z~({ m GeV})$	2.4963 ± 0.0032	$2.497 \pm 0.001 \pm 0.002$

since M_W and M_Z are directly measurable. Then \hat{s}_Z^2 and ρ_0 can be considered dependent parameters defined by

$$\hat{s}_Z^2 \equiv A_0^2 / M_W^2 (1 - \Delta \hat{r}_W) \tag{10.40}$$

and

$$\rho_0 \equiv M_W^2 / (M_Z^2 \,\hat{c}_Z^2 \,\hat{\rho}) \ . \tag{10.41}$$

Provided that the new physics which yields $\rho_0 \neq 1$ is a small perturbation which does not significantly affect the radiative corrections, ρ_0 can be regarded as a phenomenological parameter which multiplies G_F in Eqs. (10.12)–(10.14), (10.28), and Γ_Z in Eq. (10.36). (Also, the expression for M_Z is divided by $\sqrt{\rho_0}$;

Table 10.5: Values of \widehat{s}_Z^2 and s_W^2 (in parentheses), α_s , and m_t for various combinations of observables. The central values are for $M_H=300$ GeV, and the second set of errors is for $M_H\to 1000(+),\,60(-)$.

Data	$\widehat{s}_{Z}^{2} (s_{W}^{2})$	α_s (M_Z)	$m_t \; ({ m GeV})$
Indirect + CDF + DQ	0.2315(2)(3) $0.2236 \pm 0.0008)$	0.123(4)(2)	$180 \pm 7_{-13}^{+12}$
All indirect	0.2315(2)(2) (0.2236 ± 0.0009)	0.123(4)(2)	$179 \pm 8^{+17}_{-20}$
All LEP	0.2318(3)(2) (0.2246 ± 0.0011)	0.124(4)(2)	$171 \pm 10^{+18}_{-20}$
$SLD + M_Z$	$0.2302(5)(0) \\ (0.2184 \pm 0.0020)$		$220^{+14}_{-15}{}^{+19}_{-24}$
Z pole (LEP + SLD)	$0.2314(3)(1) (0.2234 \pm 0.0010)$	0.123(4)(2)	181 ⁺⁸⁺¹⁸ ₋₉₋₂₀

the M_W formula is unchanged.) There is now enough data to determine ρ_0 , $\sin^2\theta_W$, m_t , and α_s simultaneously. In particular, R_b and the direct CDF and DØ events yield m_t independent of ρ_0 , the asymmetries yield \widehat{s}_Z^2 , R gives α_s , and M_Z and the widths constrain ρ_0 . From the global fit (including CDF and DØ),

$$\rho_0 = 1.0012 \pm 0.0013 \pm 0.0018 \tag{10.42}$$

$$\hat{s}_Z^2 = 0.2314 \pm 0.0002 \pm 0.0002 \tag{10.43}$$

$$\alpha_s = 0.121 \pm 0.004 \pm 0.001 \tag{10.44}$$

$$m_t = 171 \pm 12 \;, \tag{10.45}$$

where the second error is from M_H . This is in remarkable agreement with the Standard Model expectation $\rho_0=1$, and constrains any higher-dimensional Higgs representation to have vacuum expectation values of less than a few percent of those of the doublets. The allowed regions in the $\rho_0 - \widehat{s}_Z^2$ plane are shown in Fig. 10.2. Allowing for new physics in R_b , one obtains $\rho_0=1.0002(14)(18)$ and $\alpha_s=0.101(8)(1)$. The effects of other types of new physics are described in Sec. 14 on "Constraints on New Physics from Electroweak Analyses" in this Review.

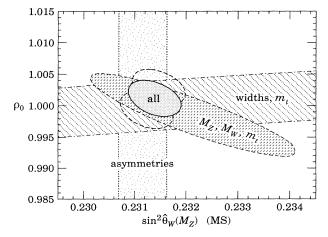

Figure 10.2: The allowed regions in $\sin^2 \widehat{\theta}_W - \rho_0$ at 90% CL. m_t is a free parameter and $M_H = 300$ GeV is assumed. (The upper (lower) dashed contours are for $M_H = 1000$ (60) GeV.) The horizontal (width) band uses the experimental value of M_Z in Eq. (10.36).

Most of the parameters relevant to ν -hadron, νe , e-hadron, and e^+e^- processes are determined uniquely and precisely from the data in "model independent" fits (i.e., fits which allow for an arbitrary electroweak gauge theory). The values for the parameters defined in Eqs. (10.12)–(10.14) are given in Table 10.6 along with the predictions of the Standard Model. The agreement is excellent. The low-energy e^+e^- results are difficult to present in a model-independent way because Z-propagator effects are non-negligible at TRISTAN, PETRA, and PEP energies. However, assuming $e^-\mu^-\tau$ universality, the lepton asymmetries imply [45] $4(g_A^e)^2=0.99\pm0.05$, in good agreement with the Standard Model prediction \simeq 1. The much more precisely measured Z-pole parameters in Table 10.3 are in excellent agreement with the Standard Model.

Table 10.6: Values of the model-independent neutral-current parameters, compared with the Standard Model prediction using $M_Z = 91.1884$ GeV for $m_t = 180 \pm 7$ GeV and $M_H = 300$ GeV. There is a second $g_{V,A}^{\nu e}$ solution, given approximately by $g_V^{\nu e} \leftrightarrow g_A^{\nu e}$, which is eliminated by e^+e^- data under the assumption that the neutral current is dominated by the exchange of a single Z. θ_i , i = L or R, is defined as $\tan^{-1}[\epsilon_i(u)/\epsilon_i(d)]$.

Quantity	Experimental Value	Standard Model Prediction	Correlation
$\epsilon_L(u)$	0.332 ± 0.016	$0.345 {\pm} 0.0003$	
$\epsilon_L(d)$	-0.438 ± 0.012	$-0.429{\pm}0.0004$	non-

11. THE CABIBBO-KOBAYASHI-MASKAWA MIXING MATRIX

Updated 1995 by F.J. Gilman, K. Kleinknecht, and B. Renk.

In the Standard Model with $SU(2) \times U(1)$ as the gauge group of electroweak interactions, both the quarks and leptons are assigned to be left-handed doublets and right-handed singlets. The quark mass eigenstates are not the same as the weak eigenstates, and the matrix relating these bases was defined for six quarks and given an explicit parametrization by Kobayashi and Maskawa [1] in 1973. It generalizes the four-quark case, where the matrix is parametrized by a single angle, the Cabibbo angle [2].

By convention, the three charge 2e/3 quarks (u, c, and t) are unmixed, and all the mixing is expressed in terms of a 3×3 unitary matrix V operating on the charge -e/3 quarks (d, s, and b):

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} . \tag{11.1}$$

The values of individual matrix elements can in principle all be determined from weak decays of the relevant quarks, or, in some cases, from deep inelastic neutrino scattering. Using the constraints discussed below together with unitarity, and assuming only three generations, the 90% confidence limits on the magnitude of the elements of the complete matrix are:

$$\begin{pmatrix} 0.9745 \text{ to } 0.9757 & 0.219 & \text{to } 0.224 & 0.002 & \text{to } 0.005 \\ 0.218 & \text{to } 0.224 & 0.9736 & \text{to } 0.9750 & 0.036 & \text{to } 0.046 \\ 0.004 & \text{to } 0.014 & 0.034 & \text{to } 0.046 & 0.9989 & \text{to } 0.9993 \end{pmatrix} \ . \ (11.2)$$

The ranges shown are for the individual matrix elements. The constraints of unitarity connect different elements, so choosing a specific value for one element restricts the range of others.

There are several parametrizations of the Cabibbo-Kobayashi-Maskawa matrix. In view of the need for a "standard" parametrization in the literature, we advocate:

$$V = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta_{13}} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta_{13}} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta_{13}} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta_{13}} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta_{13}} & c_{23}c_{13} \end{pmatrix} (11.3)$$

proposed by Chau and Keung [3]. The choice of rotation angles follows earlier work of Maiani [4], and the placement of the phase follows that of Wolfenstein [5]. The notation used is that of Harari and Leurer [6] who, along with Fritzsch and Plankl [7], proposed this parametrization as a particular case of a form generalizable to an arbitrary number of "generations." The general form was also put forward by Botella and Chau [8]. Here $c_{ij} = \cos\theta_{ij}$ and $s_{ij} = \sin\theta_{ij}$, with i and j being "generation" labels, $\{i,j=1,2,3\}$. In the limit $\theta_{23} = \theta_{13} = 0$ the third generation decouples, and the situation reduces to the usual Cabibbo mixing of the first two generations with θ_{12} identified with the Cabibbo angle [2].

The real angles θ_{12} , θ_{23} , θ_{13} can all be made to lie in the first quadrant by an appropriate redefinition of quark field phases. Then all s_{ij} and c_{ij} are positive, $|V_{us}| = s_{12}c_{13}$, $|V_{ub}| = s_{13}$, and $|V_{cb}| = s_{23}c_{13}$. As c_{13} is known to deviate from unity only in the fifth decimal place, $|V_{us}| = s_{12}$, $|V_{ub}| = s_{13}$, and $|V_{cb}| = s_{23}$ to an excellent approximation. The phase δ_{13} lies in the range $0 \le \delta_{13} < 2\pi$, with non-zero values generally breaking CP invariance for the weak interactions. The generalization to the n generation case contains n(n-1)/2 angles and (n-1)(n-2)/2 phases [6,7,8]. The range of matrix elements in Eq. (11.2) corresponds to 90% CL limits on the angles of $s_{12} = 0.219$ to $0.223, s_{23} = 0.036$ to 0.046, and $s_{13} = 0.002$ to 0.005.

Kobayashi and Maskawa [1] originally chose a parametrization involving the four angles, θ_1 , θ_2 , θ_3 , δ :

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} c_1 & -s_1 c_3 & -s_1 s_3 \\ s_1 c_2 & c_1 c_2 c_3 - s_2 s_3 e^{i\delta} & c_1 c_2 s_3 + s_2 c_3 e^{i\delta} \\ s_1 s_2 & c_1 s_2 c_3 + c_2 s_3 e^{i\delta} & c_1 s_2 s_3 - c_2 c_3 e^{i\delta} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} , \qquad (11.4)$$

where $c_i=\cos\theta_i$ and $s_i=\sin\theta_i$ for i=1,2,3. In the limit $\theta_2=\theta_3=0$, this reduces to the usual Cabibbo mixing with θ_1 identified (up to a sign) with the Cabibbo angle [2]. Slightly different forms of the Kobayashi-Maskawa parametrization are found in the literature. The CKM matrix used in the 1982 Review of Particle Properties is obtained by letting $s_1\to -s_1$ and $\delta\to\delta+\pi$ in the matrix given above. An alternative is to change Eq. (11.4) by $s_1\to -s_1$ but leave δ unchanged. With this change in s_1 , the angle θ_1 becomes the usual Cabibbo angle, with the "correct" sign (i.e. $d'=d\cos\theta_1+s\sin\theta_1$) in the limit $\theta_2=\theta_3=0$. The angles $\theta_1,\theta_2,\theta_3$ can, as before, all be taken to lie in the first quadrant by adjusting quark field phases. Since all these parametrizations are referred to as "the" Kobayashi-Maskawa form, some care about which one is being used is needed when the quadrant in which δ lies is under discussion.

Other parametrizations, mentioned above, are due to Maiani [4] and to Wolfenstein [5]. Still other parametrizations [9] have come into the literature in connection with attempts to define "maximal CP violation". No physics can depend on which of the above parametrizations (or any other) is used as long as a single one is used consistently and care is taken to be sure that no other choice of phases is in conflict.

Our present knowledge of the matrix elements comes from the following sources: $% \left(1\right) =\left(1\right) \left(1\right) \left($

(1) New analyses have been performed comparing nuclear beta decay to muon decay. The previous radiative corrections [10] already included order $Z\alpha^2$ effects and more recent results [11–15] concentrate on nuclear mismatch and structure-dependent radiative corrections. The results in Ref. 15 violate CVC, and the updated [13] average ft values for superallowed 0^+ to 0^+ transitions of Refs. 11 and 12 do not agree with each other within the estimated uncertainties:

$$ft = 3150.8 \pm 1.7 \text{ sec}$$
 (Refs. 11 and 13),
 $ft = 3145.7 \pm 1.5 \text{ sec}$ (Refs. 12 and 13), (11.5)

The common experimental error is ± 0.82 . We have taken an average of the above values and scaled up the error to take account of the uncertainty in the nuclear structure dependent radiative corrections and corresponding inconsistency of the theoretical results. This transforms to

$$|V_{ud}| = 0.9736 \pm 0.0010 , (11.6)$$

which is almost one standard deviation smaller than the result in the previous Review of Particle Physics. It is consistent with the result $|V_{ud}| = 0.9734 \pm 0.0007$ from the update in Ref. 14.

(2) Analysis of K_{e3} decays yields [16]

$$|V_{us}| = 0.2196 \pm 0.0023 \ . \tag{11.7}$$

With isospin violation taken into account in K^+ and K^0 decays, the extracted values of $|V_{us}|$ are in agreement at the 1% level. A reanalysis [13] obtains essentially the same value, but quotes a somewhat smaller error which is only statistical. The analysis of hyperon decay data has larger theoretical uncertainties because of first order SU(3) symmetry breaking effects in the axial-vector couplings, but due account of symmetry breaking [17] applied to the WA2 data [18] gives a corrected value [19] of 0.222 ± 0.003 . We average these two results to obtain:

$$|V_{us}| = 0.2205 \pm 0.0018 \ . \tag{11.8}$$

(3) The magnitude of $|V_{cd}|$ may be deduced from neutrino and antineutrino production of charm off valence d quarks. The dimuon production cross sections of the CDHS group [20] yield $\overline{B}_c |V_{cd}|^2 = 0.41 \pm 0.07 \times 10^{-2}$, where \overline{B}_c is the semileptonic branching fraction of the charmed hadrons produced. The corresponding value from a more recent Tevatron experiment [21], where a next-to-leading-order

QCD analysis has been carried out, is $0.534 \pm 0.021^{+0.025}_{-0.051} \times 10^{-2}$, where the last error is from the scale uncertainty. Assuming a similar scale error for the CDHS result and averaging these two results gives $0.49 \pm 0.05 \times 10^{-2}$. Supplementing this with data [22] on the mix of charmed particle species produced by neutrinos and PDG values for their semileptonic branching fractions to give [21] $\overline{B}_c = 0.099 \pm 0.012$, yields

$$|V_{cd}| = 0.224 \pm 0.016 \tag{11.9}$$

(4) Values of $|V_{cs}|$ from neutrino production of charm are dependent on assumptions about the strange quark density in the parton-sea. The most conservative assumption, that the strange-quark sea does not exceed the value corresponding to an SU(3) symmetric sea, leads to a lower bound [20], $|V_{cs}| > 0.59$. It is more advantageous to proceed analogously to the method used for extracting $|V_{us}|$ from K_{e3} decay; namely, we compare the experimental value for the width of D_{e3} decay with the expression [23] that follows from the standard weak interaction amplitude:

$$\Gamma(D \to \overline{K}e^+\nu_e) = |f_+^D(0)|^2 |V_{cs}|^2 (1.54 \times 10^{11} \text{ s}^{-1}).$$
 (11.10)

Here $f_+^D(q^2)$, with $q=p_D-p_K$, is the form factor relevant to D_{e3} decay; its variation has been taken into account with the parametrization $f_+^D(t)/f_+^D(0)=M^2/(M^2-t)$ and $M=2.1~{\rm GeV}/c^2$, a form and mass consistent with Mark III and E691 measurements [24,25]. Combining data on branching ratios for D_{e3} decays from Mark III, E691, and CLEO experiments [24–26] with accurate values [27] for τ_{D^+} and τ_{D^0} , yields $(0.762\pm0.055)\times10^{11}~{\rm s}^{-1}$ for $\Gamma(D\to\overline{K}e^+\nu_e)$. Therefore

$$|f_{+}^{D}(0)|^{2} |V_{cs}|^{2} = 0.495 \pm 0.036$$
 (11.11)

A very conservative assumption is that $|f_+^D(0)| < 1$, from which it follows that $|V_{cs}| > 0.62$. Calculations of the form factor either performed [28,29] directly at $q^2 = 0$, or done [30] at the maximum value of $q^2 = (m_D - m_K)^2$ and interpreted at $q^2 = 0$ using the measured q^2 dependence, gives the value $f_+^D(0) = 0.7 \pm 0.1$. It follows that

$$|V_{cs}| = 1.01 \pm 0.18 \ . \tag{11.12}$$

The constraint of unitarity when there are only three generations gives a much tighter bound (see below).

(5) The ratio $|V_{ub}/V_{cb}|$ can be obtained from the semileptonic decay of B mesons produced on the $\Upsilon(4S)$ $b\bar{b}$ resonance by measuring the lepton energy spectrum above the endpoint of the $b \to c\ell\nu$ spectrum. There the $b \to u\ell\nu$ decay rate can be obtained by subtracting the background from nonresonant e^+e^- reactions. This continuum background is determined from auxiliary measurements off the $\Upsilon(4S)$. Both the CLEO [31] and ARGUS [32] collaborations have reported evidence for $b \to u$ transitions in semileptonic B decays. The interpretation of the result in terms of $|V_{ub}/V_{cb}|$ depends fairly strongly on the theoretical model used to generate the lepton energy spectrum, especially for $b \to u$ transitions [29,30,33]. Combining the experimental and theoretical uncertainties, we quote

$$|V_{ub}/V_{cb}| = 0.08 \pm 0.02 \ . \tag{11.13}$$

(6) The heavy quark effective theory [34](HQET) provides a nearly model-independent treatment of B semileptonic decays to charmed mesons. From measurements [35–37] of the exclusive decay $B \to \overline{D}^* \overline{\ell} \nu_\ell$, the value $|V_{cb}| = 0.041 \pm 0.003 \pm 0.002$ has been extracted [38] using corrections based on the HQET. A new analysis of inclusive decays [39], where the measured semileptonic bottom hadron partial width is assumed to be that of a b quark decaying through the usual V - A interaction, gives $|V_{cb}| \cdot (\tau_b/1.5 \text{ ps})^{1/2} = 0.041 \pm 0.002$. Using a value [40] for the b lifetime $\tau_b = 1.55 \pm 0.06$ ps and combining with the exclusive result, we obtain

$$|V_{cb}| = 0.041 \pm 0.003 \ . \tag{11.14}$$

The results for three generations of quarks, from Eqs. 11.6, 11.8, 11.9, 11.12, 11.13, and 11.14 plus unitarity, are summarized in the matrix in Eq. (11.2). The ranges given there are different from those given in Eqs. (11.6)–(11.14) because of the inclusion of unitarity, but are consistent with the one-standard-deviation errors on the input matrix elements. Note in particular that the unitarity constraint has pushed $|V_{ud}|$ about one standard deviation higher than given in Eq. (11.6).

The data do not preclude there being more than three generations. Moreover, the entries deduced from unitarity might be altered when the CKM matrix is expanded to accommodate more generations. Conversely, the known entries restrict the possible values of additional elements if the matrix is expanded to account for additional generations. For example, unitarity and the known elements of the first row require that any additional element in the first row have a magnitude $|V_{ub'}| < 0.08$. When there are more than three generations the allowed ranges (at 90% CL) of the matrix elements connecting the first three generations are

$$\begin{pmatrix} 0.9720 \text{ to } 0.9752 & 0.217 \text{ to } 0.223 & 0.002 \text{ to } 0.005 & \dots \\ 0.199 & \text{to } 0.234 & 0.818 \text{ to } 0.975 & 0.036 \text{ to } 0.046 & \dots \\ 0 & \text{to } 0.11 & 0 & \text{to } 0.52 & 0 & \text{to } 0.9993 \dots \\ \vdots & \vdots & \vdots & \vdots & \vdots \end{pmatrix}, (11.15)$$

where we have used unitarity (for the expanded matrix) and Eqs. 11.6, 11.8, 11.9, 11.12, 11.13, and 11.14.

Further information, particularly on CKM matrix elements involving the top quark, can be obtained from flavor-changing processes that occur at the one-loop level. We have not used this information in the discussion above since the derivation of values for V_{td} and V_{ts} in this manner from, for example, B mixing, $b \to s \gamma$, or $K \to \pi \nu \overline{\nu}$, requires an additional assumption that the top-quark loop, rather than new physics, gives the dominant contribution to the process in question.

The measured value [41] of $\Delta M_d = 0.496 \pm 0.032~{\rm ps}^{-1}$ from $B_d^0 - \overline{B}_d^0$ mixing can be turned in this way into information on $|V_{tb}^*V_{td}|$. Using $\widehat{B}_{Bd}f_{Bd}^2 = (1.2 \pm 0.2)(173 \pm 40~{\rm MeV})^2$ from lattice QCD calculations [42], next-to-leading-order QCD corrections [43], and $m_t = 174 \pm 16~{\rm GeV}$ as input,

$$|V_{tb}^* V_{td}| = 0.009 \pm 0.003 , \qquad (11.16)$$

where the error bar comes primarily from the theoretical uncertainty in the hadronic matrix elements.

In the ratio of B_s to B_d mass differences, many of the factors (such as the QCD correction and dependence on the t-quark mass) cancel, and we have

$$\frac{\Delta M_{B_s}}{\Delta M_{B_d}} = \frac{\widehat{B}_{B_s} f_{B_s}^2}{\widehat{B}_{B_d} f_{B_d}^2} \frac{|V_{tb}^* \cdot V_{ts}|^2}{|V_{tb}^* \cdot V_{td}|^2} \ . \tag{11.17}$$

With $\widehat{B}_{B_s} \approx \widehat{B}_{B_d}$ and $f_{B_s}/f_{B_d} = 1.16 \pm 0.10$ from lattice QCD [42] and the experimental limit [41] $\Delta M_{B_s}/\Delta M_{B_d} > 11.6$,

$$|V_{td}|/|V_{ts}| < 0.37. (11.18)$$

The CLEO observation [44] of $b \to s \gamma$ can be translated [45] similarly into $|V_{ts}|/|V_{cb}|=1.1\pm0.43$, where the large uncertainty is again dominantly theoretical. Ultimately $K\to \pi\nu\bar{\nu}$ decays offer high precision because the matrix elements can be directly measured, but experiment is presently several orders of magnitude away from the requisite sensitivity. All these additional indirect constraints are consistent with the matrix elements obtained from the direct measurements plus unitarity, assuming three generations; adding the indirect constraints to the fit leaves the ranges of CKM matrix elements in Eq. (11.2) essentially unchanged.

Direct and indirect information on the CKM matrix is neatly summarized in terms of the "unitarity triangle." The name arises since unitarity of the 3×3 CKM matrix applied to the first and third columns yields

$$V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0. (11.19)$$

The unitarity triangle is just a geometrical presentation of this equation in the complex plane [46]. We can always choose to orient the triangle so that $V_{cd} V_{cb}^*$ lies along the horizontal; in the parametrization we have chosen, V_{cb} is real, and V_{cd} is real to a very good approximation in any case. Setting cosines of small angles to unity, Eq. (11.19) becomes

$$V_{ub}^* + V_{td} = s_{12} V_{cb}^* , (11.20)$$

which is shown as the unitarity triangle in Fig. 11.1(a). Rescaling the triangle by a factor $[1/|s_{12}|V_{cb}|]$, the coordinates of the vertices become

$$A(\text{Re}(V_{ub})/|s_{12}V_{cb}|, -\text{Im}(V_{ub})/|s_{12}V_{cb}|)$$
, $B(1,0)$, $C(0,0)$. (11.21)

In the approximation of the Wolfenstein parametrization [5], with matrix elements expressed in powers of the Cabibbo angle, $\lambda \sim s_{12}$:

$$V_{us} \sim \lambda$$

 $V_{ub} \sim \lambda^3 A(\rho - i\eta)$
 $V_{cb} \sim \lambda^2 A$
 $V_{td} \sim \lambda^3 A(1 - \rho - i\eta)$, (11.22)

the coordinates of the vertex A of the unitarity triangle are simply (ρ, η) , as shown in Fig. 11.1(b).

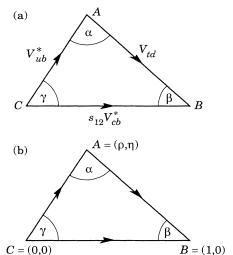

Figure 11.1: (a) Representation in the complex plane of the triangle formed by the CKM matrix elements V_{ub}^* , V_{td} , and $s_{12} V_{cb}^*$. (b) Rescaled triangle with vertices $A(\rho, \eta)$, B(1, 0), and C(0, 0).

CP-violating processes will involve the phase in the CKM matrix, assuming that the observed CP violation is solely related to a nonzero value of this phase. This allows additional constraints to be brought to bear. More specifically, a necessary and sufficient condition for \overline{CP} violation with three generations can be formulated in a parametrization-independent manner in terms of the non-vanishing of the determinant of the commutator of the mass matrices for the charge 2e/3 and charge -e/3 quarks [47]. CP violating amplitudes or differences of rates all are proportional to the CKM factor in this quantity. This is the product of factors $s_{12}s_{13}s_{23}c_{12}c_{13}^2c_{23}s_{\delta_{13}}$ in the parametrization adopted above, and is $s_1^2 s_2 s_3 c_1 c_2 c_3 s_\delta$ in that of Ref. 1. With the approximation of setting cosines to unity, this is just twice the area of the unitarity triangle. While hadronic matrix elements whose values are imprecisely known generally now enter, the constraints from CP violation in the neutral kaon system are tight enough to very much restrict the range of angles and the phase of the CKM matrix. For example, the constraint obtained from the

CP-violating parameter ϵ in the neutral K system corresponds to the vertex A of the unitarity triangle lying on a hyperbola for fixed values of the hadronic matrix elements. [48] For CP-violating asymmetries of neutral B mesons decaying to CP eigenstates, there is a direct relationship between the magnitude of the asymmetry in a given decay and $\sin 2\phi$, where $\phi = \alpha$, β , γ is an appropriate angle of the unitarity triangle [46].

The combination of all the direct and indirect information can be used to find the overall constraints on the CKM matrix and thence the implications for future measurements of CP violation in the B system [48].

12. QUARK MODEL

12.1. Quantum numbers of the quarks

Each quark has spin 1/2 and baryon number 1/3. Table 12.1 gives the additive quantum numbers (other than baryon number) of the three generations of quarks. Our convention is that the flavor of a quark (I_z , S, C, B, or T) has the same sign as its charge. With this convention, any flavor carried by a charged meson has the same sign as its charge; e.g., the strangeness of the K^+ is +1, the bottomness of the B^+ is +1, and the charm and strangeness of the D_s^- are each -1.

By convention, each quark is assigned positive parity. Then each antiquark has negative parity.

Table 12.1: Additive quantum numbers of the quarks.

Property Quark	d	u	s	c	ь	t
Q – electric charge	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$
I_z – isospin z-component	$-\frac{1}{2}$	$+\frac{1}{2}$	0	0	0	0
S – strangeness	0	0	-1	0	0	0
C – charm	0	0	0	+1	0	0
B – bottomness	0	0	0	0	-1	0
T – topness	0	0	0	0	0	+1

12.2. Mesons: $q\overline{q}$ states

Nearly all known mesons are bound states of a quark q and an antiquark \overline{q}' (the flavors of q and q' may be different). If the orbital angular momentum of the $q\overline{q}'$ state is L, then the parity P is $(-1)^{L+1}$. A state $q\overline{q}$ of a quark and its own antiquark is also an eigenstate of charge conjugation, with $C=(-1)^{L+S}$, where the spin S is 0 or 1. The L=0 states are the pseudoscalars, $J^P=0^-$, and the vectors, $J^P=1^-$. Assignments for many of the known mesons are given in Table 12.2. States in the "normal" spin-parity series, $P=(-1)^J$, must, according to the above, have S=1 and hence CP=+1. Thus mesons with normal spin-parity and CP=-1 are forbidden in the $q\overline{q}'$ model. The $J^{PC}=0^{--}$ state is forbidden as well. Mesons with such J^{PC} may exist, but would lie outside the $q\overline{q}'$ model.

The nine possible $q\overline{q}'$ combinations containing $u,\ d,$ and s quarks group themselves into an octet and a singlet:

$$\mathbf{3} \otimes \overline{\mathbf{3}} = \mathbf{8} \oplus \mathbf{1} \tag{12.1}$$

States with the same IJ^P and additive quantum numbers can mix. (If they are eigenstates of charge conjugation, they must also have the same value of C.) Thus the I=0 member of the ground-state pseudoscalar octet mixes with the corresponding pseudoscalar singlet to produce the η and η' . These appear as members of a nonet, which is shown as the middle plane in Fig. 12.1(a). Similarly, the ground-state vector nonet appears as the middle plane in Fig. 12.1(b).

A fourth quark such as charm can be included in this scheme by extending the symmetry to SU(4), as shown in Fig. 12.1. Bottom extends the symmetry to SU(5); to draw the multiplets would require four dimensions.

For the pseudoscalar mesons, the Gell-Mann-Okubo formula is

$$m_{\eta}^2 = \frac{1}{3}(4m_K^2 - m_{\pi}^2) , \qquad (12.2)$$

assuming no octet-singlet mixing. However, the octet η_8 and singlet η_1 mix because of SU(3) breaking. In general, the mixing angle is mass dependent and becomes complex for resonances of finite width.

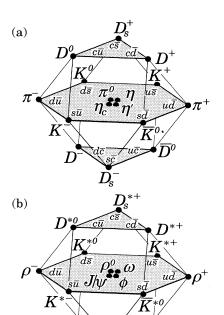

Figure 12.1: SU(4) 16-plets for the (a) pseudoscalar and (b) vector mesons made of u, d, s, and c quarks. The nonets of light mesons occupy the central planes, to which the $c\overline{c}$ states have been added. The neutral mesons at the centers of these planes are mixtures of $u\overline{u}$, $d\overline{d}$, $s\overline{s}$, and $c\overline{c}$ states.

 D_s^*

Neglecting this, the physical states η and η' are given in terms of a mixing angle θ_P by

$$\eta = \eta_8 \cos \theta_P - \eta_1 \sin \theta_P \tag{12.3a}$$

$$\eta' = \eta_8 \sin \theta_P + \eta_1 \cos \theta_P \ . \tag{12.3b}$$

These combinations diagonalize the mass-squared matrix

$$M^2 = \begin{pmatrix} M_{11}^2 & M_{18}^2 \\ M_{18}^2 & M_{88}^2 \end{pmatrix} , {12.4}$$

where $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)$. It follows that

$$\tan^2 \theta_P = \frac{M_{88}^2 - m_{\eta}^2}{m_{\eta'}^2 - M_{88}^2} \,. \tag{12.5}$$

The sign of θ_P is meaningful in the quark model. If

$$\eta_1 = (u\overline{u} + d\overline{d} + s\overline{s})/\sqrt{3} \tag{12.6a}$$

$$\eta_8 = (u\overline{u} + d\overline{d} - 2s\overline{s})/\sqrt{6} , \qquad (12.6b)$$

then the matrix element M_{18}^2 , which is due mostly to the strange quark mass, is negative. From the relation

$$\tan \theta_P = \frac{M_{88}^2 - m_{\eta}^2}{M_{18}^2} \,, \tag{12.7}$$

we find that $\theta_P < 0$. However, caution is suggested in the use of the $\eta - \eta'$ mixing-angle formulas, as they are extremely sensitive to SU(3)

Table 12.2: Suggested $q\overline{q}$ quark-model assignments for most of the known mesons. Some assignments, especially for the 0^{++} multiplet and for some of the higher multiplets, are controversial. Mesons in bold face are included in the Meson Summary Table. Of the light mesons in the Summary Table, the $f_1(1420)$, $f_0(1500)$, $f_J(1710)$, $f_2(2300)$, $f_2(2340)$, and the two peaks in the $\eta(1440)$ entry are not in this table. Within the $q\overline{q}$ model, it is especially hard to find a place for the first three of these f mesons and for one of the $\eta(1440)$ peaks. See the "Note on Non- $q\overline{q}$ Mesons" at the end of the Meson Listings.

^{*} See our scalar minireview in the Particle Listings. The candidates for the I=1 states are $a_0(980)$ and $a_0(1450)$, while for I=0 they are: $f_0(400-1200)$, $f_0(980)$, and $f_0(1370)$. The light scalars are problematic, since there may be two poles for one $q\bar{q}$ state and $a_0(980)$, $f_0(980)$ may be $K\bar{K}$ bound states.

If we allow $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)$ $(1 + \Delta)$, the mixing angle is determined by

$$\tan^2 \theta_P = 0.0319(1 + 17\Delta) \tag{12.8}$$

$$\theta_P = -10.1^{\circ} (1 + 8.5\Delta) \tag{12.9}$$

to first order in Δ . A small breaking of the Gell-Mann-Okubo relation can produce a major modification of θ_P .

For the vector mesons, $\pi \to \rho$, $K \to K^*$, $\eta \to \phi$, and $\eta' \to \omega$, so

$$\phi = \omega_8 \cos \theta_V - \omega_1 \sin \theta_V \tag{12.10}$$

$$\omega = \omega_8 \sin \theta_V + \omega_1 \cos \theta_V \ . \tag{12.11}$$

For "ideal" mixing, $\phi=s\overline{s}$, so $\tan\theta_V=1/\sqrt{2}$ and $\theta_V=35.3^\circ$. Experimentally, θ_V is near 35°, the sign being determined by a formula like that for $\tan\theta_P$. Following this procedure we find the mixing angles given in Table 12.3.

Table 12.3: Singlet-octet mixing angles for several nonets, neglecting possible mass dependence and imaginary parts. The sign conventions are given in the text. The values of $\theta_{\rm quad}$ are obtained from the equations in the text, while those for $\theta_{\rm lin}$ are obtained by replacing m^2 by m throughout. Of the two isosinglets in a nonet, the mostly octet one is listed first.

J^{PC}	Nonet members	$\theta_{\rm quad}$	$\theta_{ m lin}$
0^{-+}	π,K,η,η'	-10°	-23°
1	$\rho, K^*(892), \phi, \omega$	39°	36°
2^{++}	$a_2(1320), K_2^*(1430), f_2'(1525), f_2(1270)$	28°	26°
$3^{}$	$\rho_3(1690), K_3^*(1780), \phi_3(1850), \omega_3(1670)$	29°	28°

 $^{^\}dagger$ The K_{1A} and K_{1B} are nearly equal (45°) mixes of the $K_1(1270)$ and $K_1(1400).$

[‡]The $K^*(1410)$ could be replaced by the $K^*(1680)$ as the 2 3S_1 state.

In the quark model, the coupling of neutral mesons to two photons is proportional to $\sum_i Q_i^2$, where Q_i is the charge of the *i*-th quark. This provides an alternative characterization of mixing. For example, defining

$$\operatorname{Amp}\left[P \to \gamma(k_1) \ \gamma(k_2)\right] = M \epsilon^{\mu\nu\alpha\beta} \ \epsilon_{1\mu}^* \ k_{1\nu} \ \epsilon_{2\alpha}^* \ k_{2\beta} \ , \tag{12.12}$$

where $\epsilon_{i\lambda}$ is the λ component of the polarization vector of the i^{th} photon, one finds

$$\begin{split} \frac{M(\eta \to \gamma \gamma)}{M(\pi^0 \to \gamma \gamma)} &= \frac{1}{\sqrt{3}} (\cos \theta_P - 2\sqrt{2} \sin \theta_P) \\ &= \frac{1.73 \pm 0.18}{\sqrt{3}} \end{split} \tag{12.13a}$$

$$\frac{M(\eta' \to \gamma \gamma)}{M(\pi^0 \to \gamma \gamma)} = 2\sqrt{2/3} \left(\cos \theta_P + \frac{\sin \theta_P}{2\sqrt{2}}\right)$$
$$= 2\sqrt{2/3} \left(0.78 \pm 0.04\right) , \qquad (12.13b)$$

where the numbers with errors are experimental. These data favor $\theta_P \approx -20^\circ$, which is compatible with the quadratic mass mixing formula with about 12% SU(3) breaking in M_{88}^2 .

12.3. Baryons: qqq states

All the established baryons are apparently 3-quark (qqq) states, and each such state is an SU(3) color singlet, a completely antisymmetric state of the three possible colors. Since the quarks are fermions, the state function for any baryon must be antisymmetric under interchange of any two equal-mass quarks (up and down quarks in the limit of isospin symmetry). Thus the state function may be written as

$$|qqq\rangle_A = |\operatorname{color}\rangle_A \times |\operatorname{space}, \operatorname{spin}, \operatorname{flavor}\rangle_S,$$
 (12.14)

where the subscripts S and A indicate symmetry or antisymmetry under interchange of any two of the equal-mass quarks. Note the contrast with the state function for the three nucleons in $^3\mathrm{H}$ or $^3\mathrm{He}$:

$$|NNN\rangle_A = |\operatorname{space}, \operatorname{spin}, \operatorname{isospin}\rangle_A$$
. (12.15)

This difference has major implications for internal structure, magnetic moments, etc. (For a nice discussion, see Ref. 1.)

The "ordinary" baryons are made up of u, d, and s quarks. The three flavors imply an approximate flavor SU(3), which requires that baryons made of these quarks belong to the multiplets on the right side of

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10}_S \oplus \mathbf{8}_M \oplus \mathbf{8}_M \oplus \mathbf{1}_A \tag{12.16}$$

(see Sec. 33, on "SU(n) Multiplets and Young Diagrams"). Here the subscripts indicate symmetric, mixed-symmetry, or antisymmetric states under interchange of any two quarks. The 1 is a uds state (Λ_1) and the octet contains a similar state (Λ_8). If these have the same spin and parity they can mix. An example is the mainly octet D_{03} $\Lambda(1690)$ and mainly singlet D_{03} $\Lambda(1520)$. In the ground state multiplet, the SU(3) flavor singlet Λ is forbidden by Fermi statistics. The mixing formalism is the same as for η - η' or ϕ - ω (see above), except that for baryons the mass M instead of M^2 is used. Section 32, on "SU(3) Isoscalar Factors and Representation Matrices", shows how relative decay rates in, say, $10 \to 8 \otimes 8$ decays may be calculated. A summary of results of fits to the observed baryon masses and decay rates for the best-known SU(3) multiplets is given in Appendix II of our 1982 edition [2].

The addition of the c quark to the light quarks extends the flavor symmetry to SU(4). Figures 12.2(a) and 12.2(b) show the (badly broken) SU(4) baryon multiplets that have as their "ground floors" the SU(3) octet that contains the nucleons and the SU(3) decuplet that contains the $\Delta(1232)$. All the particles in a given SU(4) multiplet have the same spin and parity. The only charmed baryons that have been discovered each contain one charmed quark. These belong to the first floor of the multiplet shown in Fig. 12.2(a); for details, see

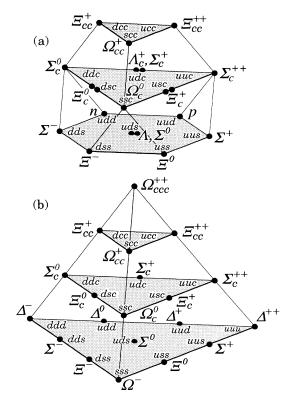

Figure 12.2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet. (b) The 20-plet with an SU(3) decuplet.

the "Note on Charmed Baryons" in the Baryon Particle Listings. The addition of a b quark extends the flavor symmetry to SU(5); it would require four dimensions to draw the multiplets.

For the "ordinary" baryons, flavor and spin may be combined in an approximate flavor-spin SU(6) in which the six basic states are $d\uparrow$, $d\downarrow$, \cdots , $s\downarrow$ (\uparrow , \downarrow = spin up, down). Then the baryons belong to the multiplets on the right side of

$$\mathbf{6} \otimes \mathbf{6} \otimes \mathbf{6} = \mathbf{56}_S \oplus \mathbf{70}_M \oplus \mathbf{70}_M \oplus \mathbf{20}_A . \tag{12.17}$$

These $\mathrm{SU}(6)$ multiplets decompose into flavor $\mathrm{SU}(3)$ multiplets as follows:

$$\mathbf{56} = {}^{4}\mathbf{10} \oplus {}^{2}\mathbf{8} \tag{12.18a}$$

$$70 = {}^{2}10 \oplus {}^{4}8 \oplus {}^{2}8 \oplus {}^{2}1 \tag{12.18b}$$

$$\mathbf{20} = {}^{2}\mathbf{8} \oplus {}^{4}\mathbf{1} , \qquad (12.18c)$$

where the superscript (2S+1) gives the net spin S of the quarks for each particle in the SU(3) multiplet. The $J^P=1/2^+$ octet containing the nucleon and the $J^P=3/2^+$ decuplet containing the $\Delta(1232)$ together make up the "ground-state" 56-plet in which the orbital angular momenta between the quark pairs are zero (so that the spatial part of the state function is trivially symmetric). The 70 and 20 require some excitation of the spatial part of the state function in order to make the overall state function symmetric. States with nonzero orbital angular momenta are classified in SU(6) \otimes O(3) supermultiplets. Physical baryons with the same quantum numbers do not belong to a single supermultiplet, since SU(6) is broken by spin-dependent interactions, differences in quark masses, etc. Nevertheless, the SU(6) \otimes O(3) basis provides a suitable framework for describing baryon state functions.

It is useful to classify the baryons into bands that have the same number N of quanta of excitation. Each band consists of a number of

supermultiplets, specified by (D, L_N^P) , where D is the dimensionality of the SU(6) representation, L is the total quark orbital angular momentum, and P is the total parity. Supermultiplets contained in bands up to N=12 are given in Ref. 3. The N=0 band, which contains the nucleon and $\Delta(1232)$, consists only of the $(56,0_0^+)$ supermultiplet. The N=1 band consists only of the $(70,1_1^-)$ multiplet and contains the negative-parity baryons with masses below about 1.9 GeV. The N=2 band contains five supermultiplets: $(56,0_2^+)$, $(70,0_2^+)$, $(56,2_2^+)$, $(70,2_2^+)$, and $(20,1_2^+)$. Baryons belonging to the $(20,1_2^+)$ supermultiplet are not ever likely to be observed, since a coupling from the ground-state baryons requires a two-quark excitation. Selection rules are similarly responsible for the fact that many other baryon resonances have not been observed [4].

In Table 12.4, quark-model assignments are given for many of the established baryons whose $SU(6)\otimes O(3)$ compositions are relatively unmixed. We note that the unestablished resonances $\mathcal{L}(1480)$, $\mathcal{L}(1560)$, $\mathcal{L}(1580)$, $\mathcal{L}(1770)$, and $\mathcal{L}(1620)$ in our Baryon Particle Listings are too low in mass to be accommodated in most quark models [4,5].

Table 12.4: Quark-model assignments for many of the known baryons in terms of a flavor-spin SU(6) basis. Only the dominant representation is listed. Assignments for some states, especially for the $\Lambda(1810)$, $\Lambda(2350)$, $\Xi(1820)$, and $\Xi(2030)$, are merely educated guesses.

12.4. Dynamics

Many specific quark models exist, but most contain the same basic set of dynamical ingredients. These include:

- i) A confining interaction, which is generally spin-independent.
- ii) A spin-dependent interaction, modeled after the effects of gluon exchange in QCD. For example, in the S-wave states, there is a spin-spin hyperfine interaction of the form

$$H_{HF} = -\alpha_S M \sum_{i>j} (\overrightarrow{\sigma} \lambda_a)_i (\overrightarrow{\sigma} \lambda_a)_j , \qquad (12.19)$$

where M is a constant with units of energy, λ_a $(a=1,\cdots,8,)$ is the set of SU(3) unitary spin matrices, defined in Sec. 32, on "SU(3) Isoscalar Factors and Representation Matrices," and the sum runs over constituent quarks or antiquarks. Spin-orbit interactions, although allowed, seem to be small.

- iii) A strange quark mass somewhat larger than the up and down quark masses, in order to split the SU(3) multiplets.
- iv) In the case of isoscalar mesons, an interaction for mixing $q\overline{q}$ configurations of different flavors (e.g., $u\overline{u} \leftrightarrow d\overline{d} \leftrightarrow s\overline{s}$), in a manner which is generally chosen to be flavor independent.

These four ingredients provide the basic mechanisms that determine the hadron spectrum.

13. CP VIOLATION

This section prepared April 1994 by L. Wolfenstein.

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. Then CP violation was observed in K^0 decays at a level given by the parameter $\epsilon = 2.3 \times 10^{-3}$. Larger CP-violation effects are anticipated in B^0 decays.

The eigenstates of the K^0 – \overline{K}^0 system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle , \qquad |K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle .$$
 (13.1)

If CP invariance held, we would have q=p so that K_S would be CP even and K_L CP odd. (We define $|\overline{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in $K^0-\overline{K}^0$ mixing gives

$$\frac{p}{q} = \frac{(1 + \widetilde{\epsilon})}{(1 - \widetilde{\epsilon})} \ . \tag{13.2}$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \to \pi\pi(I)) = A_I e^{i\delta_I}$$
, $A(\overline{K}^0 \to \pi\pi(I)) = A_I^* e^{i\delta_I}$, (13.3)

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The ratios of CP-violating to CP-conserving amplitudes $\eta_{+-} = A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-)$ and $\eta_{00} = A(K_L^0 \to \pi^0\pi^0)/A(K_S^0 \to \pi^0\pi^0)$ can be written as

$$\eta_{+-} = \epsilon + \epsilon', \qquad \eta_{00} = \epsilon - 2\epsilon',$$
(13.4a)

$$\epsilon = \tilde{\epsilon} + i \left(\text{Im } A_0 / \text{Re } A_0 \right),$$
(13.4b)

$$|\sqrt{2}\epsilon'| = (\text{Re } A_2/\text{Re } A_0) \text{ (Im } A_2/\text{Re } A_2 - \text{Im } A_0/\text{Re } A_0) . (13.4c)$$

If CP violation is confined to the mass matrix, as in a superweak theory, ϵ' is zero and $\eta_{+-} = \eta_{00} = \epsilon = \widetilde{\epsilon}$. The measurement of ϵ'/ϵ has as its goal finding an effect that requires CP violation in the decay amplitude; this corresponds to a relative phase between A_2 and A_0 as seen in Eq. (13.4c).

In the Standard Model, CP violation arises as a result of a single phase entering the CKM matrix (q.v.). As a result in what is now the standard phase convention, two elements have large phases, $V_{ub} \sim e^{-i\gamma}$, $V_{td} \sim e^{-i\beta}$. Because these elements have small magnitudes and involve the third generation, CP violation in the K^0 system is small. A definite nonzero value for ϵ'/ϵ is expected but hadronic uncertainties allow theoretical values between 10^{-4} and 3×10^{-3} . On the other hand, large effects are expected in the B^0 system, which is a major motivation for B factories.

The most clear cut experiments would be those that measure asymmetries between B^0 and $\overline{B}{}^0$ decays. The time-dependent rate to a CP eigenstate a is given by

$$\Gamma_a \sim e^{-\Gamma t} \Big(\left[1 + |r_a|^2 \right] \pm \left[1 - |r_a|^2 \right] \cos(\Delta M t)$$

$$\mp 2\eta_a \text{Im } r_a \sin(\Delta M t) \Big) , \qquad (13.5)$$

where the top sign is for B^0 and the bottom for $\overline{B}{}^0$, η_a is the CP eigenvalue and

$$r_a = (q_B/p_B) \overline{A}_a/A_a . (13.6)$$

The quantity (q_B/p_B) comes from the analogue for B^0 of Eq. (13.1); however, for B^0 the eigenstates have a negligible lifetime difference and are distinguished only by the mass difference ΔM ; also as a result $|q_B/p_B| \approx 1$ so that $\widetilde{\epsilon}_B$ is purely imaginary. A_a (\overline{A}_a) are the decay amplitudes to a for B^0 (\overline{B}^0). If only one quark weak transition contributes to the decay $|\overline{A}_a/A_a| = 1$ so that $|r_a| = 1$ and the $\cos(\Delta Mt)$ term vanishes. The basic goal of the B factories is to observe the asymmetric $\sin(\Delta Mt)$ term. For B^0 (\overline{B}^0) $\to \psi K_s$ from the transition $b \to c\overline{c}s$, one finds in the Standard Model the asymmetry parameter

$$-2\operatorname{Im} r_a = \sin 2\beta \ . \tag{13.7}$$

The asymmetry is given directly in terms of a CKM phase with no hadronic uncertainty and is expected to be between 0.2 and 0.8. For B^0 ($\overline B{}^0$) $\to \pi^+\pi^-$ from the transition $b \to u\overline u d$

$$-2\operatorname{Im} r_a = \sin 2(\beta + \gamma) . \tag{13.8}$$

(This result has some hadronic uncertainty due to penguin contributions, but these should be able to be estimated from other observations.) While either of these asymmetries could be ascribed to $B^0 - \overline{B}{}^0$ mixing $(q_B/p_B \text{ or } \widetilde{\epsilon}_B)$, the difference between the two asymmetries is evidence for direct CP violation. From Eq. (13.6) (with $\overline{A}_a/A_a=1$) it is seen this corresponds to a phase difference between $A_{\psi K_S}$ and $A_{\pi^+\pi^-}$. Thus this is analogous to ϵ' . In the standard phase convention 2β in Eq. (13.7) and (13.8) arises from $B^0 - \overline{B}{}^0$ mixing whereas the 2γ comes from V_{bu} in the transition $b \to u \overline{u} d$.

CP violation in the decay amplitude is also revealed by the $\cos(\Delta Mt)$ in Eq. (13.5) or by a difference in rates of B^+ and B^- to charge-conjugate states. These effects, however, require two contributing amplitudes to the decay (such as a tree amplitude plus a penguin) and also require final-state interaction phases. Predicted effects are very uncertain and are generally small.

For further details, see the notes on CP violation in the K_L^0 , K_S^0 , and B^0 Particle Listings of this Review.

14. CONSTRAINTS ON NEW PHYSICS FROM ELECTROWEAK ANALYSES

This section revised September 1995 by P. Langacker and J. Erler.

Precision electroweak experiments are sensitive to loop effects, allowing a prediction of the top quark mass m_t , constraints on the Higgs mass M_H , and a search for certain types of new physics that have not been directly detected. This article will mainly discuss m_t , M_H , and the effects of exotic particles with masses large compared to M_Z on the gauge boson self-energies. Brief remarks are made on new physics which is not of this type. The effects of m_t and M_H on the radiative corrections are treated exactly to one-loop order. This can in principle be done for other types of new physics, but this necessitates a case-by-case discussion. Instead, the article will discuss in detail only the constraints on particles with heavy masses $M_{\rm new} \gg M_Z$ in an expansion in $M_Z/M_{\rm new}$. In this case, most of the effects on precision measurements can be described by three gauge self-energy parameters S, T, and U, and a $Zb\bar{b}$ vertex correction parameter γ_b .

A large value of $|m_t - m_b|$ breaks vector SU(2) symmetry and significantly affects many precision electroweak observables. The major sensitivity for processes involving light external fermions is through t- and b-quark loop contributions to the W and Z self-energies [1]. Most of the shift in M_W is absorbed into the measured value of the Fermi constant G_F , while the prediction for M_Z ,

$$M_Z = \frac{M_W}{\hat{\rho}^{1/2} \hat{c}_Z} \,, \tag{14.1}$$

decreases rapidly for large m_t . In Eq. (14.1) $\hat{\rho} \simeq 1 + \rho_t$, where

$$\rho_t = \frac{3G_F m_t^2}{8\sqrt{2}\pi^2} \sim 0.0100 \left(\frac{m_t}{180 \text{ GeV}}\right)^2 , \qquad (14.2)$$

and $\widehat{c}_Z = \cos\widehat{\theta}_W(M_Z)$, the cosine of the weak angle in the $\overline{\rm MS}$ scheme evaluated at M_Z [2]. In addition to M_Z itself, neutral current amplitudes and the coefficient of $G_FM_Z^3$ in the expression for Γ_Z are multiplied by $\widehat{\rho}$. There is additional logarithmic m_t dependence in these quantities and in M_W . Vertex and box diagrams also introduce large (quadratic) m_t dependence, which is especially important in quantities involving external b quarks (in order to avoid mixing angle suppressions), such as in the $Z \to b\overline{b}$ partial width or in $B - \overline{B}$ mixing. Finally, in the on-shell renormalization scheme, significant but somewhat artificial m_t dependence is introduced into Z vertices through the definition [2] $s_W^2 \equiv 1 - M_W^2/M_Z^2$.

As discussed in the section on the Standard Model of Electroweak Interactions (Sec. 10) (see especially Fig. 10.1), the consistency of the various observables allows a prediction for m_t . A global fit to all indirect data (see Table 10.5 of the Standard Model Section) yields

$$m_t = 179 \pm 8^{+17}_{-20} \text{ GeV} ,$$
 (14.3)

where the central value is for a Higgs mass $M_H=300$ GeV and the second uncertainty is from varying M_H in the range 60 GeV (-) to 1000 GeV (+). This is in remarkable agreement with the direct determination $m_t=180\pm12$ GeV by the CDF [3] and DØ [4] collaborations. (The indirect prediction is for the pole mass, which corresponds approximately to the kinematic mass determined by CDF and DØ.) A combined fit to both the indirect and direct data yields [2]

$$m_t = 180 \pm 7_{-13}^{+12} \text{ GeV}$$
 (14.4)

As discussed in Ref. 2, the combination of indirect data with the direct CDF and DØ value for m_t allows stringent limits on new physics. In particular, many extensions of the Standard Model are described by the ρ_0 parameter:

$$\rho_0 \equiv M_W^2 / (M_Z^2 \hat{c}_Z^2 \hat{\rho}) , \qquad (14.5)$$

which describes new sources of SU(2) breaking that cannot be accounted for by Higgs doublets or m_t effects. It has previously been difficult to distinguish ρ_0 from $\widehat{\rho} \simeq 1 + \rho_t$ experimentally, though some separation could be done utilizing R_b [5]. Using the direct m_t value as an independent constraint, however, one can calculate $\widehat{\rho}$

and thus obtain the precise value [2] $\rho_0=1.0002\pm0.0013\pm0.0018$, where the second error is from M_H . In Ref. 2, this result was used to constrain the vacuum expectation values of higher-dimensional Higgs representations. It can also be used to constrain other types of new physics. For example, nondegenerate multiplets of heavy fermions or scalars break the vector part of weak SU(2) and lead to a decrease in the value of M_Z/M_W . A nondegenerate SU(2) doublet $\binom{f_1}{f_2}$ yields a positive contribution to ρ_t of [1]

$$\frac{CG_F}{8\sqrt{2}\pi^2}\Delta m^2 , \qquad (14.6)$$

where

$$\Delta m^2 \equiv m_1^2 + m_2^2 - \frac{4m_1^2 m_2^2}{m_1^2 - m_2^2} \ln \frac{m_1}{m_2} \ge (m_1 - m_2)^2 , \qquad (14.7)$$

and C=1 (3) for color singlets (triplets). Thus, in the presence of such multiplets, one has

$$\frac{3G_F}{8\sqrt{2}\pi^2} \sum_i \frac{C_i}{3} \Delta m_i^2 = \rho_0 - 1 , \qquad (14.8)$$

where the sum includes fourth-family quark or lepton doublets, $\binom{t'}{b'}$ or $\binom{E^0}{E^-}$, and scalar doublets such as $\binom{\tilde{t}}{b}$ in supersymmetry (in the absence of L-R mixing). This implies

$$\sum_{i} \frac{C_i}{3} \Delta m_i^2 < (76 \text{ GeV})^2 , (98 \text{ GeV})^2 , (122 \text{ GeV})^2$$
 (14.9)

for $M_H=60,\,300,\,{\rm or}~1000~{\rm GeV}$ at 90% CL.

Nondegenerate multiplets usually imply $\rho_0>1$. Similarly, heavy Z' bosons decrease the prediction for M_Z due to mixing and generally lead to $\rho_0>1$ [6]. On the other hand, additional Higgs doublets which participate in spontaneous symmetry breaking [7], heavy lepton doublets involving Majorana neutrinos [8], and the vacuum expectation values of Higgs triplets or higher-dimensional representations can contribute to ρ_0 with either sign. Allowing for the presence of heavy degenerate chiral multiplets (the S parameter, to be discussed below) affects the determination of ρ_0 from the data, at present leading to a smaller value.

As discussed in the Standard Model of Electroweak Interactions section (Sec. 10), the indirect data exhibit a moderate preference for a smaller Higgs mass. The best fit to m_t as a function of M_H is roughly

$$m_t \sim 180 \pm 7 + 13 \ln \left(\frac{M_H}{300 \text{ GeV}} \right)$$
 (14.10)

including the direct CDF/DØ constraint. The χ^2 for $M_H=60~{\rm GeV}$ is lower by 7.9 than that for $M_H=1000~{\rm GeV}$, implying $M_H\lesssim 320(430)~{\rm GeV}$ at 90(95)% CL. This result is consistent with the minimal supersymmetric extension of the Standard Model, which acts much like the Standard Model with a light Higgs as far as precision experiments are concerned. However, the M_H constraint is largely driven by R_b and A_{LR}^0 , which differ significantly from the Standard Model predictions. In particular, the conclusions for M_H could be invalidated if other new physics modifies the precision observables significantly [9–15].

A number of authors have considered the general effects on neutral current and Z and W-pole observables of various types of heavy (i.e., $M\gg M_Z$) physics which contribute to the W and Z self-energies but which do not have any direct coupling to the ordinary fermions. In addition to nondegenerate multiplets, which break the vector part of weak SU(2), these include heavy degenerate multiplets of chiral fermions which break the axial generators. The effects of one degenerate chiral doublet are small, but in technicolor theories there may be many chiral doublets and therefore significant effects [9].

Such effects can be described by just three parameters, $S,\,T,$ and U at the one (electroweak) loop level. (Three additional parameters

are needed if the new physics scale is comparable to M_Z [16].) T is proportional to the difference between the W and Z self-energies at $Q^2=0$ (i.e., vector SU(2)-breaking), while S (S+U) is associated with the difference between the Z (W) self-energy at $Q^2=M_{Z,W}^2$ and $Q^2=0$ (axial SU(2)-breaking). In the $\overline{\rm MS}$ scheme [10]

$$\alpha(M_Z)T \equiv \frac{\Pi_{WW}^{\text{new}}(0)}{M_W^2} - \frac{\Pi_{ZZ}^{\text{new}}(0)}{M_Z^2}$$

$$\frac{\alpha(M_Z)}{4\hat{s}^2\hat{c}_Z^2}S \equiv \frac{\Pi_{ZZ}^{\text{new}}(M_Z^2) - \Pi_{ZZ}^{\text{new}}(0)}{M_Z^2}$$

$$\frac{\alpha(M_Z)}{4\hat{s}^2}(S+U) \equiv \frac{\Pi_{WW}^{\text{new}}(M_W^2) - \Pi_{WW}^{\text{new}}(0)}{M_W^2} , \qquad (14.11)$$

where Π_{WW}^{new} and Π_{ZZ}^{new} are respectively the contributions of the new physics to the W and Z self-energies, $\widehat{s}_Z^2 = \sin^2 \widehat{\theta}_W(M_Z)$, $\widehat{c}_Z^2 = 1 - \widehat{s}_Z^2$, and $\alpha(M_Z) \sim 1/129$ [2] is the running coupling evaluated at M_Z . S, T, and U are defined with a factor of α removed, so that they are expected to be of order unity in the presence of new physics. S, T, and U are related to other parameters ($\widehat{\epsilon}_i$, h_i , S_i) defined in [10–12] by

$$T = h_V = \hat{\epsilon}_1/\alpha$$

$$S = h_{AZ} = S_Z = 4\hat{s}_Z^2 \hat{\epsilon}_3/\alpha$$

$$U = h_{AW} - h_{AZ} = S_W - S_Z = -4\hat{s}_Z^2 \hat{\epsilon}_2/\alpha . \tag{14.12}$$

A heavy nondegenerate multiplet of fermions or scalars contributes positively to T as

$$\rho_0 = \frac{1}{1 - \alpha T} \simeq 1 + \alpha T \,\,, \tag{14.13}$$

where ρ_0 is given in Eq. (14.8). If there are non-doublet Higgs representations, their vacuum expectation values also contribute to ρ_0 . The effects of such nonstandard Higgs representations cannot be separated from heavy nondegenerate multiplets unless the new physics has other consequences, such as vertex corrections. Most of the original papers defined T to include the effects of loops only. However, we will redefine T to include all new sources of SU(2) breaking, including nonstandard Higgs, so that T and ρ_0 are equivalent by Eq. (14.13).

A multiplet of heavy degenerate chiral fermions yields

$$S = C \sum_{i} \left(t_{3L}(i) - t_{3R}(i) \right)^2 / 3\pi , \qquad (14.14)$$

where $t_{3L,R}(i)$ is the third component of weak isospin of the left-(right-) handed component of fermion i and C is the number of colors. For example, a heavy degenerate ordinary or mirror family would contribute $2/3\pi$ to S. In technicolor models with QCD-like dynamics, one expects [9] $S \sim 0.45$ for an isodoublet of technifermions, assuming N_{TC} =4 technicolors, while $S\sim 1.62$ for a full technique reation with N_{TC} =4; T is harder to estimate because it is model dependent. In these examples one has $S \geq 0$. However, the QCD-like models are excluded on other grounds (flavor-changing neutral currents, and too-light quarks and pseudo-Goldstone bosons [17]). In particular, these estimates do not apply to models of walking technicolor [17], for which S can be smaller or even negative [18]. Other situations in which S < 0, such as loops involving scalars or Majorana particles, are also possible [19]. Supersymmetric extensions of the Standard Model generally give very small effects [20]. Most simple types of new physics yield U = 0, although there are counter-examples, such as the effects of anomalous triple-gauge vertices [12].

It is also possible to parametrize the effects of large $m_t \gg M_Z$ (except for the $b\bar{b}$ vertex) or $M_H \gg M_Z$ in terms of $S,\ T$, and U. If one takes $m_t = m_t^{\rm ref}, M_H = M_H^{\rm ref}$ as a reference point, then other values of m_t and M_H can be expressed for large $m_t,\ M_H$ as [11]

$$\Delta T = \frac{\rho_t(m_t) - \rho_t(m_t^{\text{ref}})}{\alpha}$$

$$-\frac{3G_F}{4\sqrt{2}\alpha\pi^2}(M_Z^2 - M_W^2)\ln(M_H/M_H^{\text{ref}})$$

$$\Delta S = c_S \ln(m_t/m_t^{\text{ref}}) + \frac{1}{6\pi}\ln(M_H/M_H^{\text{ref}})$$

$$\Delta U = c_U \ln(m_t/m_t^{\text{ref}}) , \qquad (14.15)$$

where the coefficients c_S and c_U depend on the renormalization scheme. Prior to the direct obsevation of the t quark it was difficult to separate the effects of m_t and M_H from the new physics contributions to S, T, and U. Most authors therefore picked fixed arbitrary reference values for m_t and M_H , so that the values of S, T, U extracted from the data included both new physics and ΔS , ΔT , ΔU . Now that m_t is known independently this is no longer necessary [21]. In the following, S, T, and U will represent the contributions of new physics only. The full m_t and M_H dependence of all observables will be included in the fits separately, with the uncertainties in m_t and M_H appearing as uncertainties in the extracted S, T, U.

The Standard Model expressions for observables are replaced by

$$\begin{split} M_Z^2 &= M_{Z0}^2 \frac{1 - \alpha T}{\rho_0} \frac{1}{1 - G_F M_{Z0}^2 S / 2\sqrt{2}\pi} \\ M_W^2 &= M_{W0}^2 \frac{1}{1 - G_F M_{W0}^2 (S + U) / 2\sqrt{2}\pi} \ , \end{split} \tag{14.16}$$

where M_{Z0} and M_{W0} are the Standard Model expressions (as functions of m_t and M_H) in the $\overline{\rm MS}$ scheme. Furthermore,

$$\Gamma_Z = \frac{\rho_0}{1 - \alpha T} M_Z^3 \beta_Z$$

$$\Gamma_W = M_W^3 \beta_W$$

$$A_i = \frac{\rho_0}{1 - \alpha T} A_{i0} , \qquad (14.17)$$

where β_Z and β_W are the Standard Model expressions for the reduced widths Γ_{Z0}/M_{Z0}^3 and Γ_{W0}/M_{W0}^3 , M_Z and M_W are the physical masses, and A_i (A_{i0}) is a neutral current amplitude (in the Standard Model).

The $Z\to b\bar b$ vertex is sensitive to certain types of new physics which primarily couple to heavy families. It is useful to introduce an additional parameter γ_b by [22]

$$\Gamma(Z \to b\overline{b}) = \Gamma^0(Z \to b\overline{b})(1 + \gamma_b) , \qquad (14.18)$$

where Γ^0 is the Standard Model expression (or the expression modified by S, T, and U). Experimentally, $R_b \equiv \Gamma(Z \to b\bar{b})/\Gamma(\text{had})$ is more than 3σ above the Standard Model expectations, favoring a positive γ_b . (See the discussion in Ref. 2.) Extended technicolor interactions generally yield negative values of γ_b of a few percent [23], although it is possible to obtain a positive γ_b in models for which the extended technicolor group does not commute with the electroweak gauge group [24] or for which diagonal interactions related to the extended technicolor dominate [25]. Topcolor and topcolor-assisted technicolor models do not generally give a significant contribution to γ_b because the extended technicolor contribution to m_t is small [26]. Supersymmetry can yield (typically small) contributions of either sign [27,28].

The data allow a simultaneous determination of \widehat{s}_Z^2 (e.g., from the Z-pole asymmetries), S (from M_Z), U (from M_W), T (e.g., from the Z-decay widths), α_s (from $\Gamma(Z \to \text{had})/\Gamma(\ell \bar{\ell})$, m_t (from CDF and DØ), and γ_b (from R_b) with little correlation except between α_s and γ_b .

$$S = -0.28 \pm 0.19^{+0.08}_{+0.17}$$

$$T = -0.20 \pm 0.26^{+0.17}_{-0.12}$$

$$U = -0.31 \pm 0.54$$

$$\gamma_b = 0.032 \pm 0.010 , \qquad (14.19)$$

and $\hat{s}_Z^2 = 0.2311 \pm 0.0003$, $\alpha_s = 0.103 \pm 0.008$, $m_t = 181 \pm 12$ GeV, where the first uncertainties are from the inputs. The central values assume $M_H = 300$ GeV, and the second uncertainty, when given, is the change for $M_H = 1000$ GeV (upper) and 60 GeV (lower). S, T, and U, which are due to new physics only, are all consistent with the Standard Model value of zero at or near the 1σ level, although there is a slight tendency for negative S and T. Using Eq. (14.13) the value of ρ_0 corresponding to T is $0.9985 \pm 0.0019_{-0.0009}^{+0.0012}$. The values of the $\widehat{\epsilon}$ parameters defined in Eq. (14.12) are

$$\widehat{\epsilon}_3 = -0.0022 \pm 0.0015^{-0.0007}_{+0.0013}$$
,
 $\widehat{\epsilon}_1 = -0.0015 \pm 0.0019^{+0.0013}_{-0.0008}$,
 $\widehat{\epsilon}_2 = +0.0024 \pm 0.0033$. (14.20)

There is a strong correlation between γ_b and the predicted α_s , just as in the model with S=T=U=0 [2,21]. For $\gamma_b=0$ one obtains $\alpha_s=0.122\pm0.005$ and $T=-0.04\pm0.25^{+0.17}_{-0.11}$, with little change in the other parameters. The allowed region in S-T is shown in Fig. 14.1. From Eq. (14.19) one obtains S<0.12 (0.21) and T<0.29 (0.38) at 90 (95)% CL. If one requires the constraint $S\geq0$ (as in QCD-like technicolor models) then S<0.25 (0.30). Allowing arbitrary S, only one heavy generation of ordinary fermions is allowed at 95% CL. The favored value of S is problematic for simple technicolor models with many techni-doublets and QCD-like dynamics, as is the value of γ_b . Although S is consistent with zero, the electroweak asymmetries, especially the SLD left-right asymmetry, favor S<0. The simplest origin of S<0 would probably be an additional heavy Z' boson [6], which could mimic S<0. Similarly, there is a slight indication of negative T, while, as discussed above, nondegenerate scalar or fermion multiplets generally predict T>0.

There is no simple parametrization that is powerful enough to describe the effects of every type of new physics on every possible observable. The S, T, and U formalism describes many types of heavy physics which affect only the gauge self-energies, and it can be applied to all precision observables. However, new physics which couples directly to ordinary fermions, such as heavy Z' bosons or mixing with exotic fermions cannot be fully parametrized in the S, T. and U framework. It is convenient to treat these types of new physics by parametrizations that are specialized to that particular class of theories (e.g., extra Z' bosons), or to consider specific models (which might contain, e.g., Z' bosons and exotic fermions with correlated parameters). Constraints on various types of new physics are reviewed in [29,30,31]. Fits to models with technicolor, extended technicolor, and supersymmetry are described respectively in [32], [24], and [33]. Versions of these which allow $\gamma_b > 0$ can, for that reason, give better fits than the Standard Model. An alternate formalism [34] defines parameters, ϵ_1 , ϵ_2 , ϵ_3 , ϵ_b in terms of the specific observables M_W/M_Z , the leptonic Z width $\Gamma_{\ell\ell}$, the forward-backward asymmetry [2] at the Z pole $A_{FB}^{(0,\ell)}$, and R_b . The definitions coincide with those for $\widehat{\epsilon}_i$ in Eqs. (14.11) and (14.12) for physics which affects gauge self-energies only, but the ϵ 's now parametrize arbitrary types of new physics and can also incorporate all of the effects of m_t and M_H on the four basic observables. However, the ϵ 's are not related to other observables unless additional model-dependent assumptions are made. Another approach [35,36] parametrizes new physics in terms of gauge-invariant sets of operators. It is especially powerful in studying the effects of new physics on nonabelian gauge vertices. The most general approach introduces deviation vectors [29]. Each type of new physics defines a deviation vector, the components of which are the deviations of each observable from its Standard Model prediction, normalized to the experimental uncertainty. The length (direction) of the vector represents the strength (type) of new physics.

15. BIG-BANG COSMOLOGY

Revised November 1993 by K.A. Olive.

At early times, and today on a sufficiently large scale, our Universe is very nearly homogeneous and isotropic. The most general space-time metric for a homogeneous, isotropic space is the Friedmann-Robertson-Walker metric (with c=1) [1,2,3]:

$$ds^{2} = dt^{2} - R^{2}(t) \left[\frac{dr^{2}}{1 - \kappa r^{2}} + r^{2} (d\theta^{2} + \sin^{2}\theta \, d\phi^{2}) \right] . \tag{15.1}$$

R(t) is a scale factor for distances in comoving coordinates. With appropriate rescaling of the corrdinates, κ can be chosen to be +1, -1, or 0, corresponding to closed, open, or spatially flat geometries. Einstein's equations lead to the Friedmann equation

$$H^2 \equiv \left(\frac{\dot{R}}{R}\right)^2 = \frac{8\pi G_N \rho}{3} - \frac{\kappa}{R^2} + \frac{\Lambda}{3} ,$$
 (15.2)

as well as to

$$\frac{\ddot{R}}{R} = \frac{\Lambda}{3} - \frac{4\pi G_N}{3} \ (\rho + 3p) \ , \tag{15.3}$$

where H(t) is the Hubble parameter, ρ is the total mass-energy density, p is the isotropic pressure, and Λ is the cosmological constant. (For limits on Λ , see the Table of Astrophysical Constants; we will assume here $\Lambda=0$.) The Friedmann equation serves to define the density parameter Ω_0 (subscript 0 indicates present-day values):

$$\kappa/R_0^2 = H_0^2(\Omega_0 - 1) , \qquad \Omega_0 = \rho_0/\rho_c ;$$
 (15.4)

and the critical density is defined as

$$\rho_c \equiv \frac{3H^2}{8\pi G_N} = 1.88 \times 10^{-29} \, h^2 \, \text{g cm}^{-3} \,,$$
(15.5)

with

$$H_0 = 100 h_0 \text{ km s}^{-1} \text{ Mpc}^{-1} = h_0/(9.78 \text{ Gyr}).$$
 (15.6)

Observational bounds give $0.4 < h_0 < 1$. The three curvature signatures $\kappa = +1, -1$, and 0 correspond to $\Omega_0 > 1$, < 1, and = 1. Knowledge of Ω_0 is even poorer than that of h_0 . Luminous matter (stars and associated material) contribute $\Omega_{lum} \leq 0.01$. There is no lack of evidence for copious amounts of dark matter: rotation curves of spiral galaxies, virial estimates of cluster masses, gravitational lensing by clusters and individual galaxies, and so on. The minimum amount of dark matter required to explain the flat rotation curves of spiral galaxies only amounts to $\Omega_0 \sim 0.1$, while estimates for Ω_0 based upon cluster virial masses suggests $\Omega_0 \sim 0.2 - 0.4$. The highest estimates for the mass density come from studies of the peculiar motions of galaxies (including our own); estimates for Ω_0 obtained by relating peculiar velocity measurements to the distribution galaxies within a few hundred Mpc approach unity. A conservative range for the mass density is: $0.1 \le \Omega_0 \le 2$. The excess of Ω_0 over Ω_{lum} leads to the inference that most of the matter in the Universe is nonluminous dark matter.

In an expanding universe, the wavelength of light emitted from a distant source is shifted towards the red. The redshift z is defined such that 1+z is the ratio of the detected wavelength (λ) to emitted (laboratory) wavelength (λ_c) of some electromagnetic spectral feature. It follows from the metric given in Eq. (15.1) that

$$1 + z = \lambda/\lambda_{\rm e} = R_0/R_{\rm e} \tag{15.7}$$

where $R_{\rm c}$ is the value of the scale factor at the time the light was emitted. For light emitted in the not too distant past, one can expand $R_{\rm c}$ and write $R_{\rm c} \simeq R_0 + (t_{\rm c} - t_0) \dot{R}_0$. For small (compared to H_0^{-1}) $\Delta t = (t_{\rm c} - t_0)$, Eq. (15.7) takes the form of Hubble's law

$$z \approx \Delta t \frac{\dot{R}_0}{R_0} \approx \ell H_0 , \qquad (15.8)$$

where ℓ is the distance to the source.

Energy conservation implies that

$$\dot{\rho} = -3(\dot{R}/R)(\rho + p) ,$$
 (15.9)

so that for a matter-dominated (p=0) universe $\rho \propto R^{-3}$, while for a radiation-dominated $(p=\rho/3)$ universe $\rho \propto R^{-4}$. Thus the less singular curvature term κ/R^2 in the Friedmann equation can be neglected at early times when R is small. If the Universe expands adiabatically, the entropy per comoving volume $(\equiv R^3 s)$ is constant, where the entropy density is $s=(\rho+p)/T$ and T is temperature. The energy density of radiation can be expressed (with $\hbar=c=1$) as

$$\rho_r = \frac{\pi^2}{30} N(T)(kT)^4 , \qquad (15.10)$$

where N(T) counts the effectively massless degrees of freedom of bosons and fermions:

$$N(T) = \sum_{R} g_{B} + \frac{7}{8} \sum_{F} g_{F} . \tag{15.11}$$

For example, for $m_{\mu} > kT > m_e$, $N(T) = g_{\gamma} + 7/8 \, (g_e + 3g_{\nu}) = 2 + 7/8 \, [4 + 3(2)] = 43/4$. For $m_{\pi} > kT > m_{\mu}$, N(T) = 57/4. At temperatures less than about 1 MeV, neutrinos have decoupled from the thermal background, i.e., the weak interaction rates are no longer fast enough compared with the expansion rate to keep neutrinos in equilibrium with the remaining thermal bath consisting of γ , e^{\pm} . Furthermore, at temperatures $kT < m_e$, by entropy conservation, the ratio of the neutrino temperature to the photon temperature is given by $(T_{\nu}/T_{\gamma})^3 = g_{\gamma}/(g_{\gamma} + \frac{7}{8}g_e) = 4/11$.

In the early Universe when $\rho \approx \rho_r$, then $\dot{R} \propto 1/R$, so that $R \propto t^{1/2}$ and $Ht \to 1/2$ as $t \to 0$. The time-temperature relationship at very early times can then be found from the above equations:

$$t = \frac{2.42}{\sqrt{N(T)}} \left(\frac{1 \text{ MeV}}{kT}\right)^2 \text{ sec} .$$
 (15.12)

At later times, since the energy density in radiation falls off as R^{-4} and the energy density in non-relativistic matter falls off as R^{-3} , the Universe eventually became matter dominated. The epoch of matter-radiation density equality is determined by equating the matter density at $t_{\rm eq}$, $\rho_m = \Omega_0 \rho_c (R_0/R_{\rm eq})^3$ to the radiation density, $\rho_r = (\pi^2/30)[2 + (21/4)(4/11)^{4/3}](kT_0)^4(R_0/R_{\rm eq})^4$ where T_0 is the present temperature of the microwave background (see below). Solving for $(R_0/R_{\rm eq}) = 1 + z_{\rm eq}$ gives

$$z_{\text{eq}} + 1 = \Omega_0 h_0^2 / 4.2 \times 10^{-5} = 2.4 \times 10^4 \,\Omega_0 h_0^2 ;$$

$$kT_{\text{eq}} = 5.6 \,\Omega_0 h_0^2 \,\text{eV} ;$$

$$t_{\text{eq}} \approx 0.39 (\Omega_0 H_0^2)^{-1/2} (1 + z_{\text{eq}})^{-3/2}$$

$$= 3.2 \times 10^{10} (\Omega_0 h_0^2)^{-2} \,\text{sec} . \tag{15.13}$$

Prior to this epoch the density was dominated by radiation (relativistic particles; see Eq. (15.10)), and at later epochs matter density dominated. Atoms formed at $z\approx 1300$, and by $z_{\rm dec}\approx 1100$ the free electron density was low enough that space became essentially transparent to photons and matter and radiation were decoupled. These are the photons observed in the microwave background today.

The age of the Universe today, t_0 , is related to both the Hubble parameter and the value of Ω_0 (still assuming that $\Lambda=0$). In the Standard Model, $t_0\gg t_{\rm eq}$ and we can write

$$t_0 = H_0^{-1} \int_0^1 \left(1 - \Omega_0 + \Omega_0 x^{-1} \right)^{-1/2} dx . \tag{15.14}$$

Constraints on t_0 yield constraints on the combination $\Omega_0 h_0^2$. For example, $t_0 \ge 13 \times 10^9$ yr implies that $\Omega_0 h_0^2 \le 0.25$ for $h_0 \ge 0.5$,

or $\Omega_0 h_0^2 \leq 0.45$ for $h_0 \geq 0.4$, while $t_0 \geq 10 \times 10^9$ yr implies that $\Omega_0 h_0^2 \leq 0.8$ for $h_0 \geq 0.5$, or $\Omega_0 h_0^2 \leq 1.1$ for $h_0 \geq 0.4$.

The present temperature of the microwave background is $T_0=2.726\pm0.005$ K as measured by COBE [4], and the number density of photons $n_{\gamma}=(2\zeta(3)/\pi^2)(kT_0)^3\approx411$ cm⁻³. The energy density in photons (for which $g_{\gamma}=2$) is $\rho_{\gamma}=(\pi^2/15)(kT_0)^4$. At the present epoch, $\rho_{\gamma}=4.65\times10^{-34}$ g cm⁻³=0.26 eV cm⁻³. For nonrelativistic matter (such as baryons) today, the energy density is $\rho_B=m_Bn_B$ with $n_B\propto R^{-3}$, so that for most of the history of the Universe n_B/s is constant. Today, the entropy density is related to the photon density by $s=(4/3)(\pi^2/30)[2+(21/4)(4/11)](kT_0)^3=7.0\,n_{\gamma}$. Big Bang nucleosynthesis calculations limit $\eta=n_B/n_{\gamma}$ to $2.8\times10^{-10} \le \eta \le 4.0\times10^{-10}$. The parameter η is also related to the portion of Ω in baryons

$$\Omega_B = 3.66 \times 10^7 \eta \ h_0^{-2} (T_0/2.726 \ \text{K})^3 ,$$
 (15.15)

so that $0.010 < \Omega_B \ h_0^2 < 0.015$, and hence the Universe cannot be closed by baryons.

16. BIG-BANG NUCLEOSYNTHESIS

Written July 1995 by K.A. Olive and D.N. Schramm.

Among the successes of the standard big-bang model is the agreement between the predictions of big-bang nucleosynthesis (BBN) for the abundances of the light elements, D, $^3{\rm He}$, $^4{\rm He}$, and $^7{\rm Li}$, and the primordial abundances inferred from observational data (see [1–3] for a more complete discussion). These abundances span some nine orders of magnitude: $^4{\rm He}$ has an abundance by number relative to hydrogen of about 0.08 (accounting for about 25% of the baryonic mass), while $^7{\rm Li}$, the least abundant of the elements with a big-bang origin, has a abundance by number relative to hydrogen of about $\sim 10^{-10}$.

16.1. Big-bang nucleosynthesis theory

The BBN theory matches the observationally determined abundances with a single well-defined parameter, the baryon-to-photon ratio, η . All the light-element abundances can be explained with η in the relatively narrow range $(2.8\text{-}4.5)\times 10^{-10}$, or $\eta_{10}\equiv \eta\times 10^{10}=2.8\text{-}4.5$. (When possible systematic errors are allowed to take extreme values, the range becomes $\eta_{10}=1.5\text{-}6.3$ [4]. We shall always quote this extreme range parenthetically following the best range.) Equivalently, this range can be expressed as the allowed range for the baryon mass density, $\rho_B=1.9\text{-}3.1$ (1.0–4.3) $\times 10^{-31}$ g cm⁻³, and can be converted to the fraction of the critical density, Ω .

The synthesis of the light elements was affected by conditions in the early Universe at temperatures $T\lesssim 1$ MeV, corresponding to an age as early as 1 s. At somewhat higher temperatures, weak-interaction rates were in equilibrium, thus fixing the ratio of the neutron and proton number densities. At $T\gg 1$ MeV, $n/p\approx 1$, since the ratio was given approximately by the Boltzmann factor, $n/p\approx e^{-Q/T}$, where Q is the neutron-proton mass difference. As the temperature fell, the Universe approached the point ("freeze-out") where the weak-interaction rates were no longer fast enough to maintain equilibrium. The final abundance of ⁴He is very sensitive to the n/p ratio at freeze-out.

The nucleosynthesis chain begins with the formation of deuterium in the process $pn \to D\gamma$. However, photo-dissociation by the high number density of photons $(n_\gamma/n_B = \eta^{-1} \sim 10^{10})$ delays production of deuterium (and other complex nuclei) well past the point where T reaches the binding energy of deuterium, $E_B = 2.2$ MeV. (The average photon energy in a blackbody is $\overline{E}_\gamma \approx 2.7$ T.) When the quantity $\eta^{-1} \exp(-E_B/T)$ reaches about 1 (at $T \approx 0.1$ MeV), the photo-dissociation rate finally falls below the nuclear production rate.

The 25% fraction of mass in $^4\mathrm{He}$ due to BBN is easily estimated by counting the number of neutrons present when nucleosynthesis begins. When the weak-interaction rates freeze-out at about $T\approx 0.8$ MeV, the n-to-p ratio is about 1/6. When free-neutron decays prior to deuterium formation are taken into account, the ratio drops to $n/p\lesssim 1/7$. Then simple counting yields a primordial $^4\mathrm{He}$ mass fraction

$$Y_p = \frac{2(n/p)}{1 + n/p} \lesssim 0.25 \ . \tag{16.1}$$

In the Standard Model, the ⁴He mass fraction depends primarily on the baryon-to-photon ratio η , as it is this quantity that determines when nucleosynthesis via deuterium production may begin. But because the n/p ratio depends only weakly on η , the ⁴He mass fraction is relatively flat as a function of η . The effect of the uncertainty in the neutron half-life, $\tau_n = 887 \pm 2$ s, is small. Lesser amounts of the other light elements are produced: D and ³He at the level of a few times 10^{-5} by number relative to H, and ⁷Li/H at the level of about 10^{-10} , when η is in the range $1 - 10 \times 10^{-10}$.

When we go beyond the Standard Model, the ⁴He abundance is very sensitive to changes in the expansion rate, which can be related to the effective number of neutrino flavors. This will be discussed below

The calculated abundances of the light elements are shown in Fig. 16.1 as a function of η_{10} . The curves for the ⁴He mass fraction, Y_p , bracket the range based on the uncertainty of the neutron mean-life, $\tau_n=887\pm2$ s. The spread in the ⁷Li curves is due to

the 1σ uncertainties in nuclear cross sections leading to $^7\mathrm{Li}$ and $^7\mathrm{Be}$ which subsequently decays to $^7\mathrm{Li}$ [4,5,6]. The uncertainties in the D and $^3\mathrm{He}$ predictions are small and have been neglected here. The boxes show to the observed abundances, discussed below. Since the observational boxes line up on top of each other, there is an overall agreement between theory and observations for η_{10} in the range 2.8–4.5 (1.5–6.3).

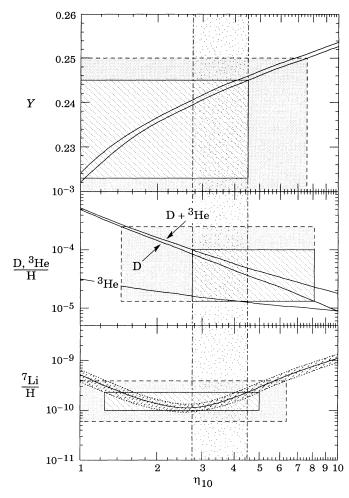

Figure 16.1: The abundances of D, ³He, ⁴He and ⁷Li as predicted by the standard model of big-bang nucleosynthesis. Also shown by a series of boxes is the comparison between these predictions and the observational determination of the light element abundances. See text for details.

16.2. Observations

Because stars produce helium as well as heavier elements, one must search for primordial helium in regions where stellar processing has been minimal, *i.e.*, in regions where abundances of elements such as carbon, nitrogen, and oxygen are very low. There are extensive compilations of observed abundances of $^4{\rm He}$, N, and O in many different extra-galactic regions of ionized H [7,8,9]. Extrapolating the $^4{\rm He}$ abundances from the data leads to a observational estimate for Y_p of [10,11]

$$Y_p = 0.234 \pm 0.003 \pm 0.005$$
 (16.2)

(Here and elsewhere, the first error is the statistical standard deviation, and the second systematic.) The large box in Fig. 16.1 bracketing the

110

⁴He curves covers the range 0.223 to 0.245, where the half height is conservatively given as twice the statistical error plus the systematic error. There has been some debate on the size of systematic errors [4] and the dashed box is obtained using a larger systematic error of 0.01.

Observations for deuterium and ³He abundances present larger problems. All deuterium is primordial [12], but some of the primordial deuterium has been destroyed. Thus, as can be seen in the figure, the present deuterium abundance gives an upper limit to η . However, to get more information requires either an understanding of galactic chemical evolution of deuterium or a direct measurement of primordial deuterium. Even more problematical is ³He: Not only is primordial ³He destroyed in stars but it is very likely that low-mass stars are net producers of ³He. Neither the galactic chemical evolution of ³He nor the production of ³He in stars is well understood.

It appears that D/H has decreased over the age of the galaxy. Samples obtained deep inside meteorites provide measurements of the true (pre)-solar system abundance of ³He, while measurements on meteoritic near-surface samples, the solar wind, and lunar soil samples also contain ³He converted from deuterium in the early pre-main-sequence stage of the sun. The best current values are [13]

$$\left(\frac{D + {}^{3}\text{He}}{H}\right)_{\odot} = (4.1 \pm 1.0) \times 10^{-5} ,$$

$$\left(\frac{{}^{3}\text{He}}{H}\right)_{\odot} = (1.5 \pm 0.3) \times 10^{-5} .$$
(16.3)

The difference between these, D/H $\approx (2.6 \pm 1.0) \times 10^{-5}$, is the pre-solar D abundance.

On the other hand, the present interstellar-medium abundance of D/H is [14]

$$D/H = 1.60 \pm 0.09_{-0.10}^{+0.05} \times 10^{-5} . {(16.4)}$$

It is this lowest value of D/H that provides the most robust upper bound on η , since D is only destroyed. It is shown (decreased by $2\sigma_{\rm stat} + \sigma_{\rm syst}$) as the lower side of the D and ³He box in Fig. 16.1. If η_{10} is in the range 2.8–4.5 (1.5–6.3) then the primordial abundance of D/H is between 3.6–8 (2–25) ×10⁻⁵, and it would appear that significant destruction of deuterium has occurred. The upper side of the box in Fig. 16.1 comes from the upper limit on (D + ³He) $_{\odot}$ under the assumption that at least 25% of a star's initial D + ³He is returned to the interstellar medium [15].

Deuterium may have been detected in high-redshift, low-metallicity quasar absorption systems [16,17,18]. These measured abundances should represent the primordial value, but, they are not entirely consistent: One [16] gives D/H $\approx 1.9 - 2.5 \times 10^{-4}$ while the other [17] gives $D/H \approx 1-2 \times 10^{-5}$. Most recently, measurements in three absorption systems show consistent values of D/H around 10^{-4.0±0.25} [18] and corresponds to a value of η in good agreement with that discussed in the previous section. The upper limit on D/H from the first observation is shown by the dashed box in Fig. 16.1. As one can see, the corresponding value of Y_p (at the same value of η as inferred by the observation of a high D/H) is in excellent agreement with the data. ⁷Li is also acceptable at this value as well. However, due to the still somewhat preliminary status of this observation, it is premature to use it to fix the primordial abundance. A high value for the D abundance would require an even greater degree of D destruction over the age of the galaxy. The lower measurement for D/H is problematic for both ⁴He and ⁷Li and requires that systematics all work in the same direction to give a marginal overlap with this data.

Finally, we turn to $^7\mathrm{Li}$. In old, hot, population-II stars, $^7\mathrm{Li}$ is found to have a very nearly uniform abundance. For stars with a surface temperature T > 5500 K and a metallicity less than about 1/20th solar (so that effects such as stellar convection may not be important), the abundances show little or no dispersion beyond that consistent with the errors of individual measurements. Much data has been obtained recently from a variety of sources, and the best estimate for the mean $^7\mathrm{Li}$ abundance and its statistical uncertainty in halo stars is [19](the estimate of the systematic uncertainty discussed below is our own)

$$\text{Li/H} = (1.6 \pm 0.1^{+0.4+1.6}_{-0.3-0.5}) \times 10^{-10}$$
 (16.5)

The first error is statistical, and the second is a systematic uncertainty that covers the range of abundances derived by various methods. The box in Fig. 16.1 corresponds to these errors (as before, with a half height of $2\sigma_{\rm stat} + \sigma_{\rm syst}$). The third set of errors in Eq. (16.5) accounts for the possibility that as much as half of the primordial ⁷Li has been destroyed in stars, and that as much as 30% of the observed ⁷Li was produced in cosmic ray collisions rather than in the Big Bang. These uncertainties are shown by the dashed box in Fig. 16.1. Observations of ⁶Li, Be, and B help constrain the degree to which these effects play a role [20,21,22].

16.3. A consistent value for η

For the standard model of BBN to be deemed successful, theory and observation of the light element abundances must agree using a single value of η . We summarize the constraints on η from each of the light elements. From the ⁴He mass fraction, $Y_p < 0.240$ (0.245–0.250), we have $\eta_{10} < 2.9$ (4.5–7.6) as a 2σ upper limit (the highest values use possible systematic errors up to their extreme range). Because of the sensitivity to the assumed upper limit on γ , the upper limit on η from D/H, is still of value. From D/H > 1.3×10^{-5} , we have $\eta_{10} < 8.1$.

The lower limit on η_{10} comes from the upper limit on D + 3 He and is $\eta_{10} \gtrsim 2.8$ if one ignores 3 He production. We stress, however, that the upper limit on D + 3 He depends critically on models of galactic chemical evolution, which are far from being understood, and that one of the two measurements of D/H in quasar absorption systems indicates that $\eta_{10} \sim 1.5$.

Finally, ^{7}Li allows a broad range for η_{10} consistent with the other elements. When uncertainties in the reaction rates and systematic uncertainties in the observed abundances are both taken into account, ^{7}Li allows values of η_{10} between 1.3–5.0 (1–6.3). The resulting overall consistent range for η_{10} becomes 2.8–4.5 (1.5–6.3). These bounds on η_{10} constrain the fraction of critical density in baryons, Ω_B , to be

$$0.010 < \Omega_B h_0^2 < 0.016 \ (0.005 < \Omega_B h_0^2 < 0.023)$$
 (16.6)

for a Hubble parameter, h_0 , between 0.4 and 1.0. The corresponding range for Ω_B is 0.01–0.10 (0.005–0.14).

16.4. Beyond the Standard Model

Limits on particle physics beyond the Standard Model come mainly from the observational bounds on the $^4\mathrm{He}$ abundance. As discussed earlier, the neutron-to-proton ratio is fixed by its equilibrium value at the freeze-out of the weak-interaction rates at a temperature $T_f \sim 1$ MeV, with corrections for free neutron decay. Furthermore, freeze-out is determined by the competition between the weak-interaction rates and the expansion rate of the Universe,

$$G_F^2 T_f^5 \sim \Gamma_{\text{wk}}(T_f) = H(T_f) \sim \sqrt{G_N N(T_f)} T_f^2$$
, (16.7)

where $N(T_f)$ counts the total (equivalent) number of relativistic particle species. The presence of additional neutrino flavors (or of any other relativistic species) at the time of nucleosynthesis increases the energy density of the Universe and hence the expansion rate, leading to a larger value of T_f , n/p, and ultimately Y_p . It is clear that just as one can place limits [23] on N, any changes in the weak or gravitational coupling constants can be similarly constrained.

In the Standard Model, the number of particle species can be written as $N=5.5+\frac{7}{4}N_{\nu}$ at $T_f=1$ MeV; 5.5 accounts for photons and e^{\pm} ; and N_{ν} is the number of light neutrino flavors. The helium curves in Fig. 16.1 were computed assuming $N_{\nu}=3$, and the computed ⁴He abundance scales roughly as $\Delta Y_{\rm BBN}\approx 0.012-0.014$ ΔN_{ν} . Clearly the central value for N_{ν} from BBN will depend on η . If the best value for the observed primordial ⁴He abundance is 0.234, then, for $\eta_{10}\sim 1.7$, the central value for N_{ν} is very close to 3. For $\eta_{10}>2.8$ the central value for N_{ν} is less than 2.5. However, because of the uncertainties in the abundances, and thus in η , the upper limit on N_{ν} is more important here than the central value of N_{ν} . A straightforward propagation of errors leads to a 2σ upper limit of about 3.1 (3.5) on N_{ν} when systematic errors are included [10,24]. Other prescriptions,

which involve renormalization of the probability distributions when the central value of N_{ν} falls below 3, give even higher upper limits to N_{ν} [25].

The limits on N_{ν} can be translated into limits on other types of particles or particle masses that would affect the expansion rate of the Universe just prior to nucleosynthesis. In some cases, it is the interaction strengths of new particles which are constrained. Particles with less than full weak strength interactions contribute less to the energy density than particles that remain in equilibrium up to the time of nucleosynthesis [26].

We close with a simple example. Suppose there exist three right-handed neutrinos with only right-handed interactions of strength $G_R < G_F$. The standard left-handed neutrinos are no longer in equilibrium at temperatures below ~ 1 MeV. Particles with weaker interactions decouple at higher temperatures, and their number density ($\propto T^3$) relative to neutrinos is reduced by the annihilations of particles more massive than 1 MeV. If we use the upper bound N_{ν} < 3.1, then the three right-handed neutrinos must have a temperature $3(T_{\nu_R}/T_{\nu_L})^4 < 0.1$. Since the temperature of the decoupled ν_R 's is R. The property conservation, $T_{\nu_R}/T_{\nu_L} = [(43/4)/N(T_f)]^{1/3} < 0.4$, where T_f is the freeze-out temperature of the ν_R 's. Thus $N(T_f) > 100$ and decoupling must have occurred at $T_f > M_W$ (since in the Standard Model, $N(T > M_W) = 106.75$). Finally, the decoupling temperature is related to G_R by $(G_R/G_F)^2 \sim (T_f/3 \text{ MeV})^{-3}$, where 3 MeV corresponds to the decoupling temperature for ν_L . This yields a limit $G_R \lesssim 10^{-7} G_F$. Clearly these limits are strongly dependent on the assumed upper limit to N_{ν} ; for $N_{\nu} < 3.5$, the limit on G_R is relaxed to $G_R < 0.002$ G_F , since T_f is constrained only to be larger than the temperature corresponding to the QCD transition in the early Universe.

17. THE HUBBLE CONSTANT

Written August 1995 by C.J. Hogan, University of Washington.

In a uniform expanding universe, the position r and velocity v of any particle relative to another obey Hubble's relation $v = H_0 r$, where H_0 is Hubble's constant.* As cosmological distances are measured in Mpc, the natural unit for H_0 is km s⁻¹ Mpc⁻¹, which has the dimensions of inverse time: $[100 \text{ km s}^{-1} \text{ Mpc}^{-1}]^{-1} = 9.78 \times 10^9 \text{ yr.}$

The real universe is nonuniform on small scales, and its motion obeys the Hubble relation only as a large scale average. But as typical non-Hubble motions ("peculiar velocities") are less than about 500 km s⁻¹, on scales more than about 5,000 km s⁻¹ the deviations from Hubble flow are less than about 10%, so the notion of a global Hubble constant is well defined. The value of H_0 averaged over the local 15,000 km s⁻¹ volume is known to lie within 10% of its global value even if H_0 itself is not known this precisely [1–3].

The Hubble constant is only meaningful on very large scales, but very large distances can only be measured indirectly. Distance ratios are measured with selected uniform types of astronomical systems ("Standard Candles") some examples of which are given below. These are used to tie distances to an absolute scale, either the nearby one based on trigonometric parallax or to some system where a physical model is precise enough to yield a distance directly from observed properties. There are many different ways to combine these tools to calibrate large distance, some of which are reviewed here. More complete reviews can be found in Refs. [4–7].

Using stars as standard candles and the Earth's orbit as a baseline, it is possible to tie distances throughout the Galaxy directly to trigonometric parallax measurements. A good landmark point for extragalactic studies is the Large Magellanic Cloud (LMC), a satellite galaxy of our Galaxy whose distance (50 kpc) is known to about 7% and provides confirmation and calibration of other measures. Beyond that, other galaxies in the Local Group (within about 1 Mpc) and other nearby groups provide stepping stones to the Virgo cluster (about 17 Mpc distant), and finally to the Coma cluster (about 100 Mpc distant) and others where the peculiar velocities introduce only small ambiguities. Most of the effort thus lies in obtaining an accurate ratio of distances in the range between Coma (or other similarly distant clusters) and the LMC.

Table 17.1 lists several candles and calibrators with a typical range of distance accessible to each. Usually the ends of the range are not precisely defined; the near end is plagued by small numbers of accessible objects and the far end by signal to noise. The precision quoted is a typical guideline which also varies depending on the sample used; it indicates the error in a distance ratio between an object and some standard reference, not including uncertainties in the absolute calibration of the reference distance (except for the first entry, which lists the typical absolute distance uncertainty in the Cepheid distance to a galaxy.) (The units are astronomical "distance modulus," given by $\mu = 5 \log_{10}(distance in parsecs) - 5.0$; a ± 0.1 magnitude error in magnitude or distance modulus corresponds to a 5% error in distance.) The verification of this precision is made by cross-checking against some other indicator on a galaxy-by-galaxy basis. This provides a control of systematic errors, since we do not expect detailed correlations between (for example) supernova brightness and host-galaxy rotation. Some examples are given in the next column, along with options often used for absolute calibration. The Hubble relation itself is included here, as it is the most precise indication of relative distance for large distances, and is used to verify the standardization of the other candles. As velocities are easy to measure at the relevant precision, a measurement of the Hubble constant is obtained from a calibrated distance measurement at a sufficiently large distance that the Hubble relation itself is precisely defined.

Table 17.1: Selected extragalactic distance indicators.

Technique	Range of distance	Precision	Verification/calibration
Cepheids	<lmc 17="" mpc<="" td="" to=""><td>0.15 mag</td><td>LMC/MWG</td></lmc>	0.15 mag	LMC/MWG
SNIa	4 Mpc to 2 Gpc	$0.1\text{-}0.2~\mathrm{mag}$	Hubble/Model,
			Cepheid
EPM/SNII	LMC to 200 Mpc	0.4 mag	Hubble/Model,
			Cepheid
PNLF	$1~{\rm Mpc~to~20~Mpc}$	0.1 mag	SBF/Cepheid
SBF	$1~{ m Mpc}$ to $60~{ m Mpc}$	0.1 mag	PNLF/Cepheid
TF	$1~{\rm Mpc~to~100~Mpc}$	0.3 mag	Hubble/Cepheid
$D_n - \sigma$	$10~\mathrm{Mpc}$ to $60~\mathrm{Mpc}$	0.4 mag	Hubble/SBF
BCG	50 Mpc to 1 Gpc	$0.2\text{-}0.3~\mathrm{mag}$	Hubble
GCLF	<LMC to 100 Mpc	0.4 mag	SBF/MWG
SZ	$100~\mathrm{Mpc}$ to $> 1~\mathrm{Gpc}$	-	Hubble/Model
GL	\sim 5 Gpc		Model
Hubble	20 Mpc to $\gtrsim 1 \mathrm{Gpc}$	$500 \text{ km s}^{-1} \div H_0 D$	BCG, SNeIa/ H_0

MWG = Milky Way Galaxy †Extracted from [4-7].

17.1. Cepheid variables

The best studied and most trusted of the standard candles, Cepheids are bright stars undergoing overstable oscillations driven by the variation of helium opacity with temperature. The period of oscillation is tightly correlated with the absolute brightness of the star. The calibration of this "period-luminosity relation" ties galaxies to geometrical parallax measurements with about 0.15 mag or 7% precision [8]. There may be some indications of nonuniformity in different populations, but no evidence yet that they are significant. Cepheids have been identified in the Galaxy, the LMC, and in galaxies as distant as M100 in the Virgo cluster, at 17.1 ± 1.8 Mpc [9]. More measurements at large distances are expected from Hubble Space Telescope data. This is an important development because it allows direct absolute calibration of the best distant indicator, SNIa, as well as other methods, to better than 10% accuracy.

17.2. Type Ia supernovae (SNIa)

A SNIa occurs when a degenerate dwarf, of the order of a solar mass and of CNO composition, undergoes explosive detonation or deflagration by nuclear burning to iron-group elements (Ni, Co, Fe). Their uniformity arises because the degenerate material only becomes unstable when it is gravitationally compressed to where the electrons become close to relativistic, which requires nearly a Chandrasekhar mass (1.4 solar masses). Theoretical models of the explosion predict approximately the right peak brightness, but cannot be relied upon for a precise calibration. SNIa are very bright, so their brightness distribution can be studied using the distant Hubble flow as a reference. Indeed, the Hubble diagram of distant SNIa (as well as cases of two SNIa in a single galaxy) shows that they can serve as remarkably precise standard candles; even though they display large variations in brightness, with detailed knowledge of the shape of the light curve, the relative intrinsic brightness of a single SNIa can be predicted to $\Delta m = 0.15$ mag or better and its distance estimated to better than 7% accuracy [10-12]. (Note that distant SNIa can even measure deviation from a linear Hubble law with precision $\Delta q_0 \simeq \Delta m/z$.) Supernovae of all types are fairly rare events, occurring in a typical galaxy every hundred years, so it is only recently that a direct absolute calibration to SNIa host galaxies with Cepheids has been possible.

17.3. Type II supernovae (SNII)

A SNII occurs when a massive star has accumulated 1.4 solar masses of iron group elements in its core; there is then no source of nuclear energy and the core collapses by the Chandrasekhar instability. The collapse to a neutron star releases a large gravitational binding energy, some of which powers an explosion. The large variety of envelopes around collapsing cores means that SNII are not at all uniform in their properties. However, their distances can be calibrated absolutely by the fairly reliable "expanding photosphere method" (EPM). The principle is most easily understood for an expanding spherical blackbody. Even if the disk is unresolved, the continuum spectrum yields the angular size from spectral temperature and absolute flux. Spectral lines yield the expansion velocity, which from knowledge of the elapsed time gives a physical size and hence a distance. Models of real photospheres are not so simple but yield individual distances accurate to about 20% [13]. This is in principle an independent absolute distance, but is precisely verified by comparison with Cepheids in several cases, the distant Hubble diagram and Tully Fisher distance ratios (described below) in several others, and by multiple-epoch fits of the same object.

17.4. Planetary nebula luminosity function (PNLF)

A planetary nebula (PN) forms when the gaseous envelope is ejected from a low-mass star as its core collapses to a white dwarf. We see bright fluorescent radiation from the ejected gas shell, excited by UV light from the hot new white dwarf. The line radiation makes PN's easy to find and measure even in far-away galaxies; a bright galaxy can have tens of thousands, of which hundreds are bright enough to use to construct a PNLF. It is found empirically that the range of PN brightnesses has a sharp upper cutoff that appears to provide a good empirical standard candle, verified by comparison with SBF distance ratios.

17.5. Surface brightness fluctuations (SBF)

When galaxies are farther away than the Local Group, atmospheric blurring causes stellar images to blend together. However, with modern linear detectors, it is still possible to measure the moments of the distribution of stellar brightness in a population (in particular, the brightness-weighted average stellar brightness) through spatial fluctuations in the light. Stellar populations in elliptical galaxies appear to be universal enough for this to be a remarkably good standard candle, as verified by comparison with PNLF distance ratios. Note the problem of absolute calibration: as there are no elliptical galaxies with Cepheids, instead one uses the bulge components of nearby spirals, which have similar populations.

17.6. Tully-Fisher (TF)

The TF relation refers to a correlation of the properties of whole spiral galaxies, between rotational velocity and total luminosity. In rough terms, the relation can be understood as a relation between mass and luminosity, but given the variation in structural properties and stellar populations the narrow relation is a surprisingly good standard candle. Looking at a whole galaxy gives a long range and wide applicability. The TF distance ratios and precision have been verified by cross-checking against all of the above candles, and against the Hubble flow, particularly galaxy cluster averages, which permit greater precision. The absolute calibration of TF is traditionally made by a handful of local galaxies, with Cepheid calibration, and a major thrust now is to extend Cepheid measurements to a larger, more representative, and more distant sample, especially to galaxies in the Virgo cluster.

17.7. $D_n-\sigma$

A rough equivalent to TF for elliptical galaxies, D_n – σ is a correlation between galaxy size and velocity dispersion. It has a larger dispersion than TF and less opportunity for local calibration, but it is particularly useful for verifying distance ratios of galaxy clusters, whose cores contain almost no spirals.

17.8. Brightest cluster galaxies (BCG)

As a result of agglomeration, rich clusters of galaxies have accumulated the largest and brightest galaxies in the universe in their centers. They are very nearly all the same brightness; when account is taken of their light profiles, they are even more uniform. These provide the best check on the approach to uniform Hubble flow on large scales. (Quasars, which are even brighter, are far too variable to be good standard candles).

17.9. Globular cluster luminosity function (GCLF)

Many galaxies have systems of globular clusters orbiting them, each of which contain hundreds of thousands of stars and hence is visible at large distances. It is assumed that similar galaxies ought to have similar distributions of globular cluster luminosity, and current work is centered on verifying the precision of this assumption.

17.10. Sunyaev-Zeldovich effect (SZ)

The electron density and temperature of the hot plasma in a cluster of galaxies can be measured in two ways which depend differently on distance: the thermal x-ray emission, which is mostly bremsstrahlung by hot electrons, and the Sunyaev-Zeldovich effect on the microwave background, caused by Compton scattering off the electrons. This provides in principle an absolute calibration. Although the model has other unconstrained parameters, such as the gas geometry, which limit the precision and reliability of distances, in the handful of cases which have been studied most recently the distances are broadly in accord with those obtained by the other techniques.

17.11. Gravitational lenses (GL)

The time delay δt between different images of a high redshift gravitationally lensed quasar is $\delta t = C(z_Q, z_l)\delta\theta^2/H_0 \approx 1$ yr for image separations $\delta\theta$ of the order of arcseconds, with a numerical factor C of order unity determined by the specific lens geometry (the angular distribution of the lensing matter) and background cosmology. Variability of the double quasar 0957+561 has permitted measurements of δt from time series correlation, but these remain controversial and ambiguous, yielding correlation peaks at both 415 and 540 days. Although lensing does not yet provide a precise measurement, it is an amazing sanity check that this system, which relies on no other intermediate steps for its calibration, gives estimates on the scale of the Hubble length which are broadly consistent with local measures of H_0 .

17.12. Estimates of H_0

The central idea is to find "landmark" systems whose distance is given by more than one technique. Systems are not always well defined, however. For example, the LMC size is a few percent of its distance, introducing errors of this order for any calibration based on an individual object within it. Nor are galaxy clusters as compact and well defined as individual galaxies; using galaxy clusters as calibrating systems often requires some assumptions and models about cluster membership (the most important example being the Virgo cluster, whose structure is somewhat amorphous, creating a $\pm 20\%$ or more distance ambiguity in some arguments). The best way to avoid this is to cross-correlate calibrators on a galaxy-by-galaxy basis, but this introduces problems of bias associated with sample selection that must be modeled. The basic difficulty remains that the nearby calibrators of any sort remain few and possibly anomalous.

The reason for the variable estimates of the Hubble constant lies in the many different ways to combine these techniques to obtain an absolute distance calibration in the Hubble flow, each involving several, usually individually reasonable, assumptions. Nevertheless there is broad agreement within the errors among a wide variety of independent ladders with different systematics. As examples, we cite a variety of (somewhat arbitrarily chosen) independent methods, which illustrate some of the choices and tradeoffs, summarized in Table 17.2.

- 1. Expanding photosphere method (EPM) distances give an absolute calibration to objects in the distant Hubble flow. A small sample of these direct distances with small flow corrections gives $H_0=73\pm6$ (statistical) ±7 (systematic).The distance estimates and limits on the systematic error component are verified by Cepheid distances in three cases, where the Cepheid/EPM distances come out to 1.02 ± 0.08 (LMC), $1.01^{+0.23}_{-0.17}$ (M101) and 1.13 ± 0.28 (M100).
- 2. With HST, it is now possible to calibrate SNIa directly with Cepheid distances to host galaxies. The light from brighter SNIa decays more slowly than from faint ones, so the best fits to the distant Hubble diagram include information about the light curve shape ("LCS") rather than simply assuming uniformity; low values of H_0 arise in the latter case. There are several options for empirical calibration, among them: (a) Three individual SNIa host galaxy distances have been calibrated directly with Cepheids. There is evidence from their light curves that two of these calibrators may indeed be unusually bright, which explains why the value of H_0 depends on whether or not the LCS correction is applied (a fourth, SN 1990N in N4639 is appearing as this goes to press, with more on the way). (b) Alternatively, assuming that the mean of six well-studied SNIa in the Virgo cluster lies at the Cepheid Virgo distance of 17 Mpc yields $H_0 = 71 \pm 7 \text{ km s}^{-1}$ Mpc^{-1} .
- 3. The distance to Virgo or any other local cluster is tied to H_0 via the distant Hubble diagram for TF or D_n - σ distances for galaxies in distant clusters. This can be done with a large scale flow model fit to many clusters. Using a Virgo distance of 17 Mpc yields $H_0 = 82 \pm 11 \text{ km s}^{-1} \text{ Mpc}^{-1}$. Alternatively, we can use the distance ratio to a fiducial reference such as the Coma cluster, for which such models predict almost vanishing peculiar velocity, and which is in any case distant enough for flow to be unimportant. (The flow models give its Hubble velocity as $7170 \pm 125 \text{ km s}^{-1}$; relative to the CMBR its velocity is $7197 \pm 73 \text{ km s}^{-1}$.) If (as estimated from TF, D_n - σ , SNeI) the Coma to Virgo ratio lies in the range 5.5 to 5.75, 17 Mpc for Virgo leads to $H_0 = 77$ to 73 km s⁻¹ Mpc⁻¹, subject to uncertainty over the Virgo depth. Nearly the same TF calibration is given by six local Cepheid calibrators, and by several more in the M101 group. This avoids the Virgo depth uncertainty, but replaces it with doubts about whether all of the local calibrators might be anomalous (although the apparent uniformity of galaxies elsewhere argues against this being a large effect.)
- 4. TF comparison with distant field galaxies in the Hubble flow (after corrections for Malmquist bias in the samples, which is worse than in cluster samples) yield $H_0=80\pm10~{\rm km~s^{-1}~Mpc^{-1}}$.
- 5. For completeness, some recent SZ and GL estimates are shown. The GL estimate in the best model [25] depends on the convergence κ added to the main galaxy lens by the cluster potential; κ probably lies between 0.1 and 0.2, and must be greater than zero, providing a firm upper limit on H_0 and an estimate squarely in the range of the other techniques.

The central values by most reliably calibrated methods lie in the range $H_0=65$ to 85 km s⁻¹ Mpc⁻¹, and indeed this corresponds roughly with the range of estimates expected from the internally estimated errors. Thus systematic errors are at least not dominant, although they could well be comparable to internal errors. The simplicity and apparent precision of the new Cepheid + SNIa ladder lead one to suspect a true value in the lower end of this range.

[‡] TF calibration from 6 local Cepheid calibration is verified by M101 group galaxies and (less directly) by M100 and NGC 4571 distance to Virgo TF galaxies [9,14,26].

18. DARK MATTER

Written September 1995 by M. Srednicki, University of California, Santa Barbara

There is strong evidence from a variety of different observations for a large amount of dark matter in the universe [1]. The phrase "dark matter" means matter whose existence has been inferred only through its gravitational effects. There is also extensive circumstantial evidence that at least some of this dark matter is nonbaryonic: that is, composed of elementary particles other than protons, neutrons, and electrons. These particles must have survived from the Big Bang, and therefore must either be stable or have lifetimes in excess of the current age of the universe.

The abundance of dark matter is usually quoted in terms of its mass density $\rho_{\rm dm}$ in units of the critical density, $\Omega_{\rm dm}=\rho_{\rm dm}/\rho_{\rm c}$; the critical density $\rho_{\rm c}$ is defined in Eq. (15.5) (in Section 15 on "Big-Bang Cosmology" in this Review). The total amount of visible matter (that is, matter whose existence is inferred from its emission or absorption of photons) is roughly $\Omega_{\rm vis}\simeq 0.005,$ with an uncertainty of at least a factor of two.

The strongest evidence for dark matter is from the rotation curves of spiral galaxies [1,2]. In these observations, the circular velocity v_c of hydrogen clouds surrounding the galaxy is measured (via Doppler shift) as a function of radius r. If there were no dark matter, at large rwe would find $v_c^2 \simeq G_N M_{\rm vis}/r$, since the visible mass $M_{\rm vis}$ of a spiral galaxy is concentrated at its center. However, observations of many spiral galaxies instead indicate a velocity v_c which is independent of r at large r, with a typical value $v_c \sim 200 \, \mathrm{km \ s^{-1}}$. Such a "flat rotation curve" implies that the total mass within radius r grows linearly with $r, M_{\rm tot}(r) \simeq G_N^{-1} v_{\rm c}^2 r$. A self-gravitating ball of ideal gas at a uniform temperature of $kT=\frac{1}{2}m_{\rm dm}v_{\rm c}^2$ would have this mass profile; here $m_{\rm dm}$ is the mass of one dark matter particle. The rotation curves are measured out to some tens of kiloparsecs, implying a total mass within this radius which is typically about ten times the visible mass. This would imply $\Omega_{\rm dm} \gtrsim 10\,\Omega_{\rm vis} \simeq 0.05.$ In our own galaxy, estimates of the local density of dark matter typically give $\rho_{\rm dm} \simeq 0.3\,{\rm GeV~cm^{-3}},$ but this result depends sensitively on how the halo of dark matter is modeled.

Other indications of the presence of dark matter come from observations of the motion of galaxies and hot gas in clusters of galaxies [3]. The overall result is that $\Omega_{\rm dm}\sim 0.2$. Studies of large-scale velocity fields result in $\Omega_{\rm dm}\gtrsim 0.3$ [4]. However, these methods of determining $\Omega_{\rm dm}$ require some astrophysical assumptions about how galaxies form.

None of these observations give us any direct indication of the nature of the dark matter. If it is baryonic, the forms it can take are severely restricted, since most forms of ordinary matter readily emit and absorb photons in at least one observable frequency band [5]. Possible exceptions include remnants (white dwarfs, neutron stars, black holes) of an early generation of massive stars, or smaller objects which never initiated nuclear burning (and would therefore have masses less than about $0.1\,M_\odot$). These massive compact halo objects are collectively called machos. Preliminary results [6] of a search for machos via gravitational lensing effects indicate that a standard halo has a mass fraction of no more than 0.66 of machos with mass less than $0.1\,M_\odot$ at the 95% confidence level, but it is possible to construct models of an all-macho halo which are consistent with all observations.

There are, however, several indirect arguments which argue for a substantial amount of nonbaryonic dark matter. First, nucleosynthesis gives the limits $0.010 \le \Omega_{\rm b}h_0^2 \le 0.016$ for the total mass of baryons; h_0 is defined in Eq. (15.6) (in Section 15 on "Big-Bang Cosmology" in this Review). The upper limit on $\Omega_{\rm b}$ is substantially below the value $\Omega_{\rm dm} \gtrsim 0.3$ given by large scale measurements, even if h_0 is near the lower end of its optimistically allowed range, $0.4 \le h_0 \le 1.0$. A second, purely theoretical argument is that inflationary models (widely regarded as providing explanations of a number of otherwise puzzling paradoxes) generically predict $\Omega_{\rm total} = 1$. Finally, without nonbaryonic dark matter it is difficult to construct a model of galaxy formation that predicts sufficiently small fluctuations in the cosmic microwave background radiation [7].

For purposes of galaxy formation models, nonbaryonic dark matter is classified as "hot" or "cold," depending on whether the dark matter particles were relativistic or nonrelativistic at the time when the horizon of the universe enclosed enough matter to form a galaxy. If the dark matter particles are in thermal equilibrium with the baryons and radiation, then only the mass of a dark matter particle is relevant to knowing whether the dark matter is hot or cold, with the dividing line being $m_{\rm dm} \sim 1\,{\rm keV}$. In addition, specifying a model requires giving the power spectrum of initial density fluctuations. Inflationary models generically predict a power spectrum which is nearly scale invariant. Given this, models with only cold dark matter are much more successful than models with only hot dark matter at reproducing the observed structure of our universe. Some lingering discrepancies in the cold dark matter model are removed in models with both kinds of dark matter [8]. Another class of models uses mass fluctuations due to topological defects, but these are much harder to analyze with comparable quantitative detail [9].

The best candidate for hot dark matter is one of the three neutrinos, endowed with a Majorana mass m_{ν} . Such a neutrino would contribute $\Omega_{\nu} = 0.56\,G_N\,T_0^3\,H_0^{-2}m_{\nu} = m_{\nu}/(92\,h_0^2\,\mathrm{eV})$, where T_0 is the present temperature of the cosmic microwave background radiation. There is another constraint on neutrinos (or any light fermions) if they are to comprise the halos of dwarf galaxies: the Pauli exclusion principle restricts the number that can fit into the phase space of a halo [10], which puts a lower limit on the neutrino mass of $m_{\nu} \gtrsim 80\,\mathrm{eV}$.

There are no presently known particles which could be cold dark matter. However, many proposed extensions of the Standard Model predict a stable (or sufficiently long lived) particle. The key question then becomes the predicted value of $\Omega_{\rm dm}$.

If the particle is its own antiparticle (or there are particles and antiparticles present in equal numbers), and these particles were in thermal equilibrium with radiation at least until they became nonrelativistic, then their relic abundance is determined by their annihilation cross section $\sigma_{\rm ann}\colon\Omega_{\rm dm}\sim G_N^{3/2}T_0^3H_0^{-2}\langle\sigma_{\rm ann}v_{\rm rel}\rangle^{-1}.$ Here $v_{\rm rel}$ is the relative velocity of the two incoming dark matter particles, and the angle brackets denote an averaging over a thermal distribution of velocities for each at the freezeout temperature $T_{\rm fr}$ when the dark matter particles go out of thermal equilibrium with radiation; typically $T_{\rm fr}\simeq\frac{1}{20}m_{\rm dm}.$ One then finds (putting in appropriate numerical factors) that $\Omega_{\rm dm}h_0^2\simeq 3\times 10^{-27}\,{\rm cm}^3\,{\rm s}^{-1}/\langle\sigma_{\rm ann}v_{\rm rel}\rangle}$. The value of $\langle\sigma_{\rm ann}v_{\rm rel}\rangle$ needed for $\Omega_{\rm dm}\simeq 1$ is remarkably close to what one would expect for a weakly interacting massive particle (wimp) with a mass of $m_{\rm dm}=100\,{\rm GeV}$: $\langle\sigma_{\rm ann}v_{\rm rel}\rangle\sim\alpha^2/8\pi m_{\rm dm}^2\sim 3\times 10^{-27}\,{\rm cm}^3\,{\rm s}^{-1}.$

If the dark matter particle is not its own antiparticle, and the number of particles minus antiparticles is conserved, then an initial asymmetry in the abundances of particles and antiparticles will be preserved, and can give relic abundances much larger than those predicted above.

If the dark matter particles were never in thermal equilibrium with radiation, then their abundance today must be calculated in some other way, and will in general depend on the precise initial conditions which are assumed.

The two best known and most studied cold dark matter candidates are the neutralino and the axion. The neutralino is predicted by supersymmetric extensions of the Standard Model [11,12]. It qualifies as a wimp, with a theoretically expected mass in the range of tens to hundreds of GeV. The axion is predicted by extensions of the Standard Model which resolve the strong CP problem [13]. Its mass must be approximately $10^{-5}\,\mathrm{eV}$ if it is to be a significant component of the dark matter. Axions can occur in the early universe in the form of a Bose condensate which never comes into thermal equilibrium; these axions are always nonrelativistic, despite their small mass.

There are prospects for direct experimental detection of both these candidates (and other wimp candidates as well). Wimps will scatter off nuclei at a calculable rate, and produce observable nuclear recoils [12,14]. This technique has been used to show that all the dark matter cannot consist of massive Dirac neutrinos or scalar neutrinos (predicted by supersymmetric models) with masses in the

range of $10\,\mathrm{GeV} \lesssim m_\mathrm{dm} \lesssim 4\,\mathrm{TeV}$ [15]. The neutralino is harder to detect because its scattering cross section with nuclei is considerably smaller. The axion can be detected by axion to photon conversion in an inhomogeneous magnetic field, and limits on the allowed axion-photon coupling have been set (which, however, do not exclude the theoretically favored value) [13]. Both types of detection experiments are in progress.

Wimp candidates can have indirect signatures as well, via present-day annihilations into particles which can be detected as cosmic rays [12]. The most promising possibility arises from the fact that wimps collect at the centers of the sun and the earth, thus greatly increasing their annihilation rate, and producing high energy neutrinos which can escape and arrive at the earth's surface in potentially observable numbers.

19. COSMIC BACKGROUND RADIATION

Revised February 1996 by G.F. Smoot and D. Scott

19.1. Introduction

The observed cosmic microwave background (CMB) radiation provides strong evidence for the hot big bang. The success of primordial nucleosynthesis calculations (see Sec. 16, "Big-bang nucleosynthesis") requires a cosmic background radiation (CBR) characterized by a temperature $kT\sim 1\,\mathrm{MeV}$ at a redshift of $z\simeq 10^9$. In their pioneering work, Gamow, Alpher, and Herman [1] realized this and predicted the existence of a faint residual relic, primordial radiation, with a present temperature of a few degrees. The observed CMB is interpreted as the current manifestation of the hypothesized CBR.

The CMB was serendipitously discovered by Penzias and Wilson [2] in 1965. Its spectrum is well characterized by a $2.73 \pm 0.01 \, \mathrm{K}$ black-body (Planckian) spectrum over more than three decades in frequency (see Fig. 19.1). A non-interacting Planckian distribution of temperature T_i at redshift z_i transforms with the universal expansion to another Planckian distribution at redshift z_r with temperature $T_r/(1+z_r) = T_i/(1+z_i)$. Hence thermal equilibrium, once established (e.g. at the nucleosynthesis epoch), is preserved by the expansion, in spite of the fact that photons decoupled from matter at early times. Because there are about 10^9 photons per nucleon, the transition from the ionized primordial plasma to neutral atoms at $z \sim 1000$ does not significantly alter the CBR spectrum [3].

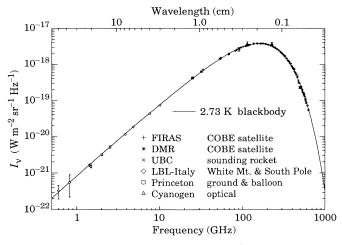

Figure 19.1: Precise measurements of the CMB spectrum. The line represents a 2.73 K blackbody, which describes the spectrum very well, especially around the peak of intensity. The spectrum is less well constrained at 10 cm and longer wavelengths. (References for this figure are at the end of this section under "CMB Spectrum References.")

19.2. Theoretical spectral distortions

The remarkable precision with which the CMB spectrum is fitted by a Planckian distribution provides limits on possible energy releases in the early Universe, at roughly the fractional level of 10^{-4} of the CBR energy, for redshifts $\lesssim 10^7$ (corresponding to epochs $\gtrsim 1\,\mathrm{year}$). The following three important classes of spectral distortions (see Fig. 19.2) generally correspond to energy releases at different epochs. The distortion results from the CBR photon interactions with a hot electron gas at temperature T_e .

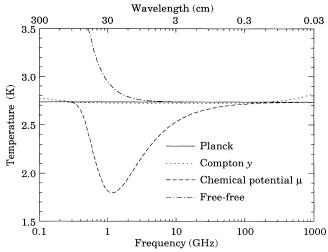

Figure 19.2: The shapes of expected, but so far unobserved, CMB distortions, resulting from energy-releasing processes at different epochs.

19.2.1. Compton distortion: Late energy release $(z \lesssim 10^5)$. Compton scattering $(\gamma e \to \gamma' e')$ of the CBR photons by a hot electron gas creates spectral distortions by transfering energy from the electrons to the photons. Compton scattering cannot achieve thermal equilibrium for y < 1, where

$$y = \int_0^z \frac{kT_e(z') - kT_{\gamma}(z')}{m_e c^2} \, \sigma_T \, n_e(z') \, c \, \frac{dt}{dz'} \, dz' \,, \tag{19.1}$$

is the integral of the number of interactions, $\sigma_T n_e(z) c dt$, times the mean-fractional photon-energy change per collision [4]. For $T_e \gg T_{\gamma}$ y is also proportional to the integral of the electron pressure $n_e k T_e$ along the line of sight. For standard thermal histories y < 1 for epochs later than $z \simeq 10^5$.

The resulting CMB distortion is a temperature decrement

$$\Delta T_{\rm RJ} = -2y T_{\gamma} \tag{19.2}$$

in the Rayleigh-Jeans $(h\nu/kT\ll 1)$ portion of the spectrum, and a rapid rise in temperature in the Wien $(h\nu/kT\gg 1)$ region, i.e. photons are shifted from low to high frequencies. The magnitude of the distortion is related to the total energy transfer [4] ΔE by

$$\Delta E/E_{\rm CBR} = e^{4y} - 1 \simeq 4y \ .$$
 (19.3)

A prime candidate for producing a Comptonized spectrum is a hot intergalactic medium. A hot $(T_e>10^5~{\rm K})$ medium in clusters of galaxies can and does produce a partially Comptonized spectrum as seen through the cluster, known as the Sunyaev-Zel'dovich effect. Based upon X-ray data, the predicted large angular scale total combined effect of the hot intracluster medium should produce $y\lesssim 10^{-6}$ [5].

19.2.2. Bose-Einstein or chemical potential distortion: Early energy release ($z \sim 10^5$ – 10^7). After many Compton scatterings (y > 1), the photons and electrons will reach statistical (not thermodynamic) equilibrium, because Compton scattering conserves photon number. This equilibrium is described by the Bose-Einstein distribution with non-zero chemical potential:

$$n = \frac{1}{e^{x + \mu_0} - 1} \,, \tag{19.4}$$

where $x \equiv h\nu/kT$ and $\mu_0 \simeq 1.4~\Delta E/E_{\rm CBR}$, with μ_0 being the dimensionless chemical potential that is required.

The collisions of electrons with nuclei in the plasma produce free-free (thermal bremsstrahlung) radiation: $eZ \rightarrow eZ\gamma$. Free-free

emission thermalizes the spectrum to the plasma temperature at long wavelengths. Including this effect, the chemical potential becomes frequency-dependent,

$$\mu(x) = \mu_0 e^{-2x_b/x} , \qquad (19.5)$$

where x_b is the transition frequency at which Compton scattering of photons to higher frequencies is balanced by free-free creation of new photons. The resulting spectrum has a sharp drop in brightness temperature at centimeter wavelengths [6]. The minimum wavelength is determined by Ω_B .

The equilibrium Bose-Einstein distribution results from the oldest non-equilibrium processes ($10^5 < z < 10^7$), such as the decay of relic particles or primordial inhomogeneities. Note that free-free emission (thermal bremsstrahlung) and radiative-Compton scattering effectively erase any distortions [7] to a Planckian spectrum for epochs earlier than $z \sim 10^7$.

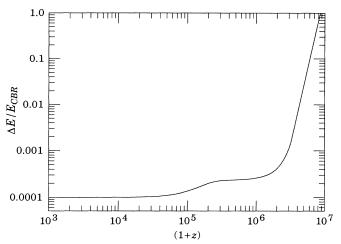

Figure 19.3: Upper Limits (95% CL) on fractional energy $(\Delta E/E_{\rm CBR})$ releases as set by lack of CMB spectral distortions resulting from processes at different epochs. These can be translated into constraints on the mass, lifetime and photon branching ratio of unstable relic particles, with some additional dependence on cosmological parameters such as Ω_B [9,10].

19.2.3. Free-free distortion: Very late energy release ($z \ll 10^3$). Free-free emission can create rather than erase spectral distortion in the late universe, for recent reionization ($z < 10^3$) and from a warm intergalactic medium. The distortion arises because of the lack of Comptonization at recent epochs. The effect on the present-day CMB spectrum is described by

$$\Delta T_{ff} = T_{\gamma} Y_{ff} / x^2, \tag{19.6}$$

where T_{γ} is the undistorted photon temperature, x is the dimensionless frequency, and Y_{ff}/x^2 is the optical depth to free-free emission:

$$Y_{ff} = \int_0^z \frac{T_e(z') - T_\gamma(z')}{T_e(z')} \frac{8\pi e^6 h^2 n_e^2 g}{3m_e(kT_\gamma)^3 \sqrt{6\pi m_e kT_e}} \frac{dt}{dz'} dz' . \quad (19.7)$$

Here h is Planck's constant, n_e is the electron density and g is the Gaunt factor [8].

19.2.4. Spectrum summary: The CMB spectrum is consistent with a blackbody spectrum over more than three decades of frequency around the peak. A least-squares fit to all CMB measurements yields:

$$\begin{split} T_{\gamma} &= 2.73 \pm 0.01 \text{ K} \\ n_{\gamma} &= (2\zeta(3)/\pi^2) T_{\gamma}^3 \simeq 413 \text{ cm}^{-3} \\ \rho_{\gamma} &= (\pi^2/15) T_{\gamma}^4 \simeq 4.68 \times 10^{-34} \, \text{g cm}^{-3} \simeq 0.262 \, \text{eV cm}^{-3} \\ |y| &< 1.5 \times 10^{-5} \qquad (95\% \text{ CL}) \\ |\mu_0| &< 9 \times 10^{-5} \qquad (95\% \text{ CL}) \\ |Y_{ff}| &< 1.9 \times 10^{-5} \qquad (95\% \text{ CL}) \end{split}$$

The limits here [11] correspond to limits [11–13] on energetic processes $\Delta E/E_{\rm CBR} < 2 \times 10^{-4}$ occurring between redshifts 10^3 and 5×10^6 (see Fig. 19.3). The best-fit temperature from the COBE FIRAS experiment is $T_{\gamma} = 2.728 \pm 0.002 \, {\rm K}$ [11].

19.3. Deviations from isotropy

Penzias and Wilson reported that the CMB was isotropic and unpolarized to the 10% level. Current observations show that the CMB is unpolarized at the 10^{-5} level but has a dipole anisotropy at the 10^{-3} level, with smaller-scale anisotropies at the 10^{-5} level. Standard theories predict anisotropies in linear polarization well below currently achievable levels, but temperature anisotropies of roughly the amplitude now being detected.

It is customary to express the CMB temperature on the sky in a spherical harmonic expansion,

$$T(\theta,\phi) = \sum_{\ell m} a_{\ell m} Y_{\ell m}(\theta,\phi) , \qquad (19.8)$$

and to discuss the various multipole amplitudes. The power at a given angular scale is roughly $\ell \sum_m \left|a_{\ell m}\right|^2/4\pi$, with $\ell \sim 1/\theta$.

19.3.1. The dipole: The largest anisotropy is in the $\ell=1$ (dipole) first spherical harmonic, with amplitude at the level of $\Delta T/T=1.23\times 10^{-3}$. The dipole is interpreted as the result of the Doppler shift caused by the solar system motion relative to the nearly isotropic blackbody field. The motion of the observer (receiver) with velocity $\beta=v/c$ relative to an isotropic Planckian radiation field of temperature T_0 produces a Doppler-shifted temperature

$$T(\theta) = T_0 (1 - \beta^2)^{1/2} / (1 - \beta \cos \theta)$$

= $T_0 \left(1 + \beta \cos \theta + (\beta^2/2) \cos 2\theta + O(\beta^3) \right)$. (19.9)

The implied velocity [11,14] for the solar-system barycenter is $\beta=0.001236\pm0.000002$ (68% CL) or $v=371\pm0.5\,\mathrm{km\,s^{-1}}$, assuming a value $T_0=2.728\pm0.002\,\mathrm{K}$, towards $(\alpha,\delta)=(11.20^{\mathrm{h}}\pm0.01^{\mathrm{h}},-7.0^{\mathrm{o}}\pm0.2^{\mathrm{o}}),$ or $(\ell,b)=(264.14^{\mathrm{o}}\pm0.15^{\mathrm{o}},48.26^{\mathrm{o}}\pm0.15^{\mathrm{o}}).$ Such a solar-system velocity implies a velocity for the Galaxy and the Local Group of galaxies relative to the CMB. The derived velocity is $v_{\mathrm{LG}}=627\pm22\,\mathrm{km\,s^{-1}}$ toward $(\ell,b)=(276^{\mathrm{o}}\pm3^{\mathrm{o}},30^{\mathrm{o}}\pm3^{\mathrm{o}}),$ where most of the error comes from uncertainty in the velocity of the solar system relative to the Local Group.

The Doppler effect of this velocity and of the velocity of the Earth around the Sun, as well as any velocity of the receiver relative to the Earth, is normally removed for the purposes of CMB anisotropy study. The resulting high degree of CMB isotropy is the strongest evidence for the validity of the Robertson-Walker metric.

19.3.2. The quadrupole: The rms quadrupole anisotropy amplitude is defined through $Q_{\rm rms}^2/T_\gamma^2=\sum_m |a_{2m}|^2/4\pi$. The current estimate of its value is $4\,\mu{\rm K}\leq Q_{\rm rms}\leq 28\,\mu{\rm K}$ for a 95% confidence interval [15]. The uncertainty here includes both statistical errors and systematic errors, which are dominated by the effects of galactic emission modelling. This level of quadrupole anisotropy allows one to set precise limits on anisotropic expansion, shear, and vorticity; all such dimensionless quantities are constrained to be less than about 10^{-5} .

19.3.3. Smaller angular scales: The COBE-discovered [16] higher-order $(\ell > 2)$ anisotropy is interpreted as being the result of perturbations in the energy density of the early Universe, manifesting themselves at the epoch of the CMB's last scattering. Hence the detection of these anisotropies has provided evidence for the existence of the density perturbations that seeded all the structure we observe today.

In the standard scenario the last scattering takes place at a redshift of approximately 1100, at which epoch the large number of photons was no longer able to keep the hydrogen sufficiently ionized. The optical thickness of the cosmic photosphere is roughly $\Delta z \sim 100$ or about 5 arcminutes, so that features smaller than this size are damped.

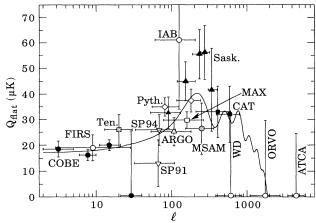

Figure 19.4: Current status of CMB anisotropy observations, adapted from Scott, Silk, & White (1995) [17]. This is a representation of the results from COBE, together with a wide range of ground- and balloon-based experiments which have operated in the last few years. Plotted are the quadrupole amplitudes for a flat (unprocessed scale-invariant spectrum of primordial perturbations, i.e., a horizontal line) anisotropy spectrum that would give the observed results for each experiment. In other words each point is the normalization of a flat spectrum derived from the individual experiments. The vertical error bars represent estimates of 68% CL, while the upper limits are at 95% CL. Horizontal bars indicate the range of ℓ values sampled. The curve indicates the expected spectrum for a standard CDM model ($\Omega_0 = 1, \Omega_B = 0.05, h = 0.5$), although true comparison with models should involve convolution of this curve with each experimental filter function. (References for this figure are at the end of this section under "CMB Anisotropy References.")

Anisotropies are observed on angular scales larger than this damping scale (see Fig. 19.4), and are consistent with those expected from an initially scale-invariant power spectrum (flat = independent of scale) of potential and thus metric fluctuations. It is believed that the large scale structure in the Universe developed through the process of gravitational instability, where small primordial perturbations in energy density were amplified by gravity over the course of time. The initial spectrum of density perturbations can evolve significantly in the epoch z>1100 for causally connected regions (angles $\lesssim 1^{\rm o} \, \Omega_{\rm tot}^{1/2}$). The primary mode of evolution is through adiabatic (acoustic) oscillations, leading to a series of peaks that encode information about the perturbations and geometry of the universe, as well as information on $\Omega_0, \, \Omega_B, \, \Omega_\Lambda$ (cosmological constant), and H_0 [17]. The location of the first acoustic peak is predicted to be at $\ell \sim 220 \, \Omega_{\rm tot}^{-1/2}$ or $\theta \sim 0.3^{\rm o} \, \Omega_{\rm tot}^{1/2}$ and its amplitude increases with increasing Ω_B .

Theoretical models often predict a power spectrum in spherical harmonic amplitudes, since the models lead to primordial fluctuations and thus $a_{\ell m}$ that are Gaussian random fields, and hence the power spectrum in ℓ is sufficient to characterize the results. The power at each ℓ is $(2\ell+1)C_\ell/(4\pi)$, where $C_\ell \equiv \langle |a_{\ell m}|^2 \rangle$. For an idealized full-sky observation, the variance of each measured C_ℓ is $[2/(2\ell+1)]C_\ell^2$. This sampling variance (known as cosmic variance) comes about because each C_ℓ is chi-squared distributed with $(2\ell+1)$ degrees of freedom for our observable volume of the Universe [18].

Figure 19.5 shows the theoretically predicted anisotropy power spectrum for a sample of models, plotted as $\ell(\ell+1)C_\ell$ versus ℓ which is the power per logarithmic interval in ℓ or, equivalently, the two-dimensional power spectrum. If the initial power spectrum of perturbations is the result of quantum mechanical fluctuations produced and amplified during inflation, then the shape of the anisotropy spectrum is coupled to the ratio of contributions from density (scalar) and gravity wave (tensor) perturbations. If the energy scale of inflation at the appropriate epoch is at the level of

 $\simeq 10^{16} {\rm GeV},$ then detection of the effect of gravitons is possible, as well as partial reconstruction of the inflaton potential. If the energy scale is $\lesssim 10^{14} {\rm GeV},$ then density fluctuations dominate and less constraint is possible.

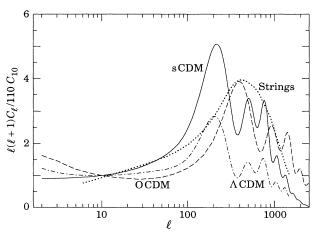

Figure 19.5: Examples of theoretically predicted $\ell(\ell+1)C_\ell$ or CMB anisotropy power spectra. sCDM is the standard cold dark matter model with h=0.5 and $\Omega_B=0.05$. Λ CDM is a model with $\Omega_{\rm tot}=\Omega_{\Lambda}+\Omega_0=1$, with $\Omega_{\Lambda}=0.3$ and h=0.8. OCDM is an open model with $\Omega_0=0.3$ and h=0.75 (see [19] for models). Strings is a model where cosmic strings are the primary source of large scale structure [20]. The plot indicates that precise measurements of the CMB anisotropy power spectrum could distinguish between current models.

Fits to data over smaller angular scales are often quoted as the expected value of the quadrupole $\langle Q \rangle$ for some specific theory, e.g. a model with power-law initial conditions (primordial density perturbation power spectrum $P(k) \propto k^n$). The full 4-year COBE DMR data give $\langle Q \rangle = 15.3^{+3.7}_{-2.8}~\mu \text{K}$, after projecting out the slope dependence, while the best-fit slope is $n=1.2\pm0.3$, and for a pure n=1 (scale-invariant potential perturbation) spectrum $\langle Q \rangle (n=1) = 18\pm1.6~\mu \text{K}$ [15,21]. The conventional notation is such that $\langle Q \rangle^2/T_\gamma^2 = 5C_2/4\pi$. The fluctuations measured by other experiments can also be quoted in terms of Q_{flat} , the equivalent value of the quadrupole for a flat (n=1) spectrum, as presented in Fig. 19.4.

It now seems clear that there is more power at sub-degree scales than at COBE scales, which provides some model-dependent information on cosmological parameters [17,22], for example Ω_B . In terms of such parameters, fits to the COBE data alone yield $\Omega_0 > 0.34$ at 95% CL [23] and $\Omega_{\rm tot} < 1.5$ also at 95% CL [24], for inflationary models. Only somewhat weak conclusions can be drawn based on the current smaller angular scale data (see Fig. 19.4). A sample preliminary fit [25] finds $\Omega_{\rm tot} = 0.7^{+1.0}_{-0.4}$ and $30 < H_0 < 70~{\rm km\,s^{-1}Mpc^{-1}}$ for a limited range of cosmological models.

However, new data are being acquired at an increasing rate, with a large number of improved ground- and balloon-based experiments being developed. It appears that we are not far from being able to distinguish crudely between currently favored models, and to begin a more precise determination of cosmological parameters. A vigorous suborbital and interferometric program could map out the CMB anisotropy power spectrum to about 10% accuracy and determine several parameters at the 10 to 20% level in the next few years. Ultimately, on the scale of a perhaps 5–10 years, there is the prospect of another satellite mission which could provide a precise measurement of the power spectrum down to scales of 10 arcminutes, allowing us to decode essentially all of the information that it contains [26].

20. COSMIC RAYS

Written 1995 by T.K. Gaisser and T. Stanev

20.1. Primary spectra

The cosmic radiation incident at the top of the terrestrial atmosphere includes all stable charged particles and nuclei with lifetimes of order 10^6 years or longer. Technically, "primary" cosmic rays are those particles accelerated at astrophysical sources and "secondaries" are those particles produced in interaction of the primaries with interstellar gas. Thus electrons, protons and helium, as well as carbon, oxygen, iron, and other nuclei synthesized in stars, are primaries. Nuclei such as lithium, beryllium, and boron (which are not abundant end-products of stellar nucleosynthesis) are secondaries. Antiprotons and positrons are partly, if not entirely, secondaries, but the fraction of these particles that may be primary is a question of current interest.

Apart from particles associated with solar flares, the cosmic radiation comes from outside the solar system. The incoming charged particles are "modulated" by the solar wind, the expanding magnetized plasma generated by the Sun, which decelerates and partially excludes the lower energy galactic cosmic rays from the inner solar system. There is a significant anticorrelation between solar activity (which has an eleven-year cycle) and the intensity of the cosmic rays with energies below about 10 GeV. In addition, the lower-energy cosmic rays are affected by the geomagnetic field, which they must penetrate to reach the top of the atmosphere. Thus the intensity of any component of the cosmic radiation in the GeV range depends both on the location and time.

There are four different ways to describe the spectra of the components of the cosmic radiation: (1) By particles per unit rigidity. Propagation (and probably also acceleration) through cosmic magnetic fields depends on gyroradius or magnetic rigidity, R, which is gyroradius multiplied by the magnetic field strength:

$$R = \frac{p\,c}{Z\,e} = r_L\,B\ . \tag{20.1}$$

(2) By particles per energy-per-nucleon. Fragmentation of nuclei propagating through the interstellar gas depends on energy per nucleon, since that quantity is approximately conserved when a nucleus breaks up on interaction with the gas. (3) By nucleons per energy-per-nucleon. Production of secondary cosmic rays in the atmosphere depends on the intensity of nucleons per energy-per-nucleon, approximately independently of whether the incident nucleons are free protons or bound in nuclei. (4) By particles per energy-per-nucleus. Air shower experiments that use the atmosphere as a calorimeter generally measure a quantity that is related to total energy per particle.

The units of differential intensity I are $[\mathrm{cm}^{-2}\mathrm{s}^{-1}\mathrm{sr}^{-1}\mathcal{E}^{-1}]$, where \mathcal{E} represents the units of one of the four variables listed above.

The intensity of primary nucleons in the energy range from several ${\rm GeV}$ to somewhat beyond 100 ${\rm TeV}$ is given approximately by

$$I_N(E) \approx 1.8 E^{-\alpha} \frac{\text{nucleons}}{\text{cm}^2 \text{ s sr GeV}},$$
 (20.2)

where E is the energy-per-nucleon (including rest mass energy) and $\alpha \ (\equiv \gamma+1)=2.7$ is the differential spectral index of the cosmic ray flux and γ is the integral spectral index. About 79% of the primary nucleons are free protons and about 70% of the rest are nucleons bound in helium nuclei. The fractions of the primary nuclei are nearly constant over this energy range (possibly with small but interesting variations). Fractions of both primary and secondary incident nuclei are listed in Table 20.1. Figure 20.1 [1] shows the major components as a function of energy at a particular epoch of the solar cycle.

The spectrum of electrons and positrons incident at the top of the atmosphere is steeper than the spectra of protons and nuclei, as shown in Fig. 20.2 [2]. The positron fraction is about 10% in the region in which it is measured (< 20 GeV), but it is not yet fully understood [5].

Above 10 GeV the fraction of antiprotons to protons is about 10^{-4} , and there is evidence for the kinematic suppression at lower

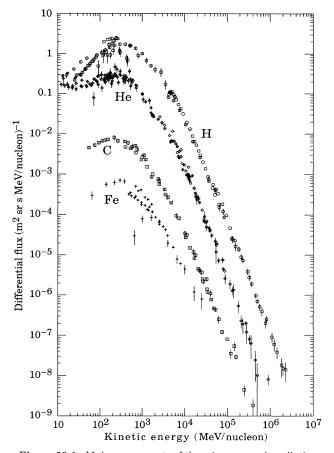

Figure 20.1: Major components of the primary cosmic radiation (from Ref. 1).

Table 20.1: Relative abundances F of cosmic-ray nuclei at 10.6 GeV/nucleon normalized to oxygen ($\equiv 1$) [3]. The oxygen flux at kinetic energy of 10.6 GeV/nucleon is 3.26×10^{-6} cm⁻² s⁻¹ sr⁻¹ (GeV/nucleon)⁻¹. Abundances of hydrogen and helium are from Ref. 4.

Z	Element	F	Z	Element	F
1	Н	730	13-14	Al-Si	0.19
2	He	34	15-16	P-S	0.03
3-5	Li-B	0.40	17 - 18	Cl-Ar	0.01
6-8	C-O	2.20	19 - 20	K-Ca	0.02
9-10	F-Ne	0.30	21 - 25	Sc-Mn	0.05
11-12	Na-Mg	0.22	26 - 28	Fe-Ni	0.12

energy expected for secondary antiprotons [5]. There is at this time no evidence for a significant primary component of antiprotons.

20.2. Cosmic rays in the atmosphere

Figure 20.3 shows the vertical fluxes of the major cosmic ray components in the atmosphere in the energy region where the particles are most numerous (except for electrons, which are most numerous near their critical energy, which is about 81 MeV in air). Except for protons and electrons near the top of the atmosphere, all particles are produced in interactions of the primary cosmic rays in the air. Muons and neutrinos are products of the decay of charged mesons, while electrons and photons originate in decays of neutral mesons.

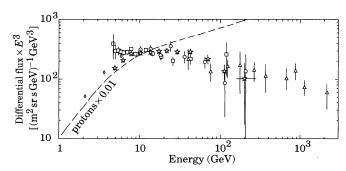

Figure 20.2: Differential spectrum of electrons plus positrons multiplied by E^3 (from Ref. 2).

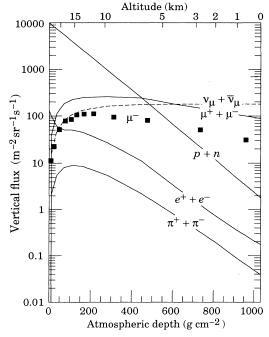

Figure 20.3: Vertical fluxes of cosmic rays in the atmosphere with E>1 GeV estimated from the nucleon flux of Eq. (20.2). The points show measurements of negative muons with $E_{\mu}>1$ GeV [7].

Most measurements are made at ground level or near the top of the atmosphere, but there are also measurements of muons and electrons from airplanes and balloons. Fig. 20.3 includes a recent measurement of negative muons [7]. Since $\mu^+(\mu^-)$ are produced in association with $\nu_\mu(\overline{\nu}_\mu)$, the measurement of muons near the maximum of the intensity curve for the parent pions serves to calibrate the atmospheric ν_μ beam [6]. Because muons typically lose almost two GeV in passing through the atmosphere, the comparison near the production altitude is important for the sub-GeV range of $\nu_\mu(\overline{\nu}_\mu)$ energies.

The flux of cosmic rays through the atmosphere is described by a set of coupled cascade equations with boundary conditions at the top of the atmosphere to match the primary spectrum. Numerical or Monte Carlo calculations are needed to account accurately for decay and energy-loss processes, and for the energy-dependences of the cross sections and of the primary spectral index γ . Approximate analytic solutions are, however, useful in limited regions of energy [8]. For example, the vertical intensity of nucleons at depth X (g cm⁻²) in the atmosphere is given by

$$I_N(E,X) \approx I_N(E,0) e^{-X/\Lambda}$$
, (20.3)

where Λ is the attenuation length of nucleons in air.

The corresponding expression for the vertical intensity of charged pions with energy $E_\pi\ll\epsilon_\pi=115$ GeV is

$$I_{\pi}(E_{\pi},X) \approx \frac{Z_{N\pi}}{\lambda_N} I_N(E_{\pi},0) e^{-X/\Lambda} \frac{X E_{\pi}}{\epsilon_{\pi}}$$
 (20.4)

This expression has a maximum at $t=\Lambda\approx 120~{\rm g~cm^{-2}}$, which corresponds to an altitude of 15 kilometers. The quantity $Z_{N\pi}$ is the spectrum-weighted moment of the inclusive distribution of charged pions in interactions of nucleons with nuclei of the atmosphere. The intensity of low-energy pions is much less than that of nucleons because $Z_{N\pi}\approx 0.079$ is small and because most pions with energy much less than the critical energy ϵ_{π} decay rather than interact.

20.3. Cosmic rays at the surface

20.3.1. Muons: Muons are the most numerous charged particles at sea level (see Fig. 20.3). Most muons are produced high in the atmosphere (typically 15 km) and lose about 2 GeV to ionization before reaching the ground. Their energy and angular distribution reflect a convolution of production spectrum, energy loss in the atmosphere, and decay. For example, $E_{\mu}=2.4~{\rm GeV}$ muons have a decay length of 15 km, which is reduced to 8.7 km by energy loss. The mean energy of muons at the ground is ≈ 4 GeV. The energy spectrum is almost flat below 1 GeV, steepens gradually to reflect the primary spectrum in the 10-100 GeV range, and steepens further at higher energies because pions with $E_{\pi} > \epsilon_{\pi} \approx 115$ GeV tend to interact in the atmosphere before they decay. Asymptotically $(E_{\mu} \gg 1 \text{ TeV})$, the energy spectrum of atmospheric muons is one power steeper than the primary spectrum. The integral intensity of vertical muons above 1 GeV/c at sea level is $\approx 70 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ [9,10]. Experimentalists are familiar with this number in the form $I \approx 1 \text{ cm}^{-2} \text{ min}^{-1}$ for horizontal detectors.

The overall angular distribution of muons at the ground is $\propto \cos^2 \theta$, which is characteristic of muons with $E_{\mu} \sim 3$ GeV. At lower energy the angular distribution becomes increasingly steeper, while at higher energy it flattens and approaches a $\sec \theta$ distribution for $E_{\mu} \gg \epsilon_{\pi}$ and $\theta < 70^{\circ}$.

Figure 20.4 shows the muon energy spectrum at sea level for two angles. At large angles low energy muons decay before reaching the surface and high energy pions decay before they interact, thus the average muon energy increases. An approximate extrapolation formula valid when muon decay is negligible $(E_{\mu}>100/\cos\theta~{\rm GeV})$ and the curvature of the Earth can be neglected $(\theta<70^{\circ})$ is

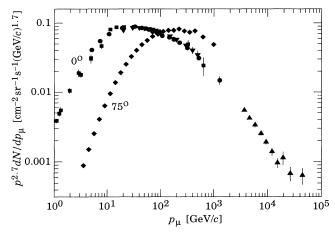

Figure 20.4: Spectrum of muons at $\theta = 0^{\circ}$ (■ [12], ● [13], ▼ [14], ▲ [15]), and $\theta = 75^{\circ}$ ♦ [16]).

$$\frac{dN_{\mu}}{dE_{\mu}} \approx \frac{0.14 E^{-2.7}}{\text{cm}^2 \text{ s sr GeV}}$$

$$\times \left\{ \frac{1}{1 + \frac{1.1 E_{\mu} \cos \theta}{115 \text{ GeV}}} + \frac{0.054}{1 + \frac{1.1 E_{\mu} \cos \theta}{850 \text{ GeV}}} \right\} , \tag{20.5}$$

where the two terms give the contribution of pions and charged kaons. Eq. (20.5) neglects a small contribution from charm and heavier flavors which is negligible except at very high energy [17].

The muon charge ratio reflects the excess of π^+ over π^- in the forward fragmentation region of proton initiated interactions together with the fact that there are more protons than neutrons in the primary spectrum. The charge ratio is between 1.2 and 1.3 from 250 MeV up to 100 GeV [9].

20.3.2. Electromagnetic component: At the ground, this component consists of electrons, positrons, and photons primarily from electromagnetic cascades initiated by decay of neutral and charged mesons. Muon decay is the dominant source of low-energy electrons at sea level. Decay of neutral pions is more important at high altitude or when the energy threshold is high. Knock-on electrons also make a small contribution at low energy [11]. The integral vertical intensity of electrons plus positrons is very approximately 30, 6, and $0.2~\mathrm{m}^{-2}\mathrm{s}^{-1}\mathrm{sr}^{-1}$ above 10, 100, and 1000 MeV respectively [10,18], but the exact numbers depend sensitively on altitude, and the angular dependence is complex because of the different altitude dependence of the different sources of electrons [11,18,19]. The ratio of photons to electrons plus positrons is approximately 1.3 above a GeV and 1.7 below the critical energy [19].

20.3.3. *Protons*: Nucleons above 1 GeV/c at ground level are degraded remnants of the primary cosmic radiation. The intensity is approximately represented by Eq. (20.3) with the replacement $t \to t/\cos\theta$ for $\theta < 70^\circ$ and an attenuation length $\Lambda = 123$ g cm⁻². At sea level, about 1/3 of the nucleons in the vertical direction are neutrons (up from $\approx 10\%$ at the top of the atmosphere as the n/p ratio approaches equilibrium). The integral intensity of vertical protons above 1 GeV/c at sea level is $\approx 0.9 \text{ m}^{-2} \text{s}^{-1} \text{sr}^{-1}$ [10,20].

20.4. Cosmic rays underground

Only muons and neutrinos penetrate to significant depths underground. The muons produce tertiary fluxes of photons, electrons, and hadrons.

20.4.1. *Muons*: As discussed in Section 22.9 of this *Review*, muons lose energy by ionization and by radiative processes: bremsstrahlung, direct production of e^+e^- pairs, and photonuclear interactions. The total muon energy loss may be expressed as a function of the amount of matter traversed as

$$-\frac{dE_{\mu}}{dX} = a + b E_{\mu} , \qquad (20.6)$$

where a is the ionization loss and b is the fractional energy loss by the three radiation processes. Both are slowly varying functions of energy. The quantity $\epsilon \equiv a/b$ (≈ 500 GeV in standard rock) defines a critical energy below which continuous ionization loss is more important the radiative losses. Table 20.2 shows a and b values for standard rock as a function of muon energy. The second column of Table 20.2 shows the muon range in standard rock ($A=22,Z=11,\rho=2.65$ g cm⁻³). These parameters are quite sensitive to the chemical composition of the rock, which must be evaluated for each experimental location.

The intensity of muons underground can be estimated from the muon intensity in the atmosphere and their rate of energy loss. To the extent that the mild energy dependence of a and b can be neglected, Eq. (20.6) can be integrated to provide the following relation between the energy $E_{\mu,0}$ of a muon at production in the atmosphere and its average energy E_{μ} after traversing a thickness X of rock (or ice or water):

$$E_{\mu} = (E_{\mu,0} + \epsilon) e^{-bX} - \epsilon . {(20.7)}$$

Table 20.2: Average muon range R and energy loss parameters calculated for standard rock. Range is given in km-water-equivalent, or 10^5 g cm⁻².

E_{μ} GeV	R km.w.e.	$\begin{array}{c} a \\ {\rm MeVg^{-1}cm^2} \end{array}$	b_{pair}		$b_{ m nucl}$ $-1 m cm^2$	
10	0.05	2.15	0.73	0.74	0.45	1.91
100	0.41	2.40	1.15	1.56	0.41	3.12
1000	2.42	2.58	1.47	2.10	0.44	4.01
10000	6.30	2.76	1.64	2.27	0.50	4.40

Especially at high energy, however, fluctuations are important and an accurate calculation requires a simulation that accounts for stochastic energy-loss processes [21].

Fig. 20.5 shows the vertical muon intensity versus depth. In constructing this "depth-intensity curve," each group has taken account of the angular distribution of the muons in the atmosphere, the map of the overburden at each detector, and the properties of the local medium in connecting measurements at various slant depths and zenith angles to the vertical intensity. Use of data from a range of angles allows a fixed detector to cover a wide range of depths. The flat portion of the curve is due to muons produced locally by charged-current interactions of ν_{μ} .

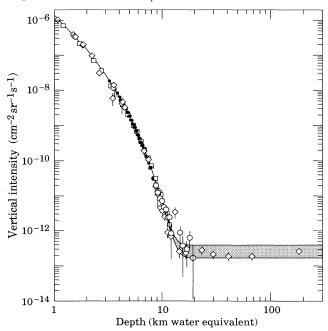

Figure 20.5: Vertical muon intensity vs. depth (1 km.w.e. = 10⁵ g cm⁻² of standard rock). The experimental data are from: ◊: the compilations of Crouch [29], □: Baksan [30], ○: LVD [31], ●: MACRO [32], ■: Frejus [33]. The shaded area at large depths represents neutrino induced muons of energy above 2 GeV. The upper line is for horizontal neutrino-induced muons, the lower one for vertically upward muons.

The energy spectrum of atmospheric muons underground can be estimated from Eq. (20.7). The muon energy spectrum at slant depth X is

$$\frac{dN_{\mu}(X)}{dE_{\mu}} = \frac{dN_{\mu}}{dE_{\mu,0}} e^{bX} , \qquad (20.8)$$

where $E_{\mu,0}$ is the solution of Eq. (20.7). For $X \ll b^{-1} \approx 2.5$ km water equivalent, $E_{\mu,0} \approx E_{\mu}(X) + aX$. Thus at shallow depths the differential muon energy spectrum is approximately constant for

 $E_{\mu} < aX$ and steepens to reflect the surface muon spectrum for $E_{\mu} > aX$. For $X \gg b^{-1}$ the differential spectrum underground is again constant for small muon energies but steepens to reflect the surface muon spectrum for $E_{\mu} > \epsilon \approx 0.5$ TeV. In this regime the shape is independent of depth although the intensity decreases exponentially with depth.

20.4.2. Neutrinos: Because neutrinos have small interaction cross sections, measurements of atmospheric neutrinos require a deep detector to avoid backgrounds. There are two types of measurements: contained (or semi-contained) events, in which the vertex is determined to originate inside the detector, and neutrino-induced muons. The latter are muons that enter the detector from zenith angles so large (e.g., nearly horizontal or upward) that they cannot be muons produced in the atmosphere. In neither case is the neutrino flux measured directly. What is measured is a convolution of the neutrino flux and cross section with the properties of the detector (which includes the surrounding medium in the case of entering muons).

Contained events reflect the neutrinos in the GeV region where the product of increasing cross section and decreasing flux is maximum. In this energy region the neutrino flux and its angular distribution depend on the geomagnetic location of the detector and to a lesser extent on the phase of the solar cycle. Naively, we expect $\nu_{\mu}/\nu_{e}=2$ from counting the neutrinos of the two flavors coming from the chain of pion and muon decay. This ratio is only slightly modified by the details of the decay kinematics. Experimental measurements have also to account for the ratio of $\overline{\nu}/\nu$, which have cross sections different by a factor of 3 in this energy range. In addition, detectors will generally have different efficiencies for detecting muon neutrinos and electron neutrinos. Even after correcting for these and other effects, some detectors [22,23] infer a ν_{μ}/ν_{e} ratio lower by $\approx 4\sigma$ from the expected value. (See Tables in the Particle Listings of this Review.) This effect is sometimes cited as possible evidence of neutrino oscillations and is a subject of current investigation. Figure 20.6 shows the data of Refs. 22,23 for the distributions of visible energy in electron-like and muon-like charged-current events, which appear to be nearly equal in number. Corrections for detection efficiencies and backgrounds are insufficient to account for the difference from the expected value of

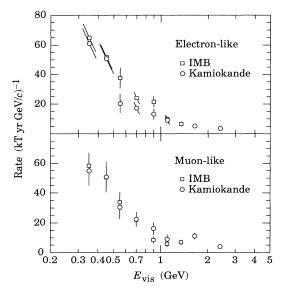

Figure 20.6: Contained neutrino interactions from IMB [23](\square) and Kamiokande [22].

Muons that enter the detector from outside after production in charged-current interactions of neutrinos naturally reflect a higher energy portion of the neutrino spectrum than contained events because the muon range increases with energy as well as the cross section. The relevant energy range is $\sim 10 < E_{\nu} < 1000$ GeV, depending somewhat

on angle. Like muons (see Eq. (20.5)), high energy neutrinos show a "secant theta" effect which causes the flux of horizontal neutrino induced muons to be approximately a factor two higher than the vertically upward flux. The upper and lower edges of the horizontal shaded region in Fig. 20.5 correspond to horizontal and vertical intensities of neutrino-induced muons. Table 20.3 gives the measured fluxes of neutrino induced muons.

Table 20.3: Measured fluxes $(10^{-13} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1})$ of neutrino-induced muons as a function of the minimum muon energy E_{μ} .

20.5. Air showers

So far we have discussed inclusive or uncorrelated fluxes of various components of the cosmic radiation. An air shower is caused by a single cosmic ray with energy high enough for its cascade to be detectable at the ground. The shower has a hadronic core, which acts as a collimated source of electromagnetic subshowers, generated mostly from $\pi^0 \to \gamma \gamma$. The resulting electrons and positrons are the most numerous particles in the shower. The number of muons, produced by decays of charged mesons, is an order of magnitude lower.

Air showers spread over a large area on the ground, and arrays of detectors operated for long times are useful for studying cosmic rays with primary energy $E_0>100~{\rm TeV}$, where the low flux makes measurements with small detectors in balloons and satellites difficult.

Greisen [46] gives the following approximate expressions for the numbers and lateral distributions of particles in showers at ground level. The total number of muons N_{μ} with energies above 1 GeV is

$$N_{\mu}(> 1 \text{ GeV}) \approx 0.95 \times 10^5 \left(\frac{N_e}{10^6}\right)^{3/4} ,$$
 (20.9)

where N_e is the total number of charged particles in the shower (not just e^{\pm}). The number of muons per square meter, ρ_{μ} , as a function of the lateral distance r (in meters) from the center of the shower is

$$\rho_{\mu} = \frac{1.25 N_{\mu}}{2\pi \Gamma(1.25)} \left(\frac{1}{320}\right)^{1.25} r^{-0.75} \left(1 + \frac{r}{320}\right)^{-2.5} , \qquad (20.10)$$

where Γ is the gamma function. The number density of charged particles is

$$\rho_e = C_1(s, d, C_2) x^{(s-2)} (1+x)^{(s-4.5)} (1+C_2 x^d) . \tag{20.11}$$

Here s, d, and C_2 are parameters in terms of which the overall normalization constant $C_1(s, d, C_2)$ is given by

$$C_1(s, d, C_2) = \frac{N_e}{2\pi r_1^2} \left[B(s, 4.5 - 2s) + C_2 B(s + d, 4.5 - d - 2s) \right]^{-1},$$
(20.12)

where B(m,n) is the beta function. The values of the parameters depend on shower size (N_e) , depth in the atmosphere, identity of the primary nucleus, etc. For showers with $N_e\approx 10^6$ at sea level, Greisen uses s=1.25, d=1, and $C_2=0.088$. Finally, x is r/r_1 , where r_1 is the Molière radius, which depends on the density of the atmosphere and hence on the altitude at which showers are detected. At sea level $r_1\approx 78$ m. It increases with altitude.

The lateral spread of a shower is determined largely by Coulomb scattering of the many low-energy electrons and is characterized by

the Molière radius. The lateral spread of the muons (ρ_{μ}) is larger and depends on the transverse momenta of the muons at production as well as multiple scattering.

There are large fluctuations in development from shower to shower, even for showers of the same energy and primary mass—especially for small showers, which are usually well past maximum development when observed at the ground. Thus the shower size N_e and primary energy E_0 are only related in an average sense, and even this relation depends on depth in the atmosphere. One estimate of the relation is [35]

$$E_0 \sim 3.9 \times 10^6 \text{ GeV } (N_e/10^6)^{0.9}$$
 (20.13)

for vertical showers with $10^{14} < E < 10^{17}$ eV at 920 g cm⁻² (965 m above sea level). Because of fluctuations, N_e as a function of E_0 is not the inverse of Eq. (20.13). As E_0 increases the shower maximum (on average) moves down into the atmosphere and the relation between N_e and E_0 changes. At the maximum of shower development, there are approximately 2/3 particles per GeV of primary energy.

Detailed simulations and cross-calibrations between different types of detectors are necessary to establish the primary energy spectrum from air-shower experiments [35,36]. Figure 20.7 shows the "all-particle" spectrum. In establishing this spectrum, efforts have been made to minimize the dependence of the analysis on the primary composition. In the energy range above 10^{17} eV, the Fly's Eye technique [48] is particularly useful because it can establish the primary energy in a model-independent way by observing most of the longitudinal development of each shower, from which E_0 is obtained by integrating the energy deposition in the atmosphere.

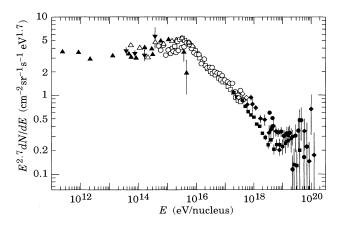

Figure 20.7: The all-particle spectrum: \blacktriangle [37], \blacktriangledown [38], \triangle [39], \Box [40], \bigcirc [35], \blacksquare [48], \spadesuit [42], \spadesuit [43].

In Fig. 20.7 the differential energy spectrum has been multiplied by $E^{2.7}$ in order to display the features of the steep spectrum that are otherwise difficult to discern. The steepening that occurs between 10^{15} and 10^{16} eV is known as the *knee* of the spectrum. The feature between 10^{18} and 10^{19} eV is called the *ankle* of the spectrum. Both these features are the subject of intense interest at present [44].

The ankle has the classical characteristic shape [45] of a higher energy population of particles overtaking a lower energy population. A possible interpretation is that the higher energy population represents cosmic rays of extragalactic origin. If this is the case and if the cosmic rays are cosmological in origin, then there should be a cutoff around 5×10^{19} eV, resulting from interactions with the microwave background [46,47]. It is therefore of special interest that several events have been assigned energies above 10^{20} eV [48,49,50].

If the cosmic ray spectrum below 10^{18} eV is of galactic origin, the knee could reflect the fact that some (but not all) cosmic accelerators have reached their maximum energy. Some types of expanding supernova remnants, for example, are estimated not to be able to accelerate particles above energies in the range of 10^{15} eV total energy

per particle. Effects of propagation and confinement in the galaxy [51] also need to be considered.

22. PASSAGE OF PARTICLES THROUGH MATTER

Revised May 1996.

22.1. Notation

Table 22.1: Summary of variables used in this section. The kinematic variables β and γ have their usual meanings.

	·	
Symbol	Definition	Units or Value
α	Fine structure constant	1/137.035 989 5(61)
M	Incident particle mass	${ m MeV}/c^2$
E	Incident particle energy γMc^2	MeV
T	Kinetic energy	MeV
$m_e c^2$	Electron mass $\times c^2$	$0.51099906(15)~{ m MeV}$
r_e	Classical electron radius	2.817 940 92(38) fm
	$e^2/4\pi\epsilon_0 m_e c^2$	
N_A	Avogadro's number	$6.0221367(36)\times10^{23}\mathrm{mol^{-1}}$
ze	Charge of incident particle	
Z	Atomic number of medium	
A	Atomic mass of medium	$g \text{ mol}^{-1}$
K/A	$4\pi N_A r_e^2 m_e c^2 / A$	$0.307075~{ m MeV~g^{-1}~cm^2}$
		for $A = 1 \text{ g mol}^{-1}$
I	Mean excitation energy	eV
δ	Density effect correction to ioni	
$\hbar\omega_p$	Plasma energy	$28.816\sqrt{\rho\langle Z/A\rangle} \text{ eV}^{(a)}$
	$\sqrt{4\pi N_e r_e^3} \ m_e c^2/lpha$	
w_j	Weight fraction of the j th elem	ent in a compound or mixture
n_{j}	\propto number of $j{\rm th}$ kind of atoms	in a compound or mixture
X_0	Radiation length	$\mathrm{g}^{-1}~\mathrm{cm}^2$
_	$4\alpha re^2 N_A/A$	$(716.408 \text{ g cm}^{-2})^{-1}$
		for $A = 1 \text{ g mol}^{-1}$
E_c	Critical energy	MeV
E_s	Scale energy $\sqrt{4\pi/\alpha} \ m_e c^2$	$21.2052~\mathrm{MeV}$
R_M	Molière radius	$\mathrm{MeV}~\mathrm{g}^{-1}~\mathrm{cm}^2$

⁽a) For ρ in g cm⁻³.

$\textbf{22.2.} \quad \textbf{Ionization energy loss by heavy particles} \ \textbf{\scriptsize{[1-5]}}$

Moderately relativistic charged particles other than electrons lose energy in matter primarily by ionization. If the incident particle velocity βc is larger than that of orbital electrons ($\sim Z\alpha c$) and small enough that radiative effects do not dominate (for example, pion energy smaller than 100–200 GeV in iron), then the mean rate of energy loss (or stopping power) is given by the Bethe-Bloch equation,

$$-\frac{dE}{dx} = Kz^{2} \frac{Z}{A} \frac{1}{\beta^{2}} \left[\frac{1}{2} \ln \frac{2m_{e}c^{2}\beta^{2}\gamma^{2}T_{\text{max}}}{I^{2}} - \beta^{2} - \frac{\delta}{2} \right] . \tag{22.1}$$

Here $T_{\rm max}$ is the maximum kinetic energy which can be imparted to a free electron in a single collision, and the other variables are defined in Table 22.1. The units are chosen so that dx is measured in mass per unit area, e.g., in g cm⁻². The function as computed for pions on copper is shown by the solid curve in Fig. 22.1, and for pions on other materials in Fig. 22.2. A minor dependence on M at the highest energies is introduced through $T_{\rm max}$, but for all practical purposes in high-energy physics dE/dx in a given material is a function only of β . Except in hydrogen, particles of the same velocity have very similar rates of energy loss in different materials; there is a slow decrease in the rate of energy loss with increasing Z. The qualitative difference in stopping power behavior at high energies between a gas (He) and the other materials shown in Fig. 22.2 is due to the density effect correction, δ , discussed below. The stopping power functions are characterized by broad minima whose position drops from $\beta\gamma=3.5$ to 3.0 as Z goes from 7 to 100.

In practical cases, most relativistic particles (e.g., cosmic-ray muons) have energy loss rates close to the minimum, and are said to be minimum ionizing particles, or mip's.

Eq. (22.1) may be integrated to find the total range R for a particle which loses energy only through ionization. Since dE/dx depends only on β , R/M is a function of E/M or pc/M. In practice, range is a useful concept only for low-energy hadrons ($R \lesssim \lambda_I$, where λ_I is the nuclear interaction length), and for muons below a few hundred GeV (above which radiative effects dominate). R/M as a function of $\beta \gamma = pc/M$ is shown for a variety of materials in Fig. 22.3.

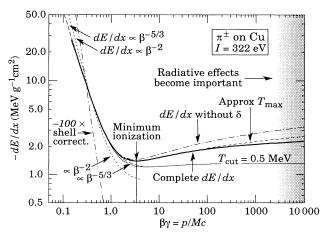

Figure 22.1: Energy loss rate in copper. The function without the density effect correction is also shown, as is the shell correction and two low-energy approximations.

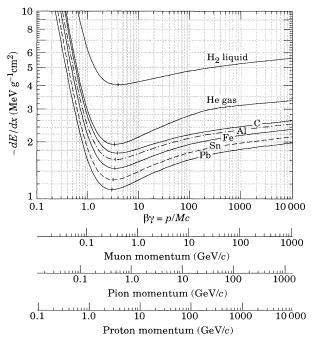

Figure 22.2: Energy loss rate in liquid (bubble chamber) hydrogen, gaseous helium, carbon, aluminum, tin, and lead.

For a particle with mass M and momentum $M\beta\gamma c$, T_{\max} is given by

$$T_{\text{max}} = \frac{2m_e c^2 \,\beta^2 \gamma^2}{1 + 2\gamma m_e / M + (m_e / M)^2} \ . \tag{22.2}$$

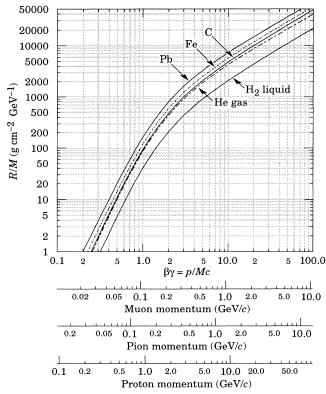

Figure 22.3: Range of heavy charged particles in liquid (bubble chamber) hydrogen, helium gas, carbon, iron, and lead. For example: For a K^+ whose momentum is 700 MeV/c, $\beta \gamma = 1.42$. For lead we read $R/M \approx 396$, and so the range is 195 g cm⁻².

It is usual [1,2] to make the "low-energy" approximation

 $T_{\rm max}=2m_ec^2\,\beta^2\gamma^2$, valid for $2\gamma m_e/M\ll 1$; this, in fact, is done implicitly in many standard references. For pion in copper, the error thus introduced into dE/dx is greater than 6% at 100 GeV. The correct expression should be used.

At energies of order 100 GeV, the maximum 4-momentum transfer to the electron can exceed 1 GeV/c, where structure effects significantly modify the cross sections. This problem has been investigated by J.D. Jackson [6], who concluded that for hadrons (but not for large nuclei) corrections to dE/dx are negligible below energies where radiative effects dominate. While the cross section for rare hard collisions is modified, the average stopping power, dominated by many softer collisions, is almost unchanged.

The mean excitation energy I is $(10\pm 1~{\rm eV})\times Z$ for elements heavier than oxygen. The values adopted by the ICRU for the chemical elements [7] are now in wide use; these are shown in Fig. 22.4. Machine-readable versions can also be found [8]. Given the availability of these constants and their variation with atomic structure, there seems little point to depending upon approximate formulae, as was done in the past.

A shell correction is often included in the square brackets of Eq. (22.1) [3,5,7], to correct for atomic binding having been neglected in calculating some of the contributions to Eq. (22.1). We show the Barkas form [3] in Fig. 22.1. For copper it contributes about 1% at $\beta\gamma=0.3$ (kinetic energy 6 MeV for a pion), and the correction decreases very rapidly with energy. While it is negligible for high-energy physics applications, this and other low-energy corrections must be taken into account at lower energies, such as those encountered in medical physics.

As the particle energy increases, its electric field flattens and extends, so that the distant-collision contribution to Eq. (22.1) increases as $\ln \beta \gamma$. However, real media become polarized, limiting the field extension and effectively truncating this part of the logarithmic

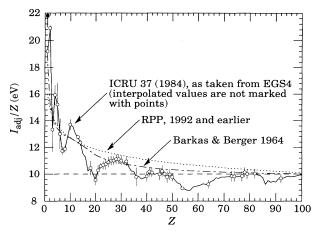

Figure 22.4: Excitation energies (divided by Z) as adopted by the ICRU [7]. Those based on measurement are shown by points with error flags; the interpolated values are simply joined. The solid point is for liquid H_2 ; the open point at 19.2 is for H_2 gas. Also shown are curves based on two approximate formulae.

rise [4,9-13]. At very high energies,

$$\delta/2 \to \ln(\hbar\omega_p/I) + \ln\beta\gamma - 1/2$$
, (22.3)

where $\delta/2$ is the density effect correction introduced in Eq. (22.1) and $\hbar\omega_p$ is the plasma energy defined in Table 22.1. A comparison with Eq. (22.1) shows that |dE/dx| then grows as $\ln\beta\gamma$ rather than $\ln\beta^2\gamma^2$, and that the mean excitation energy I is replaced by the plasma energy $\hbar\omega_p$. The stopping power as calculated with and without the density effect correction is shown in Fig. 22.1. Since the plasma frequency scales as the square root of the electron density, the correction is much larger for a liquid or solid than for a gas, as is illustrated by the examples in Fig. 22.2.

The remaining relativistic rise can be attributed to large energy transfers to a few electrons. If these escape or are otherwise accounted for separately, the energy deposited in an absorbing layer (in contrast to the energy lost by the particle) approaches a constant value, the Fermi plateau (see Sec. 22.3 below). The curve in Fig. 22.1 labeled " $T_{\rm cut}=0.5$ MeV" illustrates this behavior. At extreme energies (e.g., 400 GeV for muons or pions in iron), radiative effects become important. These are especially relevant for high-energy muons, as discussed in Sec. 22.9.

For particles moving more slowly than atomic electrons, the above discussion is inapplicable. At velocities $\alpha z \gtrsim \beta \gtrsim 10^{-3}$ or slightly lower, the total energy-loss rate is proportional to β , and non-ionizing nuclear recoil energy loss contributes substantially to the total [14]. For protons in silicon, $|dE/dx| = 61.2\,\beta$ GeV cm² g⁻¹ for $\beta < 0.005$; the peak occurs at $\beta = 0.0126$, where |dE/dx| = 522 MeV cm² g⁻¹. In neutron-scattering experiments, light output in scintillator has been observed for recoil protons with energies as low as 30 eV [15].

It is often stated that for $\beta \gtrsim z/137$, |dE/dx| falls as β^{-2} before reaching the broad minimum at $\beta\gamma \approx 3.0$ –3.5. In fact, the slope is nowhere this great, and $|dE/dx| \propto \beta^{-5/3}$ provides a very good approximation to the actual function out to $\beta\gamma > 1$. This behavior is shown in Fig. 22.1, along with the traditional β^{-2} proportionality.

The quantity $(dE/dx)\delta x$ is the mean energy loss via interaction with electrons in a layer of the medium with thickness δx . For finite δx , there are fluctuations in the actual energy loss. The distribution is skewed toward high values (the Landau tail) [1,16]. Only for a thick layer $[(dE/dx)\delta x\gg T_{\rm max}]$ is the distribution nearly Gaussian. The large fluctuations in the energy loss are due to the small number of collisions involving large energy transfers. The fluctuations are smaller for the so-called restricted energy loss rate, as discussed in Sec. 22.3 below.

A mixture or compound can be thought of as made up of thin layers of pure elements in the right proportion (Bragg additivity). In this case,

$$\frac{dE}{dx} = \sum w_j \left. \frac{dE}{dx} \right|_j \,, \tag{22.4}$$

where $dE/dx|_j$ is the mean rate of energy loss (in MeV g cm⁻²) in the jth element. Eq. (22.1) can be inserted into Eq. (22.4) to find expressions for $\langle Z/A \rangle$, $\langle I \rangle$, and $\langle \delta \rangle$; for example, $\langle Z/A \rangle = \sum w_j Z_j/A_j = \sum n_j Z_j/\sum n_j A_j$. However, $\langle I \rangle$ as defined this way is an underestimate, because in a compound electrons are more tightly bound than in the free elements, and $\langle \delta \rangle$ as calculated this way has little relevance, because it is the electron density which matters. If possible, one uses the tables given in Refs. 13 and 12, which include effective excitation energies and interpolation coefficients for calculating the density effect correction for the chemical elements and nearly 200 mixtures and compounds. If a compound or mixture is not found, then one uses the recipe for δ given in Ref. 10 (or Ref. 8), and calculates $\langle I \rangle$ according to the discussion in Ref. 11. (Note the "13%" rule!)

Ionization losses by electrons and positrons [12] are not discussed here. Above the critical energy, which is a few tens of MeV in most materials, bremsstrahlung is the dominant source of energy loss. This important case is discussed below. The contributions of various electron energy-loss processes in lead are shown in Fig. 23.4.

22.3. Restricted energy loss rates for relativistic ionizing particles

Fluctuations in energy loss are due mainly to the production of a few high-energy knock-on electrons. Practical detectors often measure the energy deposited, not the energy lost. When energy is carried off by energetic knock-on electrons, it is more appropriate to consider the mean energy loss excluding energy transfers greater than some cutoff $T_{\rm cut}$. The restricted energy loss rate is

$$-\frac{dE}{dx}\Big|_{T < T_{\text{cut}}} = Kz^2 \frac{Z}{A} \frac{1}{\beta^2} \left[\frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 T_{\text{upper}}}{I^2} - \frac{\beta^2}{2} \left(1 + \frac{T_{\text{upper}}}{T_{\text{max}}} \right) - \frac{\delta}{2} \right]$$
(22.5)

where $T_{\rm upper} = {\rm MIN}(T_{\rm cut}, T_{\rm max})$. This form agrees with the equation given in previous editions of this Review [17] for $T_{\rm cut} \ll T_{\rm max}$ but smoothly joins the normal Bethe-Bloch function (Eq. (22.1)) for $T_{\rm cut} > T_{\rm max}$.

22.4. Energetic knock-on electrons (δ rays)

The distribution of secondary electrons with kinetic energies $T\gg I$ is given by [1]

$$\frac{d^2N}{dTdx} = \frac{1}{2} K z^2 \frac{Z}{A} \frac{1}{\beta^2} \frac{F(T)}{T^2}$$
 (22.6)

for $I \ll T \leq T_{\rm max}$, where $T_{\rm max}$ is given by Eq. (22.2). The factor F is spin-dependent, but is about unity for $T \ll T_{\rm max}$. For spin-0 particles $F(T) = (1-\beta^2 T/T_{\rm max})$; forms for spins 1/2 and 1 are also given by Rossi [1]. When Eq. (22.6) is integrated from $T_{\rm cut}$ to $T_{\rm max}$,one obtains the difference between Eq. (22.1) and Eq. (22.5). For incident electrons, the indistinguishability of projectile and target means that the range of T extends only to half the kinetic energy of the incident particle. Additional formulae are given in Ref. 18. Equation (22.6) is inaccurate for T close to I: for $2I \lesssim T \lesssim 10I$, the $1/T^2$ dependence above becomes approximately $T^{-\eta}$, with $3 \lesssim \eta \lesssim 5$ [19].

22.5. Ionization yields

Physicists frequently relate total energy loss to the number of ion pairs produced near the particle's track. This relation becomes complicated for relativistic particles due to the wandering of energetic knock-on electrons whose ranges exceed the dimensions of the fiducial volume. For a qualitative appraisal of the nonlocality of energy deposition in various media by such modestly energetic knock-on electrons, see Ref. 20. The mean local energy dissipation per local ion pair produced, W, while essentially constant for relativistic particles, increases at slow particle speeds [21]. For gases, W can be surprisingly sensitive to trace amounts of various contaminants [21]. Furthermore, ionization yields in practical cases may be greatly influenced by such factors as subsequent recombination [22].

22.6. Multiple scattering through small angles

A charged particle traversing a medium is deflected by many small-angle scatters. Most of this deflection is due to Coulomb scattering from nuclei, and hence the effect is called multiple Coulomb scattering. (However, for hadronic projectiles, the strong interactions also contribute to multiple scattering.) The Coulomb scattering distribution is well represented by the theory of Molière [23]. It is roughly Gaussian for small deflection angles, but at larger angles (greater than a few θ_0 , defined below) it behaves like Rutherford scattering, having larger tails than does a Gaussian distribution.

If we define

$$\theta_0 = \theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{2}} \theta_{\text{space}}^{\text{rms}}$$
 (22.7)

then it is sufficient for many applications to use a Gaussian approximation for the central 98% of the projected angular distribution, with a width given by [24,25]

$$\theta_0 = \frac{13.6 \text{ MeV}}{\beta cp} z \sqrt{x/X_0} \left[1 + 0.038 \ln(x/X_0) \right]. \tag{22.8}$$

Here p, βc , and z are the momentum, velocity, and charge number of the incident particle, and x/X_0 is the thickness of the scattering medium in radiation lengths (defined below). This value of θ_0 is from a fit to Molière distribution [23] for singly charged particles with $\beta=1$ for all Z, and is accurate to 11% or better for $10^{-3} < x/X_0 < 100$.

Eq. (22.8) describes scattering from a single material, while the usual problem involves the multiple scattering of a particle traversing many different layers and mixtures. Since it is from a fit to a Molière distribution, it is incorrect to add the individual θ_0 contributions in quadrature; the result is systematically too small. It is much more accurate to apply Eq. (22.8) once, after finding x and X_0 for the combined scatterer.

Lynch and Dahl have extended this phenomenological approach, fitting Gaussian distributions to a variable fraction of the Molière distribution for arbitrary scatterers [25], and achieve accuracies of 2% or better.

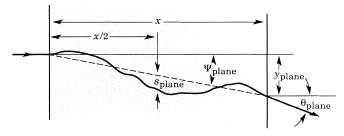

Figure 22.5: Quantities used to describe multiple Coulomb scattering. The particle is incident in the plane of the figure.

The nonprojected (space) and projected (plane) angular distributions are given approximately by [23]

$$\frac{1}{2\pi\,\theta_0^2}\,\exp\left(-\frac{\theta_{\rm space}^2}{2\theta_0^2}\right)d\Omega\;,\tag{22.9}$$

$$\frac{1}{\sqrt{2\pi}\,\theta_0} \exp\left(-\frac{\theta_{\text{plane}}^2}{2\theta_0^2}\right) d\theta_{\text{plane}} \,, \tag{22.10}$$

where θ is the deflection angle. In this approximation, $\theta_{\rm space}^2 \approx (\theta_{\rm plane,x}^2 + \theta_{\rm plane,y}^2)$, where the x and y axes are orthogonal to the direction of motion, and $d\Omega \approx d\theta_{\rm plane,x} d\theta_{\rm plane,y}$. Deflections into $\theta_{\rm plane,x}$ and $\theta_{\rm plane,y}$ are independent and identically distributed.

Figure 22.5 shows these and other quantities sometimes used to describe multiple Coulomb scattering. They are

$$\psi_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} \theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} \theta_0 , \qquad (22.11)$$

$$y_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} x \theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} x \theta_0$$
, (22.12)

$$s_{\text{plane}}^{\text{rms}} = \frac{1}{4\sqrt{3}} x \theta_{\text{plane}}^{\text{rms}} = \frac{1}{4\sqrt{3}} x \theta_0 . \qquad (22.13)$$

All the quantitative estimates in this section apply only in the limit of small $\theta_{\rm plane}^{\rm rms}$ and in the absence of large-angle scatters. The random variables $s,~\psi,~y,$ and θ in a given plane are distributed in a correlated fashion (see Sec. 27.1 of this Review for the definition of the correlation coefficient). Obviously, $y\approx x\psi$. In addition, y and θ have the correlation coefficient $\rho_{y\theta}=\sqrt{3}/2\approx 0.87.$ For Monte Carlo generation of a joint $(y_{\rm plane},\theta_{\rm plane})$ distribution, or for other calculations, it may be most convenient to work with independent Gaussian random variables (z_1,z_2) with mean zero and variance one, and then set

$$y_{\text{plane}} = z_1 x \,\theta_0 (1 - \rho_{y\theta}^2)^{1/2} / \sqrt{3} + z_2 \,\rho_{y\theta} x \,\theta_0 / \sqrt{3}$$
$$= z_1 x \,\theta_0 / \sqrt{12} + z_2 x \,\theta_0 / 2 ; \qquad (22.14)$$

$$\theta_{\text{plane}} = z_2 \, \theta_0 \ . \tag{22.15}$$

Note that the second term for $y_{\rm plane}$ equals $x\,\theta_{\rm plane}/2$ and represents the displacement that would have occurred had the deflection $\theta_{\rm plane}$ all occurred at the single point x/2.

For heavy ions the multiple Coulomb scattering has been measured and compared with various theoretical distributions [26].

22.7. Radiation length and associated quantities

In dealing with electrons and photons at high energies, it is convenient to measure the thickness of the material in units of the radiation length X_0 . This is the mean distance over which a high-energy electron loses all but 1/e of its energy by bremsstrahlung, and is the appropriate scale length for describing high-energy electromagnetic cascades. X_0 has been calculated and tabulated by Y.S. Tsai [27]:

$$\frac{1}{X_0} = 4\alpha r_e^2 \frac{N_A}{A} \left\{ Z^2 \left[L_{\rm rad} - f(Z) \right] + Z L'_{\rm rad} \right\}. \tag{22.16}$$

For A=1 g mol⁻¹, $4\alpha re^2 N_A/A=(716.408 \text{ g cm}^{-2})^{-1}$. $L_{\rm rad}$ and $L'_{\rm rad}$ are given in Table 22.2. The function f(Z) is an infinite sum, but for elements up to uranium can be represented to 4-place accuracy by

$$f(Z) = a^2 \left[(1+a^2)^{-1} + 0.20206 -0.0369 \, a^2 + 0.0083 \, a^4 - 0.002 \, a^6 \right] , \tag{22.17}$$

where $a = \alpha Z$ [28].

Table 22.2: Tsai's $L_{\rm rad}$ and $L'_{\rm rad}$, for use in calculating the radiation length in an element using Eq. (22.16).

Element	Z	$L_{ m rad}$	$L'_{ m rad}$
Н	1	5.31	6.144
${\rm He}$	2	4.79	5.621
Li	3	4.74	5.805
$_{ m Be}$	4	4.71	5.924
Others	> 4	$\ln(184.15Z^{-1/3})$	$\ln(1194Z^{-2/3})$

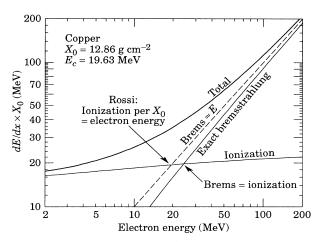

Figure 22.6: Two definitions of the critical energy E_c .

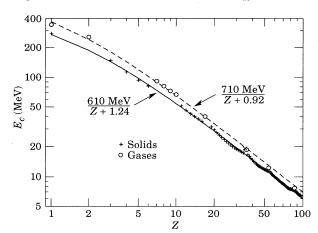

Figure 22.7: Electron critical energy for the chemical elements, using Rossi's definition [1]. The fits shown are for solids and liquids (solid line) and gases (dashed line). The rms deviation is 2.2% for the solids and 4.0% for the gases. (Computed with code supplied by A. Fassó.)

Although it is easy to use Eq. (22.16) to calculate X_0 , the functional dependence on Z is somewhat hidden. Dahl provides a compact fit to the data [29]:

$$X_0 = \frac{716.4 \text{ g cm}^{-2} A}{Z(Z+1) \ln(287/\sqrt{Z})}$$
 (22.18)

Results obtained with this formula agree with Tsai's values to better than 2.5% for all elements except helium, where the result is about 5% low.

The radiation length in a mixture or compound may be approxi-

$$1/X_0 = \sum w_j/X_j , \qquad (22.19)$$

where w_j and X_j are the fraction by weight and the radiation length for the jth element.

An electron loses energy by bremsstrahlung at a rate nearly proportional to its energy, while the ionization loss rate varies only logarithmically with the electron energy. The critical energy E_c is sometimes defined as the energy at which the two loss rates are equal [30]. Berger and Seltzer [30] also give the approximation $E_c = (800 \text{ MeV})/(Z+1.2)$. This formula has been widely quoted, and has been given in previous editions of this Review [17]. Among alternate definitions is that of Rossi [1], who defines the critical energy as the energy at which the ionization loss per radiation length is equal to the electron energy. Equivalently, it is the same as the first definition with the approximation $|dE/dx|_{\text{brems}} \approx E/X_0$. These definitions are illustrated in the case of copper in Fig. 22.6 [31].

The accuracy of approximate forms for E_c has been limited by the failure to distinguish between gases and solid or liquids, where there is a substantial difference in ionization at the relevant energy because of the density effect. We distinguish these two cases in Fig. 22.7. Fits were also made with functions of the form $a/(Z+b)^{\alpha}$, but α was essentially unity.

The transverse development of electromagnetic showers in different materials scales fairly accurately with the *Molière radius* R_M , given by [32,33]

$$R_M = X_0 E_s / E_c , (22.20)$$

where $E_s \approx 21$ MeV (see Table 22.1), and the Rossi definition of E_c is used.

In a material containing a weight fraction w_j of the element with critical energy E_{cj} and radiation length X_j , the Molière radius is given by

$$\frac{1}{R_M} = \frac{1}{E_s} \sum \frac{w_j E_{cj}}{X_j} \ . \tag{22.21}$$

For very high-energy photons, the total e^+e^- pair-production cross section is approximately

$$\sigma = \frac{7}{9}(A/X_0N_A) , \qquad (22.22)$$

where A is the atomic weight of the material and N_A is Avogadro's number. Equation Eq. (22.22) is accurate to within a few percent down to energies as low as 1 GeV. The cross section decreases at lower energies, as shown in Fig. 23.4 of this *Review*. As the energy decreases, a number of other processes become important, as is shown in Fig. 23.3 of this *Review*.

22.8. Electromagnetic cascades

When a high-energy electron or photon is incident on a thick absorber, it initiates an electromagnetic cascade as pair production and bremsstrahlung generate more electrons and photons with lower energy. The longitudinal development is governed by the high-energy part of the cascade, and therefore scales as the radiation length in the material. Electron energies eventually fall below the critical energy, and then dissipate their energy by ionization and excitation rather than by the generation of more shower particles. In describing shower behavior, it is therefore convenient to introduce the scale variables

$$t = x/X_0$$

$$y = E/E_c , (22.23)$$

so that distance is measured in units of radiation length and energy in units of critical energy.

Longitudinal profiles for an EGS4 [8] simulation of a 30 GeV electron-induced cascade in iron are shown in Fig. 22.8. The number of particles crossing a plane (very close to Rossi's II function [1]) is sensitive to the cutoff energy, here chosen as a total energy of 1.5 MeV for both electrons and photons. The electron number falls off more quickly than energy deposition. This is because, with increasing depth, a larger fraction of the cascade energy is carried by photons.

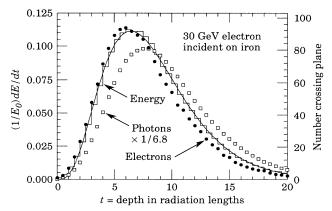

Figure 22.8: An EGS4 simulation of a 30 GeV electron-induced cascade in iron. The histogram shows fractional energy deposition per radiation length, and the curve is a gamma-function fit to the distribution. Circles indicate the number of electrons with total energy greater than 1.5 MeV crossing planes at $X_0/2$ intervals (scale on right) and the squares the number of photons with $E \geq 1.5$ MeV crossing the planes (scaled down to have same area as the electron distribution).

Exactly what a calorimeter measures depends on the device, but it is not likely to be exactly any of the profiles shown. In gas counters it may be very close to the electron number, but in glass Čerenkov detectors and other devices with "thick" sensitive regions it is closer to the energy deposition (total track length). In such detectors the signal is proportional to the "detectable" track length T_d , which is in general less than the total track length T_d . Practical devices are sensitive to electrons with energy above some detection threshold E_d , and $T_d = T \, F(E_d/E_c)$. An analytic form for $F(E_d/E_c)$ obtained by Rossi [1] is given by Fabjan [34]; see also Amaldi [35].

The mean longitudinal profile of the energy deposition in an electromagnetic cascade is reasonably well described by a gamma distribution [36]:

$$\frac{dE}{dt} = E_0 b \frac{(bt)^{a-1} e^{-bt}}{\Gamma(a)}$$
 (22.24)

The maximum $t_{\rm max}$ occurs at (a-1)/b. We have made fits to shower profiles in elements ranging from carbon to uranium, at energies from 1 GeV to 100 GeV. The energy deposition profiles are well described by Eq. (22.24) with

$$t_{\text{max}} = (a-1)/b = 1.0 \times (\ln y + C_i), \qquad j = e, \gamma,$$
 (22.25)

where $C_e = -0.5$ for electron-induced cascades and $C_{\gamma} = +0.5$ for photon-induced cascades. To use Eq. (22.24), one finds (a-1)/b from Eq. (22.25) and Eq. (22.23), then finds a either by assuming $b \approx 0.5$ or by finding a more accurate value from Fig. 22.9. The results are very similar for the electron number profiles, but there is some dependence on the atomic number of the medium. A similar form for the electron number maximum was obtained by Rossi in the context of his "Approximation B," [1] (see Fabjan's review in Ref. 34), but with $C_e = -1.0$ and $C_{\gamma} = -0.5$; we regard this as superseded by the EGS4 result.

The "shower length" $X_s=X_0/b$ is less conveniently parametrized, since b depends upon both Z and incident energy, as shown in Fig. 22.9. As a corollary of this Z dependence, the number of electrons crossing a plane near shower maximum is underestimated using Rossi's approximation for carbon and seriously overestimated for uranium. Essentially the same b values are obtained for incident electrons and photons. For many purposes it is sufficient to take $b\approx 0.5$.

The gamma distribution is very flat near the origin, while the EGS4 cascade (or a real cascade) increases more rapidly. As a result Eq. (22.24) fails badly for about the first two radiation lengths; it was necessary to exclude this region in making fits.

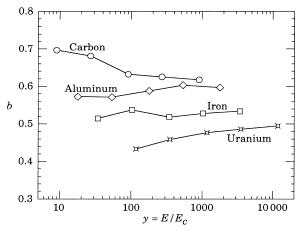

Figure 22.9: Fitted values of the scale factor b for energy deposition profiles obtained with EGS4 for a variety of elements for incident electrons with $1 \le E_0 \le 100$ GeV. Values obtained for incident photons are essentially the same.

Because fluctuations are important, Eq. (22.24) should be used only in applications where average behavior is adequate. Grindhammer $et\ al.$ have developed fast simulation algorithms in which the variance and correlation of a and b are obtained by fitting Eq. (22.24) to individually simulated cascades, then generating profiles for cascades using a and b chosen from the correlated distributions [37].

Measurements of the lateral distribution in electromagnetic cascades are shown in Refs. 32 and 33. On the average, only 10% of the energy lies outside the cylinder with radius R_M . About 99% is contained inside of $3.5R_M$, but at this radius and beyond composition effects become important and the scaling with R_M fails. The distributions are characterized by a narrow core, and broaden as the shower develops. They are often represented as the sum of two Gaussians, and Grindhammer [37] describes them with the function

$$f(r) = \frac{2r R^2}{(r^2 + R^2)^2} , \qquad (22.26)$$

where R is a phenomenological function of x/X_0 and $\ln E$.

22.9. Muon energy loss at high energy

At sufficiently high energies, radiative processes become more important than ionization for all charged particles. For muons and pions in materials such as iron, this "critical energy" occurs at several hundred GeV. Radiative effects dominate the energy loss of energetic muons found in cosmic rays or produced at the newest accelerators. These processes are characterized by small cross sections, hard spectra, large energy fluctuations, and the associated generation of electromagnetic and (in the case of photonuclear interactions) hadronic showers [40–47]. As a consequence, at these energies the treatment of energy loss as a uniform and continuous process is for many purposes inadequate.

It is convenient to write the average rate of muon energy loss as [38]

$$-dE/dx = a(E) + b(E)E. (22.27)$$

Here a(E) is the ionization energy loss given by Eq. (22.1), and b(E) is the sum of e^+e^- pair production, bremsstrahlung, and photonuclear contributions. To the approximation that these slowly-varying functions are constant, the mean range x_0 of a muon with initial energy E_0 is given by

$$x_0 \approx (1/b) \ln(1 + E_0/E_{\mu c})$$
, (22.28)

where $E_{\mu c}=a/b$. Figure 22.10 shows contributions to b(E) for iron. Since $a(E)\approx 0.002$ GeV g⁻¹ cm², b(E)E dominates the energy loss

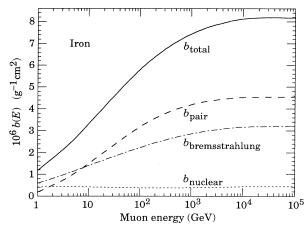

Figure 22.10: Contributions to the fractional energy loss by muons in iron due to e^+e^- pair production, bremsstrahlung, and photonuclear interactions, as obtained from Lohmann *et al.* [39].

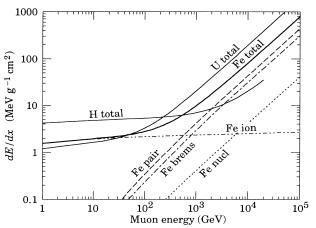

Figure 22.11: The average energy loss of a muon in hydrogen, iron, and uranium as a function of muon energy. Contributions to dE/dx in iron from ionization and the processes shown in Fig. 22.10 are also shown.

above several hundred GeV, where b(E) is nearly constant. The rate of energy loss for muons in hydrogen, uranium, and iron is shown in Fig. 22.11 [39].

The "muon critical energy" $E_{\mu c}$ can be defined more exactly as the energy at which radiative and ionization losses are equal, and can be found by solving $E_{\mu c} = a(E_{\mu c})/b(E_{\mu c})$. This definition corresponds to the solid-line intersection in Fig. 22.6, and is different from the Rossi definition we used for electrons. It serves the same function: below $E_{\mu c}$ ionization losses dominate, and above $E_{\mu c}$ dominate. The dependence of $E_{\mu c}$ on atomic number Z is shown in Fig. 22.12.

The radiative cross sections are expressed as functions of the fractional energy loss ν . The bremsstrahlung cross section goes roughly as $1/\nu$ over most of the range, while for the pair production case the distribution goes as ν^{-3} to ν^{-2} (see Ref. 50). "Hard" losses are therefore more probable in bremsstrahlung, and in fact energy losses due to pair production may very nearly be treated as continuous. The calculated momentum distribution of an incident 1 TeV/c muon beam after it crosses 3 m of iron is shown in Fig. 22.13. The most probable loss is 9 GeV, or 3.8 MeV g⁻¹cm². The full width at half maximum is 7 GeV/c, or 0.7%. The radiative tail is almost entirely due to bremsstrahlung; this includes most of the 10% that lost more than 2.8% of their energy. Most of the 3.3% that lost more than 10% of their incident energy experienced photonuclear interactions, which are concentrated in rare, relatively hard collisions. The latter can exceed nominal detector resolution [51], necessitating the reconstruction

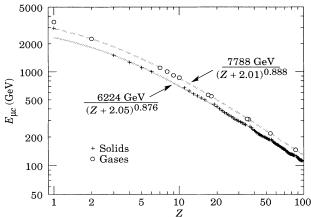

Figure 22.12: Muon critical energy for the chemical elements, defined as the energy at which radiative and ionization energy loss rates are equal. The equality comes at a higher energy for gases than for solids or liquids with the same atomic number because of a smaller density effect reduction of the ionization losses. The fits shown in the figure exclude hydrogen. Alkali metals fall 3-4% above the fitted function for alkali metals, while most other solids are within 2% of the function. Among the gases the worst fit is for neon (1.4% high). (Courtesy of N.V. Mokhov, using the MARS code system [48].)

of lost energy. Electromagnetic and hadronic cascades in detector materials can obscure muon tracks in detector planes and reduce tracking efficiency [52].

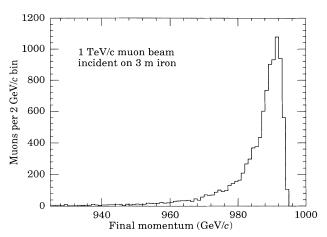

Figure 22.13: The momentum distribution of 1 TeV/c muons after traversing 3 m of iron, as obtained with Van Ginniken's TRAMU muon transport code [50].

22.10. Čerenkov and transition radiation [4,53,54]

A charged particle radiates if its velocity is greater than the local phase velocity of light (Čerenkov radiation) or if it crosses suddenly from one medium to another with different optical properties (transition radiation). Neither process is important for energy loss, but both are used in high-energy physics detectors.

<u>Čerenkov Radiation</u>. The half-angle θ_c of the Čerenkov cone for a particle with velocity βc in a medium with index of refraction n is

$$\theta_c = \arccos(1/n\beta)$$

$$\approx \sqrt{2(1-1/n\beta)} \text{ for small } \theta_c, e.g. \text{ in gases.}$$
(22.29)

The threshold velocity β_t is 1/n, and $\gamma_t = 1/(1 - \beta_t^2)^{1/2}$. Therefore, $\beta_t \gamma_t = 1/(2\delta + \delta^2)^{1/2}$, where $\delta = n - 1$. Values of δ for various

commonly used gases are given as a function of pressure and wavelength in Ref. 55. For values at atmospheric pressure, see Table 6.1. Data for other commonly used materials are given in Ref. 56.

The number of photons produced per unit path length of a particle with charge ze and per unit energy interval of the photons is

$$\frac{d^2 N}{dE dx} = \frac{\alpha z^2}{hc} \sin^2 \theta_c = \frac{\alpha^2 z^2}{r_e m_e c^2} \left(1 - \frac{1}{\beta^2 n^2(E)} \right)$$

$$\approx 370 \sin^2 \theta_c(E) \text{ eV}^{-1} \text{ cm}^{-1} \qquad (z = 1) , \qquad (22.30)$$

or, equivalently,

$$\frac{d^2N}{dxd\lambda} = \frac{2\pi\alpha z^2}{\lambda^2} \left(1 - \frac{1}{\beta^2 n^2(\lambda)}\right) \ . \tag{22.31}$$

The index of refraction is a function of photon energy E, as is the sensitivity of the transducer used to detect the light. For practical use, Eq. (22.30) must be multiplied by the the transducer response function and integrated over the region for which $\beta n(E) > 1$. Further details are given in the discussion of Čerenkov detectors in the Detectors section (Sec. 24 of this Review).

<u>Transition Radiation</u>. The energy radiated when a particle with charge ze crosses the boundary between vacuum and a medium with plasma frequency ω_p is

$$I = \alpha z^2 \gamma h \omega_p / 3 , \qquad (22.32)$$

where

$$h\omega_p = \sqrt{4\pi N_e r_e^3} \ m_e c^2/\alpha$$
$$= \sqrt{4\pi N_e a_\infty^3} \ 2 \times 13.6 \text{ eV} \ . \tag{22.33}$$

Here N_e is the electron density in the medium, r_e is the classical electron radius, and a_{∞} is the Bohr radius. For styrene and similar materials, $\sqrt{4\pi N_e a_{\infty}^3} \approx 0.8$, so that $\hbar \omega_p \approx 20$ eV. The typical emission angle is $1/\gamma$.

The radiation spectrum is logarithmically divergent at low energies and decreases rapidly for $\hbar\omega/\gamma\hbar\omega_p>1$. About half the energy is emitted in the range $0.1 \le \hbar\omega/\gamma\hbar\omega_p \le 1$. For a particle with $\gamma=10^3$, the radiated photons are in the soft x-ray range 2 to 20 eV. The γ dependence of the emitted energy thus comes from the hardening of the spectrum rather than from an increased quantum yield. For a typical radiated photon energy of $\gamma\hbar\omega_p/4$, the quantum yield is

$$N_{\gamma} \approx \frac{1}{2} \frac{\alpha z^{2} \gamma h \omega_{p}}{3} / \frac{\gamma h \omega_{p}}{4}$$
$$\approx \frac{2}{3} \alpha z^{2} \approx 0.5\% \times z^{2} . \tag{22.34}$$

More precisely, the number of photons with energy $\hbar\omega>\hbar\omega_0$ is given by [57]

$$N_{\gamma}(\hbar\omega > \hbar\omega_0) = \frac{\alpha z^2}{\pi} \left[\left(\ln \frac{\gamma \hbar\omega_p}{\hbar\omega_0} - 1 \right)^2 + \frac{\pi^2}{12} \right] , \qquad (22.35)$$

within corrections of order $(\hbar\omega_0/\gamma\hbar\omega_p)^2$. The number of photons above a fixed energy $\hbar\omega_0\ll\gamma\hbar\omega_p$ thus grows as $(\ln\gamma)^2$, but the number above a fixed fraction of $\gamma\hbar\omega_p$ (as in the example above) is constant. For example, for $\hbar\omega>\gamma\hbar\omega_p/10$, $N_\gamma=2.519\,\alpha z^2/\pi=0.59\%\times z^2$.

The yield can be increased by using a stack of plastic foils with gaps between. However, interference can be important, and the soft x rays are readily absorbed in the foils. The first problem can be overcome by choosing thicknesses and spacings large compared to the "formation length" $D = \gamma c/\omega_p$, which in practical situations is tens of μ m. Other practical problems are discussed in Sec. 24.

23. PHOTON AND ELECTRON ATTENUATION

Photon Attenuation Length

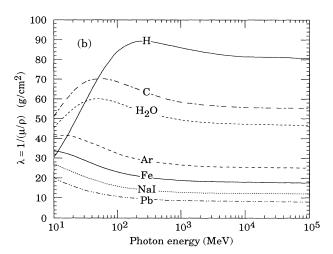

Figure 23.1: The photon mass attenuation length $\lambda = 1/(\mu/\rho)$ (also known as mfp, mean free path) for various absorbers as a function of photon energy, where μ is the mass attenuation coefficient. For a homogeneous medium of density ρ , the intensity I remaining after traversal of thickness t is given by the expression $I = I_0 \exp(-t\rho/\lambda)$. The accuracy is a few percent. Interpolation to other Z should be done in the cross section $\sigma = A/\lambda N_A \text{ cm}^2/\text{atom}$, where A is the atomic weight of the absorber material in grams and N_A is the Avogadro number. For a chemical compound or mixture, use $(1/\lambda)_{\text{eff}} \approx \sum w_i(1/\lambda)_i$, accurate to a few percent, where w_i is the proportion by weight of the i^{th} constituent. The processes responsible for attenuation are given in Fig. 23.4. Not all of these processes necessarily result in detectable attenuation. For example, coherent Rayleigh scattering off an atom may occur at such low momentum transfer that the change in energy and momentum of the photon may not be significant.

(a) Low-energy region.

(b) The photon mass attenuation length, high-energy range (note that ordinate is linear scale). The attenuation length is constant beyond the range shown for at least two decades in energy.

From Hubbell, Gimm, and Øverbø, J. Phys. Chem. Ref. Data 9, 1023 (80). See also J.H. Hubbell, Int. J. of Applied Rad. and Isotopes 33, 1269 (82). Data courtesy J.H. Hubbell.

Photon Pair Conversion Probability

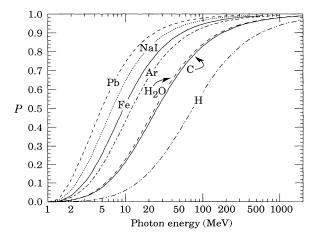

Figure 23.2: Probability P that a photon interaction will result in conversion to an e^+e^- pair. Except for a few-percent contribution from photonuclear absorption around 10 or 20 MeV, essentially all other interactions result in Compton scattering off an atomic electron. For a photon attenuation length λ (g/cm²) (Fig. 23.1), the probability that a given photon will produce an electron pair (without first Compton scattering) in thickness t (cm) of absorber of density ρ (g/cm³) is $P[1 - \exp(-t\rho/\lambda)]$.

Contributions to Photon Cross Section in Carbon and Lead

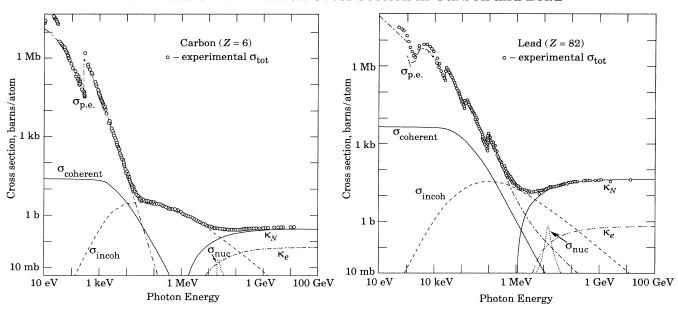

Figure 23.3: Photon total cross sections as a function of energy in carbon and lead, showing the contributions of different processes.

 $\sigma_{\rm p.e.}$ = Atomic photo-effect (electron ejection, photon absorption)

 $\sigma_{\mathrm{coherent}} = \mathrm{Coherent}$ scattering (Rayleigh scattering—atom neither ionized nor excited)

 $\sigma_{\rm incoherent} =$ Incoherent scattering (Compton scattering off an electron)

 κ_n = Pair production, nuclear field

 κ_e = Pair production, electron field

 $\sigma_{
m nuc}=$ Photonuclear absorption (nuclear absorption, usually followed by emission of a neutron or other particle)

From Hubbell, Gimm, and Øverbø, J. Phys. Chem. Ref. Data 9, 1023 (80). The photon total cross section is assumed approximately flat for at least two decades beyond the energy range shown. Figures courtesy J.H. Hubbell.

Fractional Energy Loss for Electrons and Positrons in Lead

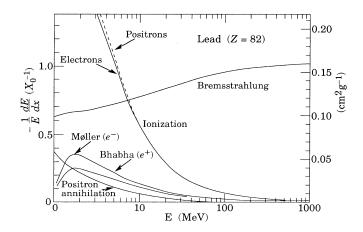

Figure 23.4: Fractional energy loss per radiation length in lead as a function of electron or positron energy. Electron (positron) scattering is considered as ionization when the energy loss per collision is below 0.255 MeV, and as Moller (Bhabha) scattering when it is above. Adapted from Fig. 3.2 from Messel and Crawford, Electron-Photon Shower Distribution Function Tables for Lead, Copper, and Air Absorbers, Pergamon Press, 1970. Messel and Crawford use $X_0(Pb) = 5.82 \text{ g/cm}^2$, but we have modified the figures to reflect the value given in the Table of Atomic and Nuclear Properties of Materials, namely $X_0(Pb)$ $= 6.4 \text{ g/cm}^2$. The development of electron-photon cascades is approximately independent of absorber when the results are expressed in terms of inverse radiation lengths (i.e., scale on left of plot).

24. PARTICLE DETECTORS

Contributed by D.G. Coyne, R.W. Fast, K. Johnson, R.D. Kephart, B. Mansoulie, H.F.W. Sadrozinski, H.G. Spieler, and C.L. Woody; revised 1995

In this section we give various parameters for common detector components. The quoted numbers are usually based on typical devices, and should be regarded only as rough approximations for new designs. A more detailed discussion of detectors can be found in Ref. 1. In Table 24.1 are given typical spatial and temporal resolutions of common detectors.

Table 24.1: Typical detector characteristics.

Detector Type	Accuracy (rms)	Resolution Time	Dead Time
Bubble chamber	10 to 150 μm	1 ms	50 ms
Streamer chamber	$300~\mu\mathrm{m}$	$2~\mu \mathrm{s}$	100 ms
Proportional chamber	$\geq 300 \ \mu \mathrm{m}^{b,c}$	50 ns	200 ns
Drift chamber	50 to 300 μm	2 ns^d	100 ns
Scintillator		150 ps	10 ns
Emulsion	$1~\mu\mathrm{m}$	_	annian and a second
Silicon strip	$\frac{\text{pitch}}{3 \text{ to } 7}^{e}$	f	f
Silicon pixel	$2~\mu\mathrm{m}^g$	f	f

- ^a Multiple pulsing time.
- ^b 300 μ m is for 1 mm pitch.
- c Delay line cathode readout can give $\pm 150~\mu\mathrm{m}$ parallel to a node wire.
- d For two chambers.
- ^e The highest resolution ("7") is obtained for small-pitch detectors ($\lesssim 25~\mu m$) with pulse-height-weighted center finding.
- f Limited at present by properties of the readout electronics. (Time resolution of ≤ 15 ns is planned for the SDC silicon tracker.)
- g Analog readout of 34 μm pitch, monolithic pixel detectors.

24.1. Organic scintillators

Organic scintillators are broadly classed into three types, crystalline, liquid, and plastic, all of which utilize the ionization produced by charged particles (see the section on "Passage of particles through matter" (Sec. 22.2) of this Review) to generate optical photons, usually in the blue to green wavelength regions [2]. Plastic scintillators are by far the most widely used and we address them primarily; however, most of the discussion will also have validity for liquid scintillators with obvious caveats. Crystal organic scintillators are practically unused in high-energy physics.

Densities range from 1.03 to 1.20 g cm⁻³. Typical photon yields are about 1 photon per 100 eV of energy deposit [3]. A one-cm-thick scintillator traversed by a minimum-ionizing particle will therefore yield $\approx 2\times 10^4$ photons. The resulting photoelectron signal will depend on the collection and transport efficiency of the optical package and the quantum efficiency of the photodetector.

Plastic scintillators do not respond linearly to the ionization density. Very dense ionization columns emit less light than expected on the basis of dE/dx for minimum-ionizing particles. A widely used semi-empirical model by Birks posits that recombination and quenching effects between the excited molecules reduce the light yield [9]. These effects are more pronounced the greater the density of the excited molecules. Birks' formula is

$$\frac{d\mathcal{L}}{dx} = \mathcal{L}_0 \frac{dE/dx}{1 + k_B dE/dx} , \qquad (24.1)$$

where \mathscr{L} is the luminescence, \mathscr{L}_0 is the luminescence at low specific ionization density, and k_B is Birks' constant, which must be determined for each scintillator by measurement.

Decay times are in the ns range; risetimes are much faster. The combination of high light yield and fast response time allows the possibility of sub-ns timing resolution [4]. The fraction of light emitted during the decay "tail" can depend on the exciting particle. This allows pulse shape discrimination as a technique to carry out particle identification. Because of the hydrogen content (carbon to hydrogen ratio ≈ 1) plastic scintillator is sensitive to proton recoils from neutrons. Ease of fabrication into desired shapes and low cost has made plastic scintillators a common detector component. Recently, plastic scintillators in the form of scintillating fibers have found widespread use in tracking and calorimetry [5].

24.1.1. Scintillation mechanism:

Scintillation: A charged particle traversing matter leaves behind it a wake of excited molecules. Certain types of molecules, however, will release a small fraction ($\approx 3\%$) of this energy as optical photons. This process, scintillation, is especially marked in those organic substances which contain aromatic rings, such as polystyrene, polyvinyltoluene, and napthalene. Liquids which scintillate include toluene and xylene.

Fluorescence: In fluorescence, the initial excitation takes place via the absorption of a photon, and de-excitation by emission of a longer wavelength photon. Fluors are used as "waveshifters" to shift scintillation light to a more convenient wavelength. Occurring in complex molecules, the absorption and emission are spread out over a wide band of photon energies, and have some overlap, that is, there is some fraction of the emitted light which can be re-absorbed [6]. This "self-absorption" is undesirable for detector applications because it causes a shortened attenuation length. The wavelength difference between the major absorption and emission peaks is called the Stokes' shift. It is usually the case that the greater the Stokes' shift, the smaller the self absorption—thus, a large Stokes' shift is a desirable property for a fluor.

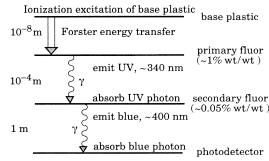

Figure 24.1: Cartoon of scintillation "ladder" depicting the operating mechanism of plastic scintillator. Approximate fluor concentrations and energy transfer distances for the separate sub-processes are shown.

Scintillators: The plastic scintillators used in high-energy physics are binary or ternary solutions of selected fluors in a plastic base containing aromatic rings. (See the appendix in Ref. 7 for a comprehensive list of plastic scintillator components.) Virtually all plastic scintillators contain as a base either polyvinyltoluene, polystyrene, or acrylic, whereby polyvinyltoluene-based scintillator can be up to 50% brighter than the others. Acrylic is non-aromatic and has therefore a very low scintillation efficiency. It becomes an acceptable scintillator when napthalene, a highly aromatic compound, is dissolved into the acrylic at 5% to 20% weight fraction. Thus, in "acrylic" scintillator the active component is napthalene. The fluors must satisfy additional conditions besides being fluorescent. They must be sufficiently stable, soluble, chemically inert, fast, radiation tolerant, and efficient.

The plastic base is the ionization-sensitive (i.e., the scintillator) portion of the plastic scintillator (see Fig. 24.1). In the absence of fluors the base would emit UV photons with short attenuation length (several mm). Longer attenuation lengths are obtained by dissolving a "primary" fluor in high concentration (1% by weight) into the

base, which is selected to efficiently reradiate absorbed energy at wavelengths where the base is more transparent.

The primary fluor has a second important function. The decay time of the scintillator base material can be quite long—in pure polystyrene it is 16 ns, for example. The addition of the primary fluor in high concentration can shorten the decay time by an order of magnitude and increase the total light yield. At the concentrations used (1% and greater), the average distance between a fluor molecule and an excited base unit is around 100 Å, much less than a wavelength of light. At these distances the predominant mode of energy transfer from base to fluor is not the radiation of a photon, but a resonant dipole-dipole interaction, first described by Foerster, which strongly couples the base and fluor [8]. The strong coupling sharply increases the speed and the light yield of the plastic scintillators.

Unfortunately, a fluor which fulfills other requirements is usually not completely adequate with respect to emission wavelength or attenuation length, so it is necessary to add yet another waveshifter (the "secondary" fluor), at fractional percent levels, and ocassionally a third (not shown in Fig. 24.1).

External wavelength shifters: Light emitted from a plastic scintillator may be absorbed in a (nonscintillating) base doped with a waveshifting fluor. Such wavelength shifters are widely used to aid light collection in complex geometries. The wavelength shifter must be insensitive to ionizing radiation and Čerenkov light. A typical wavelength shifter uses an acrylic base (without napthalene!) because of its good optical qualities, a single fluor to shift the light emerging from the plastic scintillator to the blue-green, and contains ultra-violet absorbing additives to deaden response to Čerenkov light.

24.1.2. Caveats and cautions: Plastic scintillators are reliable, robust, and convenient. However, they possess quirks to which the experimenter must be alert.

Aging and Handling: Plastic scintillators are subject to aging which diminishes the light yield. Exposure to solvent vapors, high temperatures, mechanical flexing, irradiation, or rough handling will aggravate the process. A particularly fragile region is the surface which can "craze"—develop microcracks—which rapidly destroy the capability of plastic scintillators to transmit light by total internal reflection. Crazing is particularly likely where oils, solvents, or fingerprints have contacted the surface.

Attenuation length: The Stokes' shift is not the only factor determining attenuation length. Others are the concentration of fluors (the higher the concentration of a fluor, the greater will be its self-absorption); the optical clarity and uniformity of the bulk material; the quality of the surface; and absorption by additives, such as stabilizers, which may be present.

<u>Afterglow</u>: Plastic scintillators have a long-lived luminescence which does not follow a simple exponential decay. Intensities at the 10^{-4} level of the initial fluorescence can persist for hundreds of ns [10].

Atmospheric quenching: Plastic scintillators will decrease their light yield with increasing partial pressure of oxygen. This can be a 10% effect in an artificial atmosphere [11]. It is not excluded that other gasses may have similar quenching effects.

<u>Magnetic field</u>: The light yield of plastic scintillators may be changed by a magnetic field. The effect is very nonlinear and apparently not all types of plastic scintillators are so affected. Increases of $\approx 3\%$ at 0.45 T have been reported [12]. Data are sketchy and mechanisms are not understood.

Radiation damage: Irradiation of plastic scintillators creates color centers which absorb light more strongly in the UV and blue than at longer wavelengths. This poorly understood effect appears as a reduction both of light yield and attenuation length. Radiation damage depends not only on the integrated dose, but on the dose rate, atmosphere, and temperature, before, during and after irradiation, as well as the materials properties of the base such as glass transition temperature, polymer chain length, etc. Annealing also occurs,

accelerated by the diffusion of atmospheric oxygen and elevated temperatures. The phenomena are complex, unpredictable, and not well understood [13]. Since color centers are less intrusive at longer wavelengths, the most reliable method of mitigating radiation damage is to shift emissions at every step to the longest practical wavelengths, e.g., utilize fluors with large Stokes' shifts.

24.2. Inorganic scintillators

Table 24.2 gives a partial list of commonly-used inorganic scintillators in high-energy and nuclear physics [14-21]. These scintillating crystals are generally used where high density and good energy resolution are required. In a crystal which contains nearly all of the energy deposited by an incident particle, the energy resolution is determined largely, but not totally, by the light output. The table gives the light output of the various materials relative to NaI, which has an intrinsic light output of about 40000 photons per MeV of energy deposit. The detected signal is usually quoted in terms of photoelectrons per MeV produced by a given photodetector. The relationship between photons/MeV produced and p.e.'s/MeV detected involves factors for light collection efficiency (typically 10-50%, depending on geometry) and the quantum efficiency of the detector ($\sim 15-20\%$ for photomultiplier tubes and $\sim 70\%$ for silicon photodiodes for visible wavelengths). The quantum efficiency of the detector is usually highly wavelength dependent and should be matched to the particular crystal of interest to give the highest quantum yield at the wavelength corresponding to the peak of the scintillation emission. The comparison of the light output given in Table 24.2 is for a standard photomultiplier tube with a bialkali photocathode. For scintillators which emit in the UV, a detector with a quartz window should be used.

24.3. Čerenkov detectors

Čerenkov detectors utilize one or more of the properties of Čerenkov radiation discussed in the Passages of Particles through Matter section (Sec. 22 of this Review): the existence of a threshold for radiation; the dependence of the Čerenkov cone half-angle θ_c on the velocity of the particle; the dependence of the number of emitted photons on the particle's velocity. The presence of the refractive index n in the relations allows tuning these quantities for a particular experimental application (e.g., using pressurized gas and/or various liquids as radiators).

The number of photoelectrons (p.e.'s) detected in a given device or channel is

$$N_{\rm p.c.} = L \frac{\alpha^2 z^2}{r_e \, m_e c^2} \int \epsilon_{\rm coll}(E) \, \epsilon_{\rm det}(E) \sin^2 \theta_c(E) dE$$
, (24.2)

where L is the path length in the radiator, $\epsilon_{\rm coll}$ is the efficiency for collecting the Čerenkov light, $\epsilon_{\rm dct}$ is the quantum efficiency of the transducer (photomultiplier or equivalent), and $\alpha^2/(r_e\,m_ec^2)=370~{\rm cm}^{-1}{\rm eV}^{-1}$. The quantities $\epsilon_{\rm coll}$, $\epsilon_{\rm dct}$, and θ_c are all functions of the photon energy E, although in typical detectors θ_c (or, equivalently, the index of refraction) is nearly constant over the useful range of photocathode sensitivity. In this case,

$$N_{\rm p.e.} \approx L N_0 \left\langle \sin^2 \theta_c \right\rangle$$
 (24.3)

with

$$N_0 = \frac{\alpha^2 z^2}{r_e \, m_e c^2} \, \int \epsilon_{\text{coll}} \, \epsilon_{\text{dct}} dE \ . \tag{24.4}$$

We take z = 1, the usual case in high-energy physics, in the following discussion.

Threshold Čerenkov detectors make a simple yes/no decision based on whether the particle is above/below the Čerenkov threshold velocity $\beta_t=1/n.$ Careful designs give $\langle\epsilon_{\rm coll}\rangle\gtrsim90\%.$ For a photomultiplier with a typical bialkali cathode, $\int\epsilon_{\rm det}dE\approx0.27,$ so that

$$N_{\rm p.c.}/L \approx 90~{\rm cm}^{-1}~\left<\sin^2\theta_c\right>~(i.e.,~N_0=90~{\rm cm}^{-1})~.~(24.5)$$

Suppose, for example, that n is chosen so that the threshold for species a is p_t ; that is, at this momentum species a has velocity $\beta_a = 1/n$. A second, lighter, species b with the same momentum has velocity β_b , so $\cos \theta_c = \beta_a/\beta_b$, and

$$\frac{N_{\text{p.e.}}}{L} \approx 90 \text{ cm}^{-1} \frac{m_a^2 - m_b^2}{p_t^2 + m_a^2}$$
 (24.6)

For K/π separation at p=1 GeV/c, $N_{\rm p.c.}/L\approx 16$ cm⁻¹ for π 's and (by design) 0 for K's.

For limited path lengths $N_{\rm p.c.}$ can be small, and some minimum number is required to trigger external electronics. The overall efficiency of the device is controlled by Poisson fluctuations, which can be especially critical for separation of species where one particle type is dominant [22].

A related class of detectors uses the number of observed photoelectrons (or the calibrated pulse height) to discriminate between species or to set probabilities for each particle species [23].

<u>Differential Čerenkov detectors</u> exploit the dependence of θ_c on β , using optical focusing and/or geometrical masking to select particles having velocities in a specified region. With careful design, a velocity resolution of $\sigma_{\beta}/\beta \approx 10^{-4}$ - 10^{-5} can be obtained [22,24].

Ring-Imaging Čerenkov detectors use all three properties of Čerenkov radiation in both small-aperture and 4π geometries. They are principally used as hypothesis-testing rather than yes/no devices; that is, the probability of various identification possibilities is established from θ_c and $N_{\rm p.c.}$ for a particle of known momentum. In most cases

Table 24.3: Momentum range for 3σ separation in the SLD ring-imaging Čerenkov detector.

Particle pair	Mom. range for 3 σ separation
e/π	$p \lesssim 5 \text{GeV}/c$
π/K	$0.23 \lesssim p \lesssim 20 \mathrm{GeV}/c$
K/p	$0.82 \lesssim p \lesssim 30 \mathrm{GeV}/c$

the optics map the Čerenkov cone onto a circle at the photodetector, often with distortions which must be understood.

The 4π devices [25,26] typically have both liquid (C₆F₁₄, n=1.276) and gas (C₅F₁₂, n=1.0017) radiators, the light from the latter being focused by mirrors. They achieve 3 σ separation of $e/\pi/K/p$ over wide ranges, as shown in Table 24.3. Great attention to detail, especially with the minimization of UV-absorbing impurities, is required to get $\langle \epsilon_{\rm coll} \rangle \gtrsim 50\%$.

The phototransducer is typically a TPC/wire-chamber combination sensitive to single photoelectrons and having charge division or pads. This construction permits three-dimensional reconstruction of photoelectron origins, which is important for transforming the Čerenkov cone into a ring. Single photoelectrons are generated by doping the TPC gas (for instance, ethane/methane in some proportion) with $\sim 0.05\%$ TMAE [tetrakis(dimethylamino)ethylene] [27], leading to photon absorption lengths along the Čerenkov cone of ~ 30 mm. The readout wires must be equipped with special structures (blinds or wire gates) to prevent photon feedback from avalanches generating cross-talk photoelectrons in the TPC. Drift-gas purity must be maintained to assure mean drift lengths of the order of meters without recombination (i.e., lifetimes of $\gtrsim 100~\mu s$ at typical drift velocities of $\gtrsim 4~\rm cm/\mu s$). The net $\langle \epsilon_{\rm det} \rangle$'s reach 30%, with the limitation being the TMAE quantum efficiency.

Photon energy cutoffs are set by the TMAE $(E>5.4~{\rm eV})$, the UV transparency of fused silica glass $(E<7.4~{\rm eV})$, and the ${\rm C_6F_{14}}$ $(E<7.1~{\rm eV})$. With effort one gets $50\leq N_0\leq 100$ for complete rings using liquid or gas. This includes losses due to electrostatic shielding wires and window/mirror reflections, but not gross losses caused by total internal reflection or inadequate coverage by the TPC's.

Such numbers allow determination of ring radii to $\sim 0.5\%$ (liquid) and $\sim 2\%$ (gas), leading to the particle species separations quoted above. Since the separation efficiencies may have "holes" as a function of p, detailed calculations are necessary.

24.4. Transition radiation detectors (TRD's)

It is clear from the discussion in the Passages of Particles Through Matter section (Sec. 22 of this Review) that transition radiation (TR) only becomes useful for particle detectors when the Lorentz factor $\gamma \gtrsim 10^3$. In practice, TRD's are used to provide e/π separation when $p\gtrsim 1$ GeV/c. (The momentum is usually measured elsewhere in the detector.) Since a soft x ray is radiated with about 1% probability per boundary crossing, practical detectors use radiators with several hundred interfaces, e.g. foils of lithium or plastic in a gas. Absorption inside the radiator and interference effects between interfaces are important [28,29].

A practical detector is composed of several similar modules, each consisting of a radiator and an x-ray detector. The radiator is made of foils or fibers of a low-Z material (for low absorption) in a low-Z gas such as helium. The x-ray detector is usually a wire chamber operated with a xenon-rich mixture in order to obtain a high conversion efficiency. As transition radiation is emitted at small angles, the chamber usually detects the sum of the ionization of the particle and of converted TR photons. The discrimination between electrons and pions can be based on the charges measured in each set, or on more sophisticated methods using pulse-shape analysis.

The major factor in the performance of a TRD is its overall length. Very roughly, the pion rejection factor for a detector with 90% electron efficiency is $10\,(L/20\,$ cm), where L is the overall length of the detector.

Recent development work has aimed at adapting the technique to the very high particle rate at LHC, by distributing straw-tube detectors uniformly in the radiator foam, and using very fast electronics. The resulting detector is used as a tracking device as well as a TRD [30].

24.5. Silicon photodiodes and particle detectors

Silicon detectors are p-n junction diodes operated at reverse bias. This forms a sensitive region depleted of mobile charge and sets up an electric field that sweeps charge liberated by radiation to the electrodes. The thickness of the depleted region is

$$W = \sqrt{\frac{2\epsilon \left(V + V_{bi}\right)}{ne}} = \sqrt{2\rho\mu\epsilon(V + V_{bi})} , \qquad (24.7)$$

where V = external bias voltage

 $V_{bi}=$ "built-in" voltage ($\approx 0.8~\mathrm{V}$ for resistivities typically used in detectors

n =doping concentration

e = electron charge

 $\epsilon = \text{dielectric constant} = 11.9 \ \epsilon_0 \approx 1 \ \text{pF/cm}$

 $\rho = \text{resistivity (typically 1-10 k}\Omega \text{ cm)}$

 $\mu = \text{charge carrier mobility}$

= $1350 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ for electrons (*n*-type material)

= $450 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ for holes (p-type material)

or

$$W = 0.5 \ \mu \text{m} \times \sqrt{\rho(V + V_{bi})}$$
 for *n*-type material, (24.8)

and

$$W = 0.3 \ \mu \text{m} \times \sqrt{\rho (V + V_{bi})}$$
 for p-type material, (24.9)

where V is in volts and ρ is in Ω cm.

The corresponding capacitance per unit area is

$$C = \frac{\epsilon}{W} \approx 1 \,[\text{pF/cm}] \,\frac{1}{W} \,. \tag{24.10}$$

In strip detectors the capacitance is dominated by the strip-to-strip fringing capacitance of $\sim 1\text{--}1.5$ pF cm⁻¹ of strip length at a strip pitch of 25–50 μ m.

About 3.6 eV is required to create an electron-hole pair. For minimum-ionizing particles, the most probable charge deposition in a 300 μ m thick silicon detector is about 4 fC (25000 electrons). Readily available photodiodes have quantum efficiences > 70% for wavelengths between 600 nm and 1 μ m. UV extended photodiodes have useful efficiency down to 200 nm. In applications in which photodiodes detect light from scintillators, care must be taken so that signal from the scintillator is larger than that produced by particles going through the photodiode

Collection time decreases with increased depletion voltage, and can be reduced further by operating the detector with "overbias," *i.e.*, a bias voltage exceeding the value required to fully deplete the device. The collection time is limited by velocity saturation at high fields; at an average field of 10^4 V/cm, the collection times is about 15 ps/ μ m for electrons and 30 ps/ μ m for holes. In typical strip detectors of 300 μ m thickness, electrons are collected within about 8 ns, and holes within about 25 ns.

Position resolution is limited by transverse diffusion during charge collection (typically 5 μ m for 300 μ m thickness) and by knock-on electrons. Resolutions of 3–4 μ m (rms) have been obtained in beam tests. In magnetic fields, the Lorentz drift can increase the spatial spread appreciably (see "Hall effect" in semiconductor textbooks).

Radiation damage occurs through two basic mechanisms:

- Bulk damage due to displacement of atoms from their lattice sites.
 This leads to increased leakage current, carrier trapping, and changes in doping concentration. Displacement damage depends on the nonionizing energy loss, i.e., particle type and energy. The dose should be specified as a fluence of particles of a specific type and energy.
- 2. Surface damage due to charge build-up in surface layers, which leads to increased surface leakage currents. In strip detectors the inter-strip isolation is affected. The effects of charge build-up are strongly dependent on the device structure and on fabrication details. Since the damage is determined directly by the absorbed energy, the dose should be specified in these units (rad or Gray).

The increase in leakage current due to bulk damage is $\Delta i = \alpha \phi$ per unit volume, where ϕ is the particle fluence and α the damage coefficient ($\alpha \approx 2 \times 10^{-17}$ A/cm for minimum ionizing protons and pions after long-term annealing; roughly the same value applies for 1 MeV neutrons). The doping concentration in n-type silicon changes as $n = n_0 \exp(-\delta \phi) - \beta \phi$, where n_0 is the initial donor concentration, $\delta \approx 6 \times 10^{14}$ cm² determines donor removal, and $\beta \approx 0.03$ cm⁻¹ describes acceptor creation. This leads to an initial increase in resisitivity until type-inversion changes the net doping from n to p. At this point the resistivity decreases, with a corresponding increase in depletion voltage. The safe operating limit of depletion voltage ultimately limits the detector lifetime. Strip detectors have remained functional at fluences beyond 10^{14} cm⁻² for minimum ionizing protons. At this damage level, charge loss due to recombination and trapping also seems to become significant.

24.6. Proportional and drift chambers

<u>Proportional chamber wire instability</u>: The limit on the voltage V for a wire tension T, due to mechanical effects when the electrostatic repulsion of adjacent wires exceeds the restoring force of wire tension, is given by (SI units) [31]

$$V \le \frac{s}{\ell C} \sqrt{4\pi\epsilon_0 T} , \qquad (24.11)$$

where s, ℓ , and C are the wire spacing, length, and capacitance per unit length. An approximation to C for chamber half-gap t and wire diameter d (good for $s \lesssim t$) gives [32]

$$V \lesssim 59T^{1/2} \left[\frac{t}{\ell} + \frac{s}{\pi \ell} \ln \left(\frac{s}{\pi d} \right) \right] ,$$
 (24.12)

where V is in kV, and T is in grams-weight equivalent.

<u>Proportional and drift chamber potentials</u>: The potential distributions and fields in a proportional or drift chamber can usually be calculated with good accuracy from the exact formula for the potential around an array of parallel line charges q (coul/m) along z and located at $y=0,\,x=0,\,\pm s,\,\pm 2s,\,\ldots$,

$$V(x,y) = -\frac{q}{4\pi \epsilon_0} \ln \left\{ 4 \left[\sin^2 \left(\frac{\pi x}{s} \right) + \sinh^2 \left(\frac{\pi y}{s} \right) \right] \right\} . \tag{24.13}$$

Errors from the presence of cathodes, mechanical defects, TPC-type edge effects, etc., are usually small and are beyond the scope of this review

24.7. Calorimeters

Electromagnetic calorimeters: The development of electromagnetic showers is discussed in the "Passage of Particles Through Matter" section (Sec. 22 of this *Review*). Formulae are given for the approximate description of average showers, but since the physics of electromagnetic showers is well understood, detailed and reliable Monte Carlo simulation is possible. EGS4 has emerged as the standard [33].

The resolution of sampling calorimeters (hadronic and electromagnetic) is usually dominated by sampling fluctuations, leading to fractional resolution σ/E scaling inversely as the square root of the incident energy. Homogenous calorimeters, such as solid NaI(Tl), will

in general not have resolution varying as $1/\sqrt{E}$. At high energies deviations from $1/\sqrt{E}$ occur because of noise, pedestal fluctuations, nonuniformities, calibration errors, and incomplete shower containment. Such effects are usually included by adding a constant term to σ/E , either in quadrature or (incorrectly) directly. In the case of the hadronic cascades discussed below, noncompensation also contributes to the constant term.

In Table 24.4 we give resolution as measured in detectors using typical EM calorimeter technologies. In almost all cases the installed calorimeters yield worse resolution than test beam prototypes for a variety of practical reasons. Where possible actual detector performance is given. For a fixed number of radiation lengths, the FWHM in sandwich detectors would be expected to be proportional to \sqrt{t} for t (= plate thickness) \geq 0.2 radiation lengths [34].

Given sufficient transverse granularity early in the calorimeter, position resolution of the order of a millimeter can be obtained.

Table 24.4: Resolution of typical electromagnetic calorimeters. E is in GeV.

Detector	Resolution
$NaI(Tl)$ (Crystal Ball [35]; 20 X_0)	$2.7\%/E^{1/4}$
Lead glass (OPAL [36])	$5\%/\sqrt{E}$
Lead-liquid argon (NA31 [37]; 80 cells: 27 X_0 , 1.5 mm Pb + 0.6 mm Al + 0.8 mm G10 + 4 mm LA)	$7.5\%/\sqrt{E}$
Lead-scintillator sandwich (ARGUS [38], LAPP-LAL [39])	$9\%/\sqrt{E}$
Lead-scintillator spaghetti (CERN test module) [40]	$13\%/\sqrt{E}$
Proportional wire chamber (MAC; 32 cells: 13 X_0 , 2.5 mm typemetal + 1.6 mm Al) [41]	$23\%/\sqrt{E}$

<u>Hadronic calorimeters</u> [42,43]: The length scale appropriate for hadronic cascades is the nuclear interaction length, given very roughly by

$$\lambda_I \approx 35 \text{ g cm}^{-2} A^{1/3}$$
 (24.14)

Longitudinal energy deposition profiles are characterized by a sharp peak near the first interaction point (from the fairly local deposition of EM energy resulting from π^0 's produced in the first interaction), followed by a more gradual development with a maximum at

$$x/\lambda_I \equiv t_{\text{max}} \approx 0.2 \ln(E/1 \text{ GeV}) + 0.7 \tag{24.15}$$

as measured from the front of the detector.

The depth required for containment of a fixed fraction of the energy also increases logarithmically with incident particle energy. The thickness of iron required for 95% (99%) containment of cascades induced by single hadrons is shown in Fig. 24.2 [44]. Two of the sets of data are from large neutrino experiments, while the third is from a commonly used parametrization. Depths as measured in nuclear interaction lengths presumably scale to other materials. From the same data it can be concluded that the requirement that 95% of the energy in 95% of the showers be contained requires 40 to 50 cm (2.4 to $3.0 \ \lambda_I$) more material material than for an average 95% containment.

The transverse dimensions of hadronic showers also scale as λ_I , although most of the energy is contained in a narrow core.

The energy deposit in a hadronic cascade consists of a prompt EM component due to π^0 production and a slower component mainly due to low-energy hadronic activity. In general, these energy depositions are converted to electrical signals with different efficiencies [45]. The ratio of the conversion efficiencies is usually called the intrinsic e/h ratio. If e/h=1.0 the calorimeter is said to be compensating. If it differs from unity by more than 5% or 10%, detector performance is compromised because of fluctuations in the π^0 content of the cascades. Problems include:

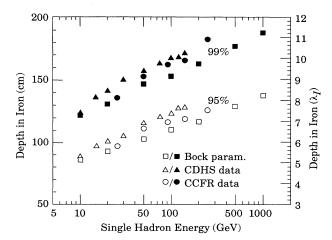

Figure 24.2: Required calorimeter thickness for 95% and 99% hadronic cascade containment in iron, on the basis of data from two large neutrino detectors and the parametrization of Bock et al. [44].

- a) A skewed signal distribution;
- b) A response ratio for electrons and hadrons (the " e/π ratio") which is different from unity and depends upon energy;
- c) A nonlinear response to hadrons (the response per GeV is proportional to the reciprocal of e/π);
- d) A constant contribution to detector resolution, almost proportional to the degree of noncompensation. The coefficient relating the constant term to |1-e/h| is 14% according to FLUKA simulations, and 21% according to Wigman's calculations [42].

In most cases e/h is greater than unity, particularly if little hydrogen is present or if the gate time is short. This is because much of the low-energy hadronic energy is "hidden" in nuclear binding energy release, low-energy spallation products, etc. Partial correction for these losses occurs in a sampling calorimeter with thick plates, because a disproportionate fraction of electromagnetic energy is deposited in the inactive region. For this reason, a fully sensitive detector such as BGO or glass cannot be made compensating.

Compensation has been demonstrated in calorimeters with 2.5 mm scintillator sheets sandwiched between 3 mm depleted uranium plates [47] or 10 mm lead plates [48]; resolutions σ/E of $0.34/\sqrt{E}$ and $0.44/\sqrt{E}$ were obtained for these cases (E in GeV). The former was shown to be linear to within 2% over three orders of magnitude in energy, with approximately Gaussian signal distributions.

24.8. Measurement of particle momenta in a uniform magnetic field [54]

The trajectory of a particle with momentum p (in GeV/c) and charge ze in a constant magnetic field \overrightarrow{B} is a helix, with radius of curvature R and pitch angle λ . The radius of curvature and momentum component perpendicular to \overrightarrow{B} are related by

$$p\cos\lambda = 0.3 z B R$$
, (24.16)

where B is in tesla and R is in meters.

The distribution of measurements of the curvature $k\equiv 1/R$ is approximately Gaussian. The curvature error for a large number of uniformly spaced measurements on the trajectory of a charged particle in a uniform magnetic field can be approximated by

$$(\delta k)^2 = (\delta k_{\rm res})^2 + (\delta k_{\rm ms})^2$$
, (24.17)

where $\delta k = \text{curvature error}$

 $\delta k_{
m res} = {
m curvature~error}$ due to finite measurement resolution $\delta k_{
m ms} = {
m curvature~error}$ due to multiple scattering.

If many (≥ 10) uniformly spaced position measurements are made along a trajectory in a uniform medium,

$$\delta k_{\rm res} = \frac{\epsilon}{L^2} \sqrt{\frac{720}{N+4}} \,, \tag{24.18}$$

where N = number of points measured along track

L'= the projected length of the track onto the bending plane $\epsilon=$ measurement error for each point, perpendicular to the

If a vertex constraint is applied at the origin of the track, the coefficient under the radical becomes 320.

The contribution due to multiple Coulomb scattering is approximately

$$\delta k_{\rm ms} \approx \frac{(0.016)({\rm GeV}/c)z}{Lp\beta\cos^2\lambda}\sqrt{\frac{L}{X_0}} \;,$$
 (24.19)

where $p={
m momentum}~({
m GeV}/c)$

trajectory.

z = charge of incident particle in units of e

L = the total track length

 X_0 = radiation length of the scattering medium (in units of length; the X_0 defined elsewhere must be multiplied by density)

 $\beta =$ the kinematic variable v/c.

More accurate approximations for multiple scattering may be found in the section on Passage of Particles Through Matter (Sec. 22 of this Review). The contribution to the curvature error is given approximately by $\delta k_{\rm ms} \approx 8 s_{\rm plane}^{\rm rms}/L^2$, where $s_{\rm plane}^{\rm rms}$ is defined there.

24.9. Superconducting solenoids for collider detectors

24.9.1. Basic (approximate) equations: In all cases SI units are assumed, so that B is in tesla, E is in joules, dimensions are in meters, and $\mu_0 = 4\pi \times 10^{-7}$.

<u>Magnetic field</u>: The magnetic field at the center of a solenoid of length L and radius R, having N total turns and a current I is

$$B(0,0) = \frac{\mu_0 NI}{\sqrt{L^2 + 4R^2}} \ . \tag{24.20}$$

Stored energy: The energy stored in the magnetic field of any magnet is calculated by integrating B^2 over all space:

$$E = \frac{1}{2\mu_0} \int B^2 dV \ . \tag{24.21}$$

For a solenoid with an iron flux return in which the magnetic field is < 2T, the field in the aperture is approximately uniform and equal to $\mu_0 NI/L$. If the thickness of the coil is small, (which is the case if it is superconducting), then

$$E \approx (\pi/2\mu_0)B^2R^2L$$
 (24.22)

Cost of a superconducting solenoid [55]:

Cost (in M\$) =
$$0.523 [(E/(1 \text{ MJ})]^{0.662}$$
 (24.23)

<u>Magnetostatic computer programs</u>: It is too difficult to solve the Biot-Savart equation for a magnetic circuit which includes iron components and so iterative computer programs are used. These include POISSON, TOSCA [56], and ANSYS [57].

24.9.2. Scaling laws for thin solenoids: For a detector in which the calorimetry is outside the aperture of the solenoid, the coil must be thin in terms of radiation and absorption lengths. This usually means that the coil is superconducting and that the vacuum vessel encasing it is of minimum real thickness and fabricated of a material with long radiation length. There are two major contributers to the thickness of a thin solenoid:

- 1. The conductor, consisting of the current-carrying superconducting material (usually Cu/Nb-Ti) and the quench protecting stabilizer (usually aluminum), is wound on the inside of a structural support cylinder (usually aluminum also). This package typically represents about 60% of the total thickness in radiation lengths. The thickness scales approximately as B^2R .
- 2. Approximately another 25% of the thickness of the magnet comes from the outer cylindrical shell of the vacuum vessel. Since this shell is susceptible to buckling collapse, its thickness is determined by the diameter, length, and the modulus of the material of which it is fabricated. When designing this shell to a typical standard, the real thickness is

$$t = P_c D^{2.5} [(L/D) - 0.45(t/D)^{0.5}] / 2.6Y^{0.4}, \qquad (24.24)$$

where t = shell thickness (in), D = shell diameter (in), L = shell length (in), Y = modulus of elasticity (psi), and $P_c =$ design collapse pressure (= 30 psi). For most large-diameter detector solenoids, the thickness to within a few percent is given by [58]

$$t = P_c D^{2.5} (L/D) / 2.6 Y^{0.4} (24.25)$$

24.9.3. Properties of collider detector solenoids: The physical dimensions, central field, stored energy and thickness in radiation lengths normal to the beam line of the superconducting solenoids associated with the major colliders are given in Table 24.5.

Table 24.5: Properties of superconducting collider detector solenoids.

Experiment-Lab	Field (T)	Bore Dia (m)	Length (m)	Energy (MJ)	Thickness (X_0)
CDF-Fermilab	1.5	2.86	5.07	30	0.86
Topaz-KEK	1.2	2.72	5.4	19.5	0.70
Venus-KEK	0.75	3.4	5.64	12	0.52
Cleo II-Cornell	1.5	2.9	3.8	25	2.5
Aleph-CERN	1.5	5.0	7.0	130	1.7
Delphi-CERN	1.2	5.2	7.4	109	4.0
H1-DESY	1.2	5.2	5.75	120	1.2
Zeus-DESY	1.8	1.72	2.85	10.5	0.9

The ratio of stored energy to cold mass (E/M) is a useful performance measure. One would like the cold mass to be as small as possible to minimize the thickness, but temperature rise during a quench must also be minimized. Ratios as large as 8 kJ/kg may be possible (final temperature of 80 K after a fast quench with homogenous energy dump), but some contingency is desirable. This quantity is shown as a function of total stored energy for some major collider detectors in Fig. 24.3.

24.10. Other observations

 $\underline{dE/dx}$ resolution in argon: Particle identification by dE/dx is dependent on the width of the distribution. For relativistic incident particles with charge e in a multiple-sample Ar gas counter with no lead [49],

$$\frac{dE}{dx}\Big|_{\text{FWHM}} / \frac{dE}{dx}\Big|_{\text{most probable}} = 0.96 \, N^{-0.46} \, (xp)^{-0.32} \, , \quad (24.26)$$

where N= number of samples, x= thickness per sample (cm), p= pressure (atm.). Most commonly used chamber gases (except Xe) give approximately the same resolution.

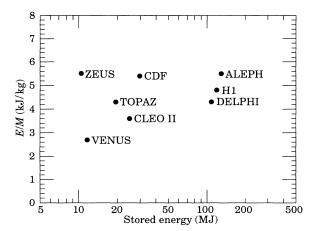

Figure 24.3: Ratio of stored energy to cold mass for existing thin detector solenoids.

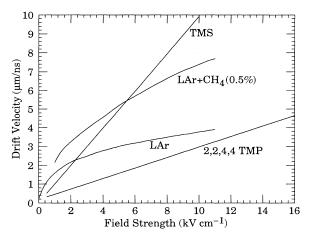

Figure 24.4: Electron drift velocity as a function of field strength for commonly used liquids.

<u>Free electron drift velocities in liquid ionization chambers</u> [50–53]: Velocity as a function of electric field strength is given in Fig. 24.4.

25. RADIOACTIVITY & RADIATION PROTECTION

Revised Sept. 1995 by R.J. Donahue (LBNL) and A. Fasso (CERN).

25.1. Definitions

The International Commission on Radiation Units and Measurements (ICRU) recommends the use of SI units. Therefore we list SI units first, followed by cgs (or other common) units in parentheses, where they differ.

- Unit of activity = becquerel (curie):
 - 1 Bq = 1 disintegration $s^{-1} = 1/(3.7 \times 10^{10})$ Ci
- Unit of absorbed dose = gray (rad):
 - 1 Gy = 1 joule kg^{-1} (= 10^4 erg g^{-1} = 100 rad) = 6.24×10^{12} MeV kg^{-1} deposited energy
- Unit of exposure, the quantity of x- or γ radiation at a point in space integrated over time, in terms of charge of either sign produced by showering electrons in a small volume of air about the point:
 - = 1 coul kg⁻¹ of air (roentgen; 1 $R = 2.58 \times 10^{-4}$ coul kg⁻¹)
 - $= 1 \text{ esu cm}^{-3} (= 87.8 \text{ erg released energy per g of air})$

Implicit in the definition is the assumption that the small test volume is embedded in a sufficiently large uniformly irradiated volume that the number of secondary electrons entering the volume equals the number leaving. This unit is somewhat historical, but appears on many measuring instruments.

• Unit of equivalent dose (for biological damage) = sievert [= 100 rem (roentgen equivalent for man)]: Equivalent dose in Sv = absorbed dose in grays \times w_R , where w_R (radiation weighting factor, formerly the quality factor Q) expresses long-term risk (primarily cancer and leukemia) from low-level chronic exposure. It depends upon the type of radiation and other factors, as follows [2]:

Table 25.1: Radiation weighting factors.

Radiation	w_R
X - and γ -rays, all energies	1
Electrons and muons, all energies	1
Neutrons < 10 keV	5
10-100 keV	10
$> 100 \mathrm{\ keV}$ to 2 MeV	20
$2-20~{ m MeV}$	10
$> 20 \mathrm{MeV}$	5
Protons (other than recoils) > 2 MeV	5
Alphas, fission fragments, & heavy nuclei	20

25.2. Radiation levels [3]

- Natural annual background, all sources: Most world areas, whole-body equivalent dose rate $\approx (0.4\text{--}4)$ mSv (40–400 millirems). Can range up to 50 mSv (5 rems) in certain areas. U.S. average ≈ 3.6 mSv, including ≈ 2 mSv (≈ 200 mrem) from inhaled natural radioactivity, mostly radon and radon daughters (0.1–0.2 mSv in open areas. Average is for a typical house and varies by more than an order of magnitude. It can be more than two orders of magnitude higher in poorly ventilated mines).
- Cosmic ray background in counters (Earth's surface): $\sim 1~{\rm min^{-1}~cm^{-2}}$ sr. For more accurate estimates and details, see the Cosmic Rays section (Sec. 20 of this Review).
- Fluxes (per cm²) to deposit one Gy, assuming uniform irradiation: $\approx (\text{charged particles}) 6.24 \times 10^9/(dE/dx)$, where dE/dx (MeV g⁻¹ cm²), the energy loss per unit length, may be obtained from the Mean Range and Energy Loss figures.
- $\approx 3.5 \times 10^9~{\rm cm}^{-2}$ minimum-ionizing singly-charged particles in carbon.
- $\approx ({\bf photons})~6.24\times 10^9/[Ef/\lambda],$ for photons of energy E (MeV), attenuation length λ (g cm $^{-2})$ (see Photon Attenuation Length

figure), and fraction $f\lesssim 1$ expressing the fraction of the photon's energy deposited in a small volume of thickness $\ll \lambda$ but large enough to contain the secondary electrons.

 $\approx 2\times 10^{11}~\rm photons~cm^{-2}~for~1~MeV~photons~on~carbon~(\it f\approx 1/2).$

(Quoted fluxes are good to about a factor of 2 for all materials.)

ullet Recommended limits to exposure of radiation workers (whole-body dose):*

CERN: 15 mSv yr⁻¹ **U.K.:** 15 mSv yr⁻¹

U.S.: 50 mSv yr⁻¹ (5 rem yr⁻¹) †

• Lethal dose: Whole-body dose from penetrating ionizing radiation resulting in 50% mortality in 30 days (assuming no medical treatment) 2.5–3.0 Gy (250–300 rads), as measured internally on body longitudinal center line. Surface dose varies due to variable body attenuation and may be a strong function of energy.

25.3. Prompt neutrons at accelerators

25.3.1. Electron beams: At electron accelerators neutrons are generated via photonuclear reactions from bremsstrahlung photons. Neutron yields from semi-infinite targets per unit electron beam power are plotted in Fig. 25.1 as a function of electron beam energy [4]. In the photon energy range 10–30 MeV neutron production results from the giant photonuclear resonance mechanism. Neutrons are produced roughly isotropically (within a factor of 2) and with a Maxwellian energy distribution described as:

$$\frac{dN}{dE_n} = \frac{E_n}{T^2} e^{-E_n/T} \ , \tag{25.1}$$

where T is the nuclear temperature characteristic of the target nucleus, generally in the range of T=0.5–1.0 MeV. For higher energy photons the quasi-deuteron and photopion production mechanisms become important.

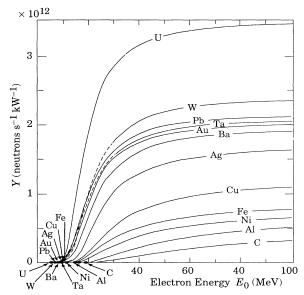

Figure 25.1: Neutron yields from semi-infinite targets, per kW of electron beam power, as a function of electron beam energy, disregarding target self-shielding.

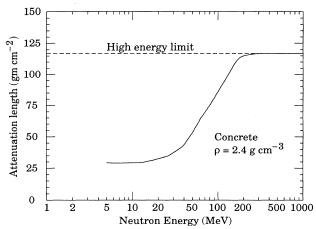

Figure 25.3: The variation of the attenuation length for monoenergetic neutrons in concrete as a function of neutron energy [5].

25.3.2. *Proton beams*: At proton accelerators neutron yields emitted per incident proton by different target materials are roughly independent [5] of proton energy between 20 MeV and 1 GeV and are given by the ratio C:Al:Cu-Fe:Sn:Ta-Pb = 0.3:0.6:1.0:1.5:1.7. Above 1 GeV neutron yield [6] is proportional to E^m , where $0.80 \le m \le 0.85$.

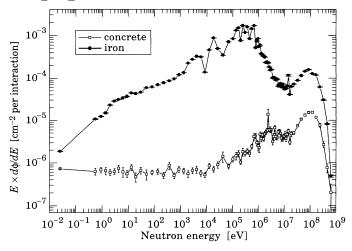

Figure 25.2: Calculated neutron spectrum from 205 GeV/c hadrons (2/3 protons and 1/3 π^+) on a thick copper target. Spectra are evaluated at 90° to beam and through 80 cm of normal density concrete or 40 cm of iron.

A typical neutron spectrum [7] outside a proton accelerator concrete shield is shown in Fig. 25.2. The shape of these spectra are generally characterized as having a thermal-energy peak which is very dependent on geometry and the presence of hydrogenic material, a low-energy evaporation peak around 2 MeV, and a high-energy spallation shoulder.

Letaw's [8] formula for the energy dependence of the inelastic proton cross-section (asymptotic values given in Table 6.1) for E < 2 GeV is:

$$\sigma(E) = \sigma_{\text{asympt}} \left[1 - 0.62e^{-E/200} \sin(10.9E^{-0.28}) \right] ,$$
 (25.2)

and for E > 2 GeV:

$$\sigma_{\text{asympt}} = 45A^{0.7} [1 + 0.016 \sin(5.3 - 2.63 \ln A)] ,$$
 (25.3)

where σ is in mb, E is the proton energy in MeV and A is the mass number.

The neutron-attenuation length, λ , is shown in Fig. 25.3 for monoenergetic broad-beam conditions. These values give a satisfactory representation at depths greater than 1 m in concrete.

25.4. Dose conversion factors

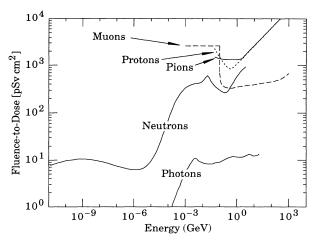

Figure 25.4: Fluence to dose equivalent conversion factors for various particles.

Fluence to dose equivalent factors are given in Fig. 25.4 for photons [9], neutrons [10], muons [11], protons and pions [12]. These factors can be used for converting particle fluence to dose for personnel protection purposes.

25.5. Accelerator-induced activity

The dose rate at 1 m due to spallation-induced activity by high energy hadrons in a 1 g medium atomic weight target can be estimated [13] from the following expression:

$$D = D_0 \Phi \ln[(T+t)/t] , \qquad (25.4)$$

where T is the irradiation time, t is the decay time since irradiation, Φ is the flux of irradiating hadrons (hadrons cm⁻² s⁻¹) and D_0 has a value of 5.2×10^{-17} [(Sv hr⁻¹)/(hadron cm⁻² s⁻¹)]. This relation is essentially independent of hadron energy above 200 MeV.

Dose due to accelerator-produced induced activity can also be estimated with the use of " ω factors" [5]. These factors give the dose rate per unit star density (inelastic reaction for E > 50 MeV) after a 30 day irradiation and 1 day decay. The ω factors for concrete and steel are 1.2×10^{-8} (Sv cm³/star) and 4.5×10^{-8} (Sv cm³/star), respectively. These do not include contributions from thermal-neutron activation. This can vary widely depending on concrete composition, particularly with the concentration of trace quantities such as sodium. Additional information can be found in Barbier [14].

25.6. Photon sources

The dose rate from a gamma point source of C Curies emitting one photon of energy 0.07 < E < 4 MeV per disintegration at a distance of 30 cm is 6CE (rem/hr), or 60CE (mSv/hr), $\pm 20\%$.

The dose rate from a semi-infinite uniform photon source of specific activity C (μ Ci/g) and gamma energy E (MeV) is 1.07CE (rem/hr), or 10.7CE (mSv/hr).

25.7. Radiation levels in detectors at hadron colliders

An SSC Central Design Group task force studied the radiation levels to be expected in SSC detectors [15]. The study focused on scaling with energy, distance, and angle. As such, it is applicable to future detectors such as those at the LHC. Although superior detector-specific calculations have since been made, the scaling is in most cases not evident, and so the SSC results have some relevance. The SSC/CDG model assumed

- The machine luminosity at $\sqrt{s}=40$ TeV is $\mathscr{L}=10^{33}$ cm⁻²s⁻¹, and the pp inelastic cross section is $\sigma_{\rm inel}=100$ mb. This luminosity is effectively achieved for 10^7 s yr⁻¹. The interaction rate is thus 10^8 s⁻¹, or 10^{15} yr⁻¹;
- All radiation comes from pp collisions at the interaction point;
- The charged particle distribution is (a) flat in pseudorapidity for $|\eta| < 6$ and (b) has a momentum distribution whose perpendicular component is independent of rapidity, which is taken as independent of pseudorapidity:

$$\frac{d^2 N_{\rm ch}}{d\eta dp_{\perp}} = H f(p_{\perp}) \tag{25.5}$$

(where $p_{\perp} = p \sin \theta$). Integrals involving $f(p_{\perp})$ are simplified by replacing $f(p_{\perp})$ by $\delta(p_{\perp} - \langle p_{\perp} \rangle)$; in the worst case this approximation introduces an error of less than 10%;

- Gamma rays from π^0 decay are as abundant as charged particles. They have approximately the same η distribution, but half the mean momentum:
- At the SSC ($\sqrt{s}=40$ TeV), $H\approx 7.5$ and $\langle p_{\perp}\rangle\approx 0.6$ GeV/c; assumed values at other energies are given in Table 25.3. Together with the model discussed above, these values are thought to describe particle production to within a factor of two or better.

It then follows that the flux of charged particles from the interaction point passing through a normal area da located a distance r_{\perp} from the beam line is given by

$$\frac{dN_{\rm ch}}{da} = \frac{1.2 \times 10^8 \,\mathrm{s}^{-1}}{r_\perp^2} \ . \tag{25.6}$$

In a typical organic material, a relativistic charged particle flux of $3 \times 10^9 \text{ cm}^{-2}$ produces an ionizing radiation dose of 1 Gy, where 1 Gy \equiv 1 joule kg⁻¹ (= 100 rads). The above result may thus be rewritten as dose rate.

$$\dot{D} = \frac{0.4 \text{ MGy yr}^{-1}}{(r_{\perp}/1 \text{ cm})^2} \ . \tag{25.7}$$

If a magnetic field is present, "loopers" may increase this dose rate by a factor of two ore more.

In a medium in which cascades can develop, the ionizing dose or neutron fluence is proportional to $dN_{\rm ch}/da$ multiplied by $\langle E \rangle^{\alpha}$, where $\langle E \rangle$ is the mean energy of the particles going through da and the power α is slightly less than unity. Since $E \approx p = p_{\perp}/\sin\theta$ and $r_{\perp} = r\sin\theta$, the above expression for $dN_{\rm ch}/da$ becomes

Dose or fluence
$$= \frac{A}{r^2} \cosh^{2+\alpha} \eta = \frac{A}{r^2 \sin^{2+\alpha} \theta}$$
. (25.8)

The constant A contains the total number of interactions $\sigma_{\rm inel} \int \mathscr{L} dt$, so the ionizing dose or neutron fluence at another accelerator scales as $\sigma_{\rm inel} \int \mathscr{L} dt \, H \, \langle p_{\perp} \rangle^{\alpha}$.

The dose or fluence in a calorimeter scales as $1/r^2$, as does the neutron fluence inside a central cavity with characteristic dimension r.

Under all conditions so far studied, the neutron spectrum shows a broad log-normal distribution peaking at just under 1 MeV. In a 2 m radius central cavity of a detector with coverage down to $|\eta|=3$, the average neutron flux is $2\times 10^{12}~{\rm cm}^{-2}{\rm yr}^{-1}$, including secondary scattering contributions.

Values of A and α are given in Table 25.2 for several relevant situations. Examples of scaling to other accelerators are given in Table 25.3. It should be noted that the assumption that all radiation comes from the interaction point does not apply to the present generation of accelerators.

The constant A includes factors evaluated with cascade simulation programs as well as constants describing particle production at the interaction point. It is felt that each could introduce an error as large as a factor of two in the results.

Table 25.2: Coefficients $A/(100 \text{ cm})^2$ and α for the evaluation of calorimeter radiation levels at cascade maxima under SSC nominal operating conditions. At a distance r and angle θ from the interaction point the annual fluence or dose is $A/(r^2 \sin^{2+\alpha} \theta)$.

Quantity	$A/(100 { m cm})^2$	Units	$\langle p_{\perp} \rangle$	α
Neutron flux	1.5×10^{12}	$\mathrm{cm}^{-2}\mathrm{yr}^{-1}$	$0.6~{ m GeV}/c$	0.67
Dose rate from photons	124	$\rm Gy~\rm yr^{-1}$	$0.3~{ m GeV}/c$	0.93
Dose rate from hadrons	29	$\mathrm{Gy}\ \mathrm{yr}^{-1}$	$0.6~{ m GeV}/c$	0.89

Table 25.3: A rough comparison of beam-collision induced radiation levels at the Tevatron, high-luminosity LHC, SSC, and a possible 100 TeV machine [16].

Tevatron	LHC	SSC	$100 \mathrm{TeV}$

"Emission probability" is the probability per decay of a given emission; because of cascades these may total more than 100%. Only principal emissions are listed. EC means electron capture, and e^- means monoenergetic internal conversion (Auger) electron. The intensity of 0.511 MeV e^+e^- annihilation photons depends upon the number of stopped positrons. Endpoint β^\pm energies are listed. In some cases when energies are closely spaced, the γ -ray values are approximate weighted averages. Radiation from short-lived daughter isotopes is included where relevant.

Half-lives, energies, and intensities are from E. Browne and R.B. Firestone, *Table of Radioactive Isotopes* (John Wiley & Sons, New York, 1986), recent *Nuclear Data Sheets*, and *X-ray and Gamma-ray Standards for Detector Calibration*, IAEA-TECDOC-619 (1991).

Neutron data are from Neutron Sources for Basic Physics and Applications (Pergamon Press, 1983).

27. PROBABILITY

Revised May 1996.

27.1. General [1-5]

Let x be a possible outcome of an observation. The probability of x is the relative frequency with which that outcome occurs out of a (possibly hypothetical) large set of similar observations. If x can take any value from a continuous range, we write $f(x;\theta)$ dx as the probability of observing x between x and x+dx. The function $f(x;\theta)$ is the probability density function (p.d.f.) for the random variable x, which may depend upon one or more parameters θ . If x can take on only discrete values (e.g., the non-negative integers), then $f(x;\theta)$ is itself a probability, but we shall still call it a p.d.f. The p.d.f. is always normalized to unit area (unit sum, if discrete). Both x and θ may have multiple components and are then often written as column vectors. If θ is unknown and we wish to estimate its value from a given set of data measuring x, we may use statistics (see Sec. 28).

The cumulative distribution function F(a) is the probability that $x \leq a$:

$$F(a) = \int_{-\infty}^{a} f(x) dx$$
 (27.1)

Here and below, if x is discrete-valued, the integral is replaced by a sum. The endpoint a is expressly included in the integral or sum. Then $0 \le F(x) \le 1$, F(x) is nondecreasing, and $\operatorname{Prob}(a < x \le b) = F(b) - F(a)$. If x is discrete, F(x) is flat except at allowed values of x, where it has discontinuous jumps equal to f(x).

Any function of random variables is itself a random variable, with (in general) a different p.d.f. The *expectation value* of any function u(x) is

$$E[u(x)] = \int_{-\infty}^{\infty} u(x) f(x) dx$$
, (27.2)

assuming the integral is finite. For u(x) and v(x) any two functions of x, E(u+v)=E(u)+E(v). For c and k constants, E(cu+k)=cE(u)+k.

The nth moment of a distribution is

$$\alpha_n \equiv E(x^n) = \int_{-\infty}^{\infty} x^n f(x) dx , \qquad (27.3a)$$

and the nth moment about the mean of x, α_1 , is

$$m_n \equiv E[(x - \alpha_1)^n] = \int_{-\infty}^{\infty} (x - \alpha_1)^n f(x) dx . \qquad (27.3b)$$

The most commonly used moments are the mean μ and variance σ^2 :

$$\mu \equiv \alpha_1 \tag{27.4a}$$

$$\sigma^2 \equiv \operatorname{Var}(x) \equiv m_2 = \alpha_2 - \mu^2 \ . \tag{27.4b}$$

The mean is the location of the "center of mass" of the probability density function, and the variance is a measure of the square of its width. Note that $Var(cx + k) = c^2 Var(x)$.

Any odd moment about the mean is a measure of the skewness of the p.d.f. The simplest of these is the dimensionless coefficient of skewness $\gamma_1 \equiv m_3/\sigma^3$.

Besides the mean, another useful indicator of the "middle" of the probability distribution is the $median \, x_{\rm med}$, defined by $F(x_{\rm med}) = 1/2; \, i.e.$, half the probability lies above and half lies below $x_{\rm med}$. For a given sample of events, $x_{\rm med}$ is the value such that half the events have larger x and half have smaller x (not counting any that have the same x as the median). If the sample median lies between two observed x values, it is set by convention halfway between them. If the p.d.f. for x has the form $f(x-\mu)$ and μ is both mean and median, then for a large number of events N, the variance of the median approaches $1/[4Nf^2(0)]$, provided f(0) > 0.

Let x and y be two random variables with a joint p.d.f. f(x,y). The marginal p.d.f. of x (the distribution of x with y unobserved) is

$$f_1(x) = \int_{-\infty}^{\infty} f(x, y) \, dy$$
, (27.5)

and similarly for the marginal p.d.f. $f_2(y)$. We define the *conditional* p.d.f. of x, given fixed y, by

$$f_3(y|x) f_1(x) = f(x,y)$$
 (27.6a)

Similarly, the conditional p.d.f. of y, given fixed x, is

$$f_4(x|y) f_2(y) = f(x,y)$$
. (27.6b)

From these definitions we immediately obtain Bayes' theorem [2]:

$$f_4(x|y) = \frac{f_3(y|x) f_1(x)}{f_2(y)} = \frac{f_3(y|x) f_1(x)}{\int f_3(y|x) f_1(x) dx} . \tag{27.7}$$

The mean of x is

$$\mu_x = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \, f(x, y) \, dx \, dy = \int_{-\infty}^{\infty} x \, f_1(x) \, dx \,, \tag{27.8}$$

and similarly for y. The *correlation* between x and y is a measure of the dependence of one on the other:

$$\rho_{xy} = E\left[(x - \mu_x)(y - \mu_y) \right] / \sigma_x \, \sigma_y = \operatorname{Cov}(x, y) / \sigma_x \, \sigma_y , \qquad (27.9)$$

where σ_x and σ_y are defined in analogy with Eq. (27.4b). It can be shown that $-1 \le \rho_{xy} \le 1$. Here "Cov" is the covariance of x and y, a 2-dimensional analogue of the variance.

Two random variables are independent if and only if

$$f(x,y) = f_1(x) f_2(y) . (27.10)$$

If x and y are independent then $\rho_{xy}=0$; the converse is not necessarily true except for Gaussian-distributed x and y. If x and y are independent, $E[u(x)\ v(y)]=E[u(x)]\ E[v(y)]$, and $\mathrm{Var}(x+y)=\mathrm{Var}(x)+\mathrm{Var}(y)$; otherwise, $\mathrm{Var}(x+y)=\mathrm{Var}(x)+\mathrm{Var}(y)+2\mathrm{Cov}(x,y)$, and $E(u\ v)$ does not factor.

In a change of continuous random variables from $\mathbf{x} \equiv (x_1, \ldots, x_n)$, with p.d.f. $f(\mathbf{x}) = f(x_1, \ldots, x_n)$, to $\mathbf{y} \equiv (y_1, \ldots, y_n)$, a one-to-one function of the x_i 's, the p.d.f. $g(\mathbf{y}) = g(y_1, \ldots, y_n)$ is found by substitution for (x_1, \ldots, x_n) in f followed by multiplication by the absolute value of the Jacobian of the transformation; that is,

$$g(\mathbf{y}) = f\left[w_1(\mathbf{y}), \dots, w_n(\mathbf{y})\right] |J| . \qquad (27.11)$$

The functions w_i express the *inverse* transformation, $x_i = w_i(\boldsymbol{y})$ for i = 1, ..., n, and |J| is the absolute value of the determinant of the square matrix $J_{ij} = \partial x_i/\partial y_j$. If the transformation from \boldsymbol{x} to \boldsymbol{y} is not one-to-one, the situation is more complex and a unique solution may not exist. For example, if the change is to m < n variables, then a given \boldsymbol{y} may correspond to more than one \boldsymbol{x} , leading to multiple integrals over the contributions [1].

To change variables for discrete random variables simply substitute; no Jacobian is necessary because now f is a probability rather than a probability density.

If f depends upon a parameter set α , a change to a different parameter set $\phi_i = \phi_i(\alpha)$ is made by simple substitution; no Jacobian is used

27.2. Characteristic functions

The characteristic function $\phi(u)$ associated with the p.d.f. f(x) is essentially its (inverse) Fourier transform, or the expectation value of $\exp(iux)$:

$$\phi(u) = E(e^{iux}) = \int_{-\infty}^{\infty} e^{iux} f(x) dx . \qquad (27.12)$$

It is often useful, and several of its properties follow [1].

It follows from Eqs. (27.3a) and (27.12) that the *n*th moment of the distribution f(x) is given by

$$i^{-n}\frac{d^n\phi}{du^n}\bigg|_{u=0} = \int_{-\infty}^{\infty} x^n f(x) dx = \alpha_n . \qquad (27.13)$$

Thus it is often easy to calculate all the moments of a distribution defined by $\phi(u)$, even when f(x) is difficult to obtain.

If $f_1(x)$ and $f_2(y)$ have characteristic functions $\phi_1(u)$ and $\phi_2(u)$, then the characteristic function of the weighted sum ax + by is $\phi_1(au)\phi_2(bu)$. The addition rules for common distributions (e.g., that the sum of two numbers from Gaussian distributions also has a Gaussian distribution) easily follow from this observation.

Let the (partial) characteristic function corresponding to the conditional p.d.f. $f_2(x|z)$ be $\phi_2(u|z)$, and the p.d.f. of z be $f_1(z)$. The characteristic function after integration over the conditional value is

$$\phi(u) = \int \phi_2(u|z) f_1(z) dz . \qquad (27.14)$$

Suppose we can write ϕ_2 in the form

$$\phi_2(u|z) = A(u)e^{ig(u)z} . (27.15)$$

Then

$$\phi(u) = A(u)\phi_1(g(u)) . (27.16)$$

The semi-invariants κ_n are defined by

$$\phi(u) = \exp\left(\sum_{1}^{\infty} \frac{\kappa_n}{n!} (iu)^n\right) = \exp\left(i\kappa_1 u - \frac{1}{2}\kappa_2 u^2 + \ldots\right) . (27.17)$$

The κ_n 's are related to the moments α_n and m_n . The first few relations are

$$\kappa_1=\alpha_1~(=\mu,\,{\rm the\ mean})$$

$$\kappa_2=m_2~=\alpha_2-\alpha_1^2~(=\sigma^2,\,{\rm the\ variance})$$

$$\kappa_3=m_3=\alpha_3-3\alpha_1\alpha_2+2\alpha_1^2~. \tag{27.18}$$

27.3. Some probability distributions

Table 27.1 gives a number of common probability density functions and corresponding characteristic functions, means, and variances. Further information may be found in Refs. 1–6; Ref. 6 has particularly detailed tables. Monte Carlo techniques for generating each of them may be found in our Sec. 29.4. We comment below on all except the trivial uniform distribution.

27.3.1. Binomial distribution: A random process with exactly two possible outcomes is called a Bernoulli process. If the probability of obtaining a certain outcome (a "success") in each trial is p, then the probability of obtaining exactly r successes $(r=0,1,2,\ldots,n)$ in n trials, without regard to the order of the successes and failures, is given by the binomial distribution f(r;n,p) in Table 27.1. If r successes are observed in n_r trials with probability p of a success, and if s successes are observed in n_s similar trials, then t=r+s is also binomial with $n_t=n_r+n_s$.

27.3.2. Poisson distribution: The Poisson distribution $f(r; \mu)$ gives the probability of finding exactly r events in a given interval of x (e.g., space and time) when the events occur independently of one another and of x at an average rate of μ per the given interval. The variance σ^2 equals μ . It is the limiting case $p \to 0$, $n \to \infty$, $np = \mu$ of the binomial distribution. The Poisson distribution approaches the Gaussian distribution for large μ .

Two or more Poisson processes (e.g., signal + background, with parameters μ_s and μ_b) that independently contribute amounts n_s and n_b to a given measurement will produce an observed number $n = n_s + n_b$, which is distributed according to a new Poisson distribution with parameter $\mu = \mu_s + \mu_b$.

27.3.3. Normal or Gaussian distribution: The normal (or Gaussian) probability density function $f(x; \mu, \sigma^2)$ given in Table 27.1 has mean $\overline{x} = \mu$ and variance σ^2 . Comparison of the characteristic function $\phi(u)$ given in Table 27.1 with Eq. (27.17) shows that all semi-invariants κ_n beyond κ_2 vanish; this is a unique property of the Gaussian distribution. Some properties of the distribution are:

```
rms deviation = \sigma probability x in the range \mu \pm \sigma = 0.6827 probability x in the range \mu \pm 0.6745\sigma = 0.5 expection value of |x - \mu|, E(|x - \mu|) = (2/\pi)^{1/2}\sigma = 0.7979\sigma half-width at half maximum = (2 \ln 2)^{1/2}\sigma = 1.177\sigma
```

The cumulative distribution, Eq. (27.1), for a Gaussian with $\mu=0$ and $\sigma^2=1$ is related to the error function $\mathrm{erf}(y)$ by

$$F(x;0,1) = \frac{1}{2} \left[1 + \operatorname{erf}(x/\sqrt{2}) \right] . \tag{27.19}$$

The error function is tabulated in Ref. 6 and is available in computer math libraries and personel computer spreadsheets. For a mean μ and variance σ^2 , replace x by $(x - \mu)/\sigma$. The probability of x in a given range can be calculated with Eq. (28.34).

For x and y independent and normally distributed, z = ax + by obeys $f(z; a\mu_x + b\mu_y, a^2\sigma_x^2 + b^2\sigma_y^2)$; that is, the weighted means and variances add.

The Gaussian gets its importance in large part from the central limit theorem: If a continuous random variable x is distributed according to any p.d.f. with finite mean and variance, then the sample mean, \overline{x}_n , of n observations of x will have a p.d.f. that approaches a Gaussian as n increases. Therefore the end result $\sum^n x_i \equiv n\overline{x}_n$ of a large number of small fluctuations x_i will be distributed as a Gaussian, even if the x_i themselves are not.

For a set of n Gaussian random variables x with means μ and corresponding Fourier variables u, the characteristic function for a one-dimensional Gaussian is generalized to

$$\phi(\mathbf{x}; \boldsymbol{\mu}, S) = \exp\left[i\boldsymbol{\mu} \cdot \boldsymbol{u} - \frac{1}{2}\boldsymbol{u}^T S \boldsymbol{u}\right] . \tag{27.20}$$

From Eq. (27.13), the covariance about the mean is

$$E[(x_j - \mu_j)(x_k - \mu_k)] = S_{jk}. (27.21)$$

If the x are independent, then $S_{jk}=\delta_{jk}\sigma_j^2$, and Eq. (27.20) is the product of the c.f.'s of n Gaussians.

The covariance matrix S can be related to the correlation matrix defined by Eq. (27.9) (a sort of normalized covariance matrix). With the definition $\sigma_k^2 \equiv S_{kk}$, we have $\rho_{jk} = S_{jk}/\sigma_j\sigma_k$.

The characteristic function may be inverted to find the corresponding p.d.f.

$$f(\mathbf{x}; \boldsymbol{\mu}, S) = \frac{1}{(2\pi)^{n/2} \sqrt{|S|}} \exp \left[-\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})^T S^{-1} (\mathbf{x} - \boldsymbol{\mu}) \right], (27.22)$$

where the determinant |S| must be greater than 0. For diagonal S (independent variables), $f(x; \mu, S)$ is the product of the p.d.f.'s of n Gaussian distributions.

Distribution	Probability density function f (variable; parameters)	Characteristic function $\phi(u)$	Mean	Variance σ
Uniform	$f(x; a, b) = \begin{cases} 1/(b-a) & a \le x \le b \\ 0 & \text{otherwise} \end{cases}$	$\frac{e^{ibu} - e^{iau}}{(b-a)iu}$	$\overline{x} = \frac{a+b}{2}$	$\frac{(b-a)^2}{12}$
Binomial	$f(r; n, p) = \frac{n!}{r!(n-r)!} p^r q^{n-r}$ $r = 0, 1, 2, \dots, n ; 0 \le p \le 1 ; q = 1-p$	$(q+pe^{iu})^n$	$\overline{r}=np$	npq
Poisson	$f(r;\mu) = \frac{\mu^r e^{-\mu}}{r!} \; ; r = 0, 1, 2, \dots \; ; \mu > 0$	$\exp[\mu(e^{iu}-1)]$	$\overline{r}=\mu$	μ
Normal (Gaussian)	$f(x; \mu, \sigma^2) = \frac{1}{\sigma\sqrt{2\pi}} \exp(-(x - \mu)^2/2\sigma^2)$ $-\infty < x < \infty ; -\infty < \mu < \infty ; \sigma > 0$	$\exp(i\mu u - \frac{1}{2}\sigma^2 u^2)$	$\overline{x} = \mu$	σ^2
Multivariate Gaussian	$f(\boldsymbol{x};\boldsymbol{\mu},S) = \frac{1}{(2\pi)^{n/2}\sqrt{ S }}$	$\exp\left[i\boldsymbol{\mu}\cdot\boldsymbol{u}-\frac{1}{2}\boldsymbol{u}^TS\boldsymbol{u}\right]$	μ	S_{jk}
	$\times \exp\left[-\frac{1}{2}(\boldsymbol{x} - \boldsymbol{\mu})^T S^{-1}(\boldsymbol{x} - \boldsymbol{\mu})\right]$ $-\infty < x_j < \infty; -\infty < x_j < \infty; \det S > 0$			
χ^2	$f(z;n) = \frac{z^{n/2-1}e^{-z/2}}{2^{n/2}\Gamma(n/2)}$; $z \ge 0$	$(1-2iu)^{-n/2}$	$\overline{z}=n$	2n
Student's t	$f(t;n) = \frac{1}{\sqrt{n\pi}} \frac{\Gamma[(n+1)/2]}{\Gamma(n/2)} \left(1 + \frac{t^2}{n}\right)^{-(n+1)/2}$ $-\infty < t < \infty ; \qquad n \text{ not required to be integer}$		$\bar{t} = 0$ for $n \ge 2$	$n/(n-2)$ for $n \ge 3$
Gamma	$f(x; \lambda, k) = rac{x^{k-1} \lambda^k e^{-\lambda x}}{\Gamma(k)} \; ; 0 < x < \infty \; ;$ $k \; ext{not required to be integer}$	$(1-iu/\lambda)^{-k}$	$\overline{x} = k/\lambda$	k/λ^2

Table 27.1: Some common probability density functions, with corresponding characteristic functions and means and variances. In the Table, $\Gamma(k)$ is the gamma function, equal to (k-1)! when k is an integer.

For n = 2, $f(\boldsymbol{x}; \boldsymbol{\mu}, S)$ is

$$f(x_1, x_2; \ \mu_1, \mu_2, \sigma_1, \sigma_2, \rho) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}$$

$$\times \exp\left\{\frac{-1}{2(1-\rho^2)} \left[\frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2} \right] \right\}. \tag{27.23}$$

The marginal distribution of any x_i is a Gaussian with mean μ_i and variance S_{ii} . S is $n \times n$, symmetric, and positive definite. Therefore for any vector \mathbf{X} , the quadratic form $\mathbf{X}^T S^{-1} \mathbf{X} = C$, where C is any positive number, traces an n-dimensional ellipsoid as \mathbf{X} varies. If $X_i = (x_i - \mu_i)/\sigma_i$, then C is a random variable obeying the $\chi^2(n)$ distribution, discussed in the following section. The probability that \mathbf{X} corresponding to a set of Gaussian random variables x_i lies outside the ellipsoid characterized by a given value of $C = \chi^2$ is given by Eq. (27.24) and may be read from Fig. 27.1. For example, the "s-standard-deviation ellipsoid" occurs at $C = s^2$. For the two-variable case (n=2), the point \mathbf{X} lies outside the one-standard-deviation ellipsoid with 61% probability. (This assumes that μ_i and σ_i are correct.) For $X_i = x_i/\sigma_i$, the ellipsoids of constant χ^2 have the same size and orientation but are centered at μ . The use of these ellipsoids as indicators of probable error is described in Sec. 28.6.1.

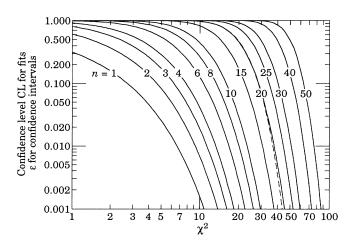

Figure 27.1: The confidence level versus χ^2 for n degrees of freedom, as defined in Eq. (27.24). The curve for a given n gives the probability that a value at least as large as χ^2 will be obtained in an experiment; e.g., for n=10, a value $\chi^2\gtrsim 18$ will occur in 5% of a large number of experiments. For a fit, the CL is a measure of goodness-of-fit, in that a good fit to a correct model is expected to yield a low χ^2 (see Sec. 28.5.0). For a confidence interval, α measures the probability that the interval does not cover the true value of the quantity being estimated (see Sec. 28.6). The dashed curve for n=20 is calculated using the approximation of Eq. (27.25).

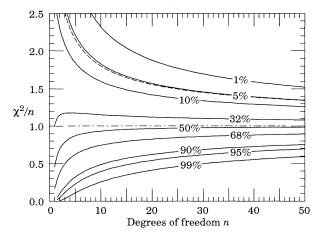

Figure 27.3: Confidence levels as a function of the "reduced χ^2 " $\equiv \chi^2/n$ and the number of degrees of freedom n. Curves are labeled by the probability that a measurement will give a value of χ^2/n greater than that given on the y axis; e.g., for n=10, a value $\chi^2/n \gtrsim 1.8$ can be expected 5% of the time.

27.3.4. χ^2 distribution: If x_1, \ldots, x_n are independent Gaussian distributed random variables, the sum $z = \sum^n (x_i - \mu_i)^2 / \sigma_i^2$ is distributed as a χ^2 with n degrees of freedom, $\chi^2(n)$. Under a linear transformation to n dependent Gaussian variables x_i' , the χ^2 at each transformed point retains its value; then $z = \mathbf{X}'^T V^{-1} \mathbf{X}'$ as in the previous section. For a set of z_i , each of which is $\chi^2(n_i)$, $\sum z_i$ is a new random variable which is $\chi^2(\sum n_i)$.

Fig. 27.1 shows the confidence level (CL) obtained by integrating the tail of f(z; n):

$$CL(\chi^2) = \int_{\chi^2}^{\infty} f(z; n) dz$$
 (27.24)

This is shown for a special case in Fig. 27.2, and is equal to 1.0 minus the cumulative distribution function $F(z=\chi^2;n)$. It is useful in evaluating the consistency of data with a model (see Sec. 28): The CL is the probability that a random repeat of the given experiment would observe a greater χ^2 , assuming the model is correct. It is also useful for confidence intervals for statistical estimators (see Sec. 28.6), in which case one is interested in the unshaded area of Fig. 27.2.

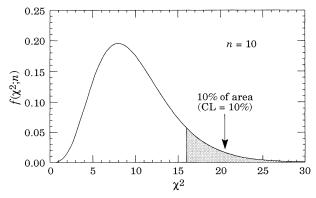

Figure 27.2: Illustration of the confidence level integral given in Eq. (27.24). This particlar example is for n = 10, where the area above 15.99 is 0.1.

Since the mean of the χ^2 distribution is equal to n, one expects in a "reasonable" experiment to obtain $\chi^2 \approx n$. While caution is necessary because of the width and skewness of the distribution, the "reduced χ^2 " $\equiv \chi^2/n$ is a sometimes useful quantity. Figure 27.3 shows χ^2/n for useful CL's as a function of n.

For large n, the CL is approximately given by [1,7]

$$CL(\chi^2) \approx \frac{1}{\sqrt{2\pi}} \int_y^\infty e^{-x^2/2} dx$$
, (27.25)

where $y = \sqrt{2\chi^2} - \sqrt{2n-1}$. This approximation was used to draw the dashed curves in Fig. 27.1 (for n=20) and Fig. 27.3 (for CL = 5%). Since all the functions and their inverses are now readily available in standard mathematical libraries (such as IMSL, used to generate these figures, and personal computer spreadsheets, such as Microsoft (Excel [8]), the approximation (and even figures and tables) are seldom needed.

27.3.5. Student's t distribution: Suppose that x and x_1, \ldots, x_n are independent and Gaussian distributed with mean 0 and variance 1. We then define

$$z = \sum_{i=1}^{n} x_i^2$$
, and $t = \frac{x}{\sqrt{z/n}}$. (27.26)

The variable z thus belongs to a $\chi^2(n)$ distribution. Then t is distributed according to a Student's t distribution with n degrees of freedom, f(t;n), given in Table 27.1.

The Student's t distribution resembles a Gaussian distribution with wide tails. As $n \to \infty$, the distribution approaches a Gaussian. If n=1, the distribution is a *Cauchy* or *Breit-Wigner* distribution. The mean is finite only for n>1 and the variance is finite only for n>2, so for n=1 or n=2, t does not obey the central limit theorem.

As an example, consider the sample mean $\overline{x} = \sum x_i/n$ and the sample variance $s^2 = \sum (x_i - \overline{x})^2/(n-1)$ for normally distributed random variables x_i with unknown mean μ and variance σ^2 . The sample mean has a Gaussian distribution with a variance σ^2/n , so the variable $(\overline{x} - \mu)/\sqrt{\sigma^2/n}$ is normal with mean 0 and variance 1. Similarly, $(n-1) s^2/\sigma^2$ is independent of this and is χ^2 distributed with n-1 degrees of freedom. The ratio

$$t = \frac{(\overline{x} - \mu)/\sqrt{\sigma^2/n}}{\sqrt{(n-1)\ s^2/\sigma^2\ (n-1)}} = \frac{\overline{x} - \mu}{\sqrt{s^2/n}}$$
(27.27)

is distributed as f(t; n-1). The unknown true variance σ^2 cancels, and t can be used to test the probability that the true mean is some particular value μ .

In Table 27.1, n in f(t;n) is not required to be an integer. A Student's t distribution with nonintegral n>0 is useful in certain applications.

27.3.6. Gamma distribution: For a process that generates events as a function of x (e.g., space or time) according to a Poisson distribution, the distance in x from an arbitrary starting point (which may be some particular event) to the k^{th} event belongs to a gamma distribution, $f(x; \lambda, k)$. The Poisson parameter μ is λ per unit x. The special case k = 1 (i.e., $f(x; \lambda, 1) = \lambda e^{-\lambda x}$) is called the exponential distribution. A sum of k' exponential random variables x_i is distributed as $f(\sum x_i; \lambda, k')$.

The parameter k is not required to be an integer. For $\lambda = 1/2$ and k = n/2, the gamma distribution reduces to the $\chi^2(n)$ distribution.

28. STATISTICS

Revised May 1996.

28.1. General [1-6]

A probability density function with known parameters enables us to predict the frequency with which a random variable will take on a particular value (if discrete) or lie in a given range (if continuous). In parametric statistics we have the opposite problem of estimating the parameters of the p.d.f. from a set of actual observations.

We refer to the true p.d.f. as the *population*; the data form a *sample* from this population. A *statistic* is any function of the data, plus known constants, which does not depend upon any of the unknown parameters. A statistic is a random variable if the data have random errors. An *estimator* is any statistic whose value is intended as a meaningful guess for the value of an unknown parameter; we denote estimators with hats, e.g., $\widehat{\alpha}$.

Often it is possible to construct more than one reasonable estimator. Let α represent the true value of a parameter to be estimated; α is a vector α if there is more than one parameter. Then if $\widehat{\alpha}$ is an estimator for α , desirable properties for $\widehat{\alpha}$ are: (a) Unbiased; bias $b=E(\widehat{\alpha})-\alpha$, where the expectation value is taken over a hypothetical set of similar experiments in which $\widehat{\alpha}$ is constructed the same way. The bias may be due to statistical properties of the estimator or to systematic errors in the experiment. If we can estimate the average bias b we usually subtract it from $\widehat{\alpha}$ to obtain a new $\widehat{\alpha}' \equiv \widehat{\alpha} - b$. However, b may depend upon α or other unknowns, in which case we usually try to choose an estimator which minimizes its average size. (b) Minimum variance; the minimum possible value of $\mathrm{Var}(\widehat{\alpha})$ is given by the Rao-Cramér-Frechet bound:

$$Var_{\min} = \left[1 + \partial b/\partial \alpha\right]^{2} / I(\alpha) ;$$

$$I(\alpha) = E \left\{ \left[\frac{\partial}{\partial \alpha} \sum_{i=1}^{n} \ln f(x_{i}; \alpha) \right]^{2} \right\} .$$
(28.1)

(Compare with Eq. (28.6) below.) The sum is over all data and b is the bias, if any; the x_i are assumed independent and distributed as $f(x_i; \alpha)$, and the allowed range of x must not depend upon α . The ratio $\epsilon = \mathrm{Var_{min}}/\mathrm{Var}(\widehat{\alpha})$ is the efficiency. An efficient estimator (with $\epsilon = 1$) exists only for certain cases. The square root of the variance expresses the expected spread of $\widehat{\alpha}$ about its average value, as would be observed in a large number of repeats of the same measurement. (c) Minimum mean-squared error (mse); $\mathrm{mse} = E[(\widehat{\alpha} - \alpha)^2] = V(\widehat{\alpha}) + b^2$. The mse combines the error due to any bias quadratically with the variance, which expresses only the spread about $E(\widehat{\alpha})$, as distinct from α , the true value. (d) Robust; a robust estimator is not sensitive to errors in our assumptions, e.g., to departures from the assumed p.d.f. due to such factors as noise.

These criteria (and others) allow us to evaluate any procedure for obtaining $\widehat{\alpha}$. In many cases these criteria conflict. The bias, variance, and mse may depend on the unknown α . In this case the optimum prescription for $\widehat{\alpha}$ may depend on the range in which we assume α to lie.

Following are techniques in common use for obtaining estimators and their standard errors $\sigma(\widehat{\alpha}) = \sqrt{\mathrm{Var}(\widehat{\alpha})}$. When the conditions of the central limit theorem are satisfied, the interval $\widehat{\alpha} \pm \sigma(\widehat{\alpha})$ forms a 68.3% confidence interval. This is a random interval in that its endpoints depend upon the randomly sampled data; its meaning here will be taken to be that in 68.3% of all similar experiments the interval will include the true value α . One should be aware that in most practical cases the central limit theorem is only approximately satisfied and accordingly confidence intervals which depend on that are only approximate. Confidence intervals are discussed in Section 28.6 below.

28.2. Data with a common mean

Suppose we have a set of N independent measurements y_i assumed to be unbiased measurements of the same unknown quantity μ with a common, but unknown, variance σ^2 resulting from measurement error. Then

$$\widehat{\mu} = \frac{1}{N} \sum_{i=1}^{N} y_i = E(y)$$
(28.2)

$$\widehat{\sigma}^2 = \frac{1}{N-1} \sum_{i=1}^{N} (y_i - \widehat{\mu})^2 = \frac{N}{N-1} \left(E(y^2) - \widehat{\mu}^2 \right)$$
 (28.3)

are unbiased estimators of μ and σ^2 . The variance of $\widehat{\mu}$ is σ^2/N . If the common p.d.f. of the y_i is Gaussian, these statistics are independent. Then, for large N, the standard deviation of $\widehat{\sigma}$ (the "error of the error") is $\sigma/\sqrt{2N}$. If the y_i are Gaussian or N is large enough that the central limit theorem applies, then $\widehat{\mu}$ is an efficient estimator for μ . Otherwise $\widehat{\mu}$ is sometimes subject to large fluctuations, e.g., if the p.d.f. for y_i has long tails. In this case the median of the y_i may be a more robust estimator for μ , provided the median and mean are expected to lie at the same point in the p.d.f. for y. For Gaussian y, the median has asymptotic (large-N) efficiency $2/\pi \approx 0.64$. Student's t-distribution provides an example in which there are large tails. In this case, for large N the efficiency of the sample median relative to the sample mean is $(\infty, \infty, 1.62, 1.12, 0.96, 0.80, 0.64)$ for $(1, 2, 3, 4, 5, 8, \infty)$ degrees of freedom.

If σ^2 is known, $\widehat{\mu}$ as given in Eq. (28.2) is still the best estimator for μ ; if μ is known, substitute it for $\widehat{\mu}$ in Eq. (28.3) and replace N-1 by N, to obtain a somewhat better estimator $\widehat{\sigma}^2$.

If the y_i have different, known, variances σ_i^2 , then

$$\widehat{\mu} = \frac{1}{w} \sum_{i=1}^{N} w_i \ y_i \ , \tag{28.4}$$

is an unbiased estimator for μ with smaller variance than Eq. (28.2), where $w_i = 1/\sigma_i^2$ and $w = \sum w_i$. The standard deviation of $\widehat{\mu}$ is $1/\sqrt{w}$.

28.3. The method of maximum likelihood

28.3.1. General:

"From a theoretical point of view, the most important general method of estimation so far known is the *method of maximum likelihood*" [1]. We suppose that a set of independently measured quantities x_i came from a p.d.f. $f(x;\alpha)$, where α is an unknown set of parameters. The method of maximum likelihood consist of finding the set of values, $\widehat{\alpha}$, which maximizes the joint probability density for all the data, given by

$$\mathcal{L}(\alpha) = \prod_{i} f(x_i; \alpha) , \qquad (28.5)$$

where \mathscr{L} is called the likelihood. It is usually easier to work with $\ln \mathscr{L}$, and since both are maximized for the same set of α , it is sufficient to solve the *likelihood equation*

$$\frac{\partial \ln \mathcal{L}}{\partial \alpha_n} = 0 \ . \tag{28.6}$$

The solution is called the maximum likelihood estimate of α . The importance of the approach is shown by the following proposition, proved in Ref. 1:

If an efficient estimate $\hat{\alpha}$ of α exists, the likelihood equation will have a unique solution equal to $\hat{\alpha}$.

In evaluating \mathscr{L} , it is important that any normalization factors in the f's which involve α be included. However, we will only be interested in the maximum of \mathscr{L} and in ratios of \mathscr{L} at different α 's;

hence any multiplicative factors which do not involve the parameters we want to estimate may be dropped; this includes factors which depend on the data but not on α .

If the solution to Eq. (28.6) is at a maximum, $\partial \ln \mathcal{L}/\partial \alpha_n$ will have negative slope in its vicinity. In many practical problems, one often uses nonlinear algorithms for finding the maximum, and must be alert to various possibilities for error: (a) Eq. (28.6) may yield a minimum, therefore one must check the second derivative; (b) there may be more than one maximum—one must try to find the global maximum; (c) the global maximum may lie at a boundary of the physical region, in which case Eq. (28.6) will not find it.

If an unbiased, efficient estimator exists, this method will find it. If $\partial \ln \mathcal{L}/\partial \alpha_n$ is linear in the vicinity of the root, an efficient estimator is guaranteed; other efficient cases are discussed in the literature. For large data samples, the central limit theorem will usually assure this condition in some significant neighborhood of zero; hence the estimator is usually efficient in that case, provided certain conditions are met (e.g., that the solution does not lie on a boundary). In this case, in the neighborhood of the maximum $\ln \mathcal{L}$ is a downward-curving paraboloid and \mathcal{L} is proportional to a multivariate Gaussian.

The results of two or more experiments may be combined by forming the product of the \mathscr{L} 's, or the sum of the $\ln \mathscr{L}$'s.

Under a one-to-one change of parameters from α to $\beta = \beta(\alpha)$, the maximum likelihood estimate is simply $\beta(\widehat{\alpha})$, given the solution $\widehat{\alpha}$ for α . That is, the maximum likelihood solution for β is found by simple substitution of $\widehat{\alpha}$ into the transformation equation. It is possible that the new solution $\widehat{\beta}$ will be a biased solution for the true value of β even if $\widehat{\alpha}$ is not biased, and vice-versa. In the asymptotic limit (of large amounts of data) both $\widehat{\alpha}$ and $\widehat{\beta}$ will (usually) converge to unbiased solutions, but at different rates.

Except in special cases like the least-squares method, the value of the likelihood function at the solution does not necessarily tell us whether the final fit was a sensible description of the data or not. In special cases such as the one discussed in Sec. 28.3.3, one can define a quantity which approaches the χ^2 -distribution in the limit of a large number of counts in the experiment, but in general some other strategy must be used. For example, data generated by Monte Carlo simulations of the experiment can be analyzed by the same method. If the experimental likelihood is lower than that of some agreed-upon fraction of these results, one should question the appropriateness of the p.d.f. At the same time one can check for bias in the solution.

28.3.2. Error estimates:

The covariance matrix V may be estimated from

$$V_{nm} = \left(E \left[-\frac{\partial^2 \ln \mathcal{L}}{\partial \alpha_n \partial \alpha_m} \Big|_{\widehat{\Omega}} \right] \right)^{-1} . \tag{28.7}$$

If $\partial \ln \mathcal{L}/\partial \alpha_n$ is linear, the "expectation" operation in Eq. (28.7) has no effect because the second derivative of $\ln \mathcal{L}$ is constant. Otherwise, it may be approximated by taking the average of the quantity in square brackets over a range of α_n and α_m near the solution. For complex cases it may be more practical to evaluate s-standard-deviation errors from the contour

$$ln \mathcal{L}(\boldsymbol{\alpha}) = \ln \mathcal{L}_{\text{max}} - s^2/2 , \qquad (28.8)$$

where $\ln \mathscr{L}_{\max}$ is the value of $\ln \mathscr{L}$ at the solution point (compare with Eq. (28.32), below). The extreme limits of this contour parallel to the α_n axis give an approximate s-standard-deviation confidence interval in α_n . These intervals may not be symmetric and they may even consist of two or more disjoint intervals. This procedure gives one-standard-deviation errors in α_n equal to $\sqrt{V_{nn}}$ (not summed) of Eq. (28.7) if the estimator is efficient. If it is not efficient, the level of confidence implied by the value of s is only approximate.

28.3.3. Application to Poisson-distributed data:

In the case of Poisson-distributed data in a counting experiment, the unbinned maximum likelihood method (where the index i in Eq. (28.5) labels events) is preferred if the total number of events is very small. If there are enough events to justify binning them in a histogram, then one may alternatively maximize the likelihood function for the contents of the bins (so i labels bins). This is equivalent to minimizing [7]

$$\chi^{2} = \sum_{i} \left[2(N_{i}^{\text{th}} - N_{i}^{\text{obs}}) + 2N_{i}^{\text{obs}} \ln(N_{i}^{\text{obs}}/N_{i}^{\text{th}}) \right]. \tag{28.9}$$

where N_i^{obs} and N_i^{th} are the observed and theoretical (from f) contents of the ith bin. In bins where $N_i^{\text{obs}} = 0$, the second term is zero. This function asymptotically behaves like a classical χ^2 for purposes of point estimation, interval estimation, and goodness-of-fit. It also guarantees that the area under the fitted function f is equal to the sum of the histogram contents (as long as the overall normalization of f is effectively left unconstrained during the fit), which is not the case for χ^2 statistics based on a least-squares procedure with traditional weights.

28.4. Propagation of errors

Suppose that $F(x; \alpha)$ is some function of variable(s) x and the fitted parameters α , with a value \widehat{F} at $\widehat{\alpha}$. The variance matrix of the parameters is V_{mn} . To first order in $\alpha_m - \widehat{\alpha}_m$, F is given by

$$F = \hat{F} + \sum_{m} \frac{\partial F}{\partial \alpha_m} (\alpha_m - \hat{\alpha}_m) , \qquad (28.10)$$

and the variance of F about its estimator is given by

$$(\Delta F)^2 = E[(F - \hat{F})^2] = \sum_{mn} \frac{\partial F}{\partial \alpha_n} \frac{\partial F}{\partial \alpha_n} V_{mn} , \qquad (28.11)$$

evaluated at the x of interest. For different functions F_j and F_k , the covariance is

$$E[(F_j - \hat{F}_j)(F_k - \hat{F}_k)] = \sum_{mn} \frac{\partial F_j}{\partial \alpha_m} \frac{\partial F_k}{\partial \alpha_n} V_{mn} . \qquad (28.12)$$

If the first-order approximation is in serious error, the above results may be very approximate. \widehat{F} may be a biased estimator of F even if the $\widehat{\alpha}$ are unbiased estimators of α . Inclusion of higher-order terms or direct evaluation of F in the vicinity of $\widehat{\alpha}$ will help to reduce the bias.

28.5. Method of least squares

The method of least squares can be derived from the maximum likelihood theorem. We suppose a set of N measurements at points x_i . The ith measurement y_i is assumed to be chosen from a Gaussian distribution with mean $F(x_i; \boldsymbol{\alpha})$ and variance σ_i^2 . Then

$$\chi^2 = -2\ln\mathcal{L} + \text{constant} = \sum_{i=1}^{N} \frac{[y_i - F(x_i; \boldsymbol{\alpha})]^2}{\sigma_i^2} . \tag{28.13}$$

Finding the set of parameters α which maximizes $\mathcal L$ is the same as finding the set which minimizes χ^2 .

In many practical cases one further restricts the problem to the situation in which $F(x_i; \boldsymbol{\alpha})$ is a linear function of the α_m 's,

$$F(x_i; \boldsymbol{\alpha}) = \sum_{n} \alpha_n f_n(x) , \qquad (28.14)$$

where the f_n are k linearly independent functions (e.g., 1, x. x^2 , ..., or Legendre polynomials) which are single-valued over the allowed range of x. We require $k \leq N$, and at least k of the x_i must be distinct. We wish to estimate the linear coefficients α_n . Later we will discuss the nonlinear case.

If the point errors $\epsilon_i=y_i-F(x_i;\pmb{\alpha})$ are Gaussian, then the minimum χ^2 will be distributed as a χ^2 random variable with

n = N - k degrees of freedom. We can then evaluate the goodnessof-fit (confidence level) from Figs. 27.1 or 27.3, as per the earlier discussion. The confidence level expresses the probability that a worse fit would be obtained in a large number of similar experiments under the assumptions that: (a) the model $y = \sum \alpha_n f_n$ is correct and (b) the errors ϵ_i are Gaussian and unbiased with variance $\sigma_i^2.$ If this probability is larger than an agreed-upon value (0.001, 0.01, or 0.05 are common choices), the data are consistent with the assumptions; otherwise we may want to find improved assumptions. As for the converse, most people do not regard a model as being truly inconsistent unless the probability is as low as that corresponding to four or five standard deviations for a Gaussian $(6 \times 10^{-3} \text{ or } 6 \times 10^{-5})$; see Sec. 28.6.1). If the ϵ_i are not Gaussian, the method of least squares still gives an answer, but the goodness-of-fit test would have to be done using the correct distribution of the random variable which is still called " χ^2 ."

Finding the minimum of χ^2 in the linear case is straightforward:

$$-\frac{1}{2}\frac{\partial \chi^2}{\partial \alpha_m} = \sum_i f_m(x_i) \left(\frac{y_i - \sum_n \alpha_n f_n(x_i)}{\sigma_i^2} \right)$$
$$= \sum_i \frac{y_i f_m(x_i)}{\sigma_i^2} - \sum_n \alpha_n \sum_i \frac{f_n(x_i) f_m(x_i)}{\sigma_i^2} . \quad (28.15)$$

With the definitions

$$g_m = \sum_{i} y_i \ f_m(x_i) / \sigma_i^2 \tag{28.16}$$

and

$$V_{mn}^{-1} = \sum_{i} f_n(x_i) f_m(x_i) / \sigma_i^2 , \qquad (28.17)$$

the k-element column vector of solutions $\hat{\alpha}$, for which $\partial \chi^2/\partial \alpha_m = 0$ for all m, is given by

$$\widehat{\boldsymbol{\alpha}} = V \; \boldsymbol{g} \; . \tag{28.18}$$

With this notation, χ^2 for the special case of a linear fitting function (Eq. (28.14)) can be rewritten in the compact form

$$\chi^2 = \chi_{\min}^2 + (\boldsymbol{\alpha} - \widehat{\boldsymbol{\alpha}})^T V^{-1} (\boldsymbol{\alpha} - \widehat{\boldsymbol{\alpha}}) . \tag{28.19}$$

Nonindependent y_i 's

Eq. (28.13) is based on the assumption that the likelihood function is the product of independent Gaussian distributions. More generally, the measured y_i 's are not independent, and we must consider them as coming from a multivariate distribution with nondiagonal covariance matrix S, as described in Sec. 27.3.3. The generalization of Eq. (28.13) is

$$\chi^{2} = \sum_{jk} [y_{j} - F(x_{j}; \boldsymbol{\alpha})] S_{jk}^{-1} [y_{k} - F(x_{k}; \boldsymbol{\alpha})] .$$
 (28.20)

In the case of a fitting function that is linear in the parameters, one may differentiate χ^2 to find the generalization of Eq. (28.15), and with the extended definitions

$$g_m = \sum_{jk} y_j \ f_m(x_k) S_{jk}^{-1}$$

$$V_{mn}^{-1} = \sum_{jk} f_n(x_j) \ f_m(x_k) S_{jk}^{-1}$$
(28.21)

solve Eq. (28.18) for the estimators $\widehat{\alpha}$.

The problem of constructing the covariance matrix S is simplified by the fact that contributions to S (not to its inverse) are additive. For example, suppose that we have three variables, all of which have independent statistical errors. The first two also have a common error

resulting in a positive correlation, perhaps because a common baseline with its own statistical error (variance s^2) was subtracted from each. In addition, the second two have a common error (variance a^2), but this time the values are anticorrelated. This might happen, for example, if the sum of the two variables is a constant. Then

$$S = \begin{pmatrix} \sigma_1^2 & 0 & 0 \\ 0 & \sigma_2^2 & 0 \\ 0 & 0 & \sigma_3^2 \end{pmatrix} + \begin{pmatrix} s^2 & s^2 & 0 \\ s^2 & s^2 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & a^2 & -a^2 \\ 0 & -a^2 & a^2 \end{pmatrix} .$$
 (28.22)

If unequal amounts of the common baseline were subtracted from variables 1, 2, and 3—e.g., fractions f_1 , f_2 , and f_3 , then we would have

$$S = \begin{pmatrix} \sigma_1^2 & 0 & 0 \\ 0 & \sigma_2^2 & 0 \\ 0 & 0 & \sigma_3^2 \end{pmatrix} + \begin{pmatrix} f_1^2 s^2 & f_1 f_2 s^2 & f_1 f_3 s^2 \\ f_1 f_2 s^2 & f_2^2 s^2 & f_2 f_3 s^2 \\ f_1 f_3 s^2 & f_2 f_3 s^2 & f_2^2 s^2 \end{pmatrix} .$$
 (28.23)

While in general this "two-vector" representation is not possible, it underscores the procedure: Add zero-determinant correlation matrices to the matrix expressing the independent variation.

Care must be taken when fitting to correlated data, since off-diagonal contributions to χ^2 are not necessarily positive. It is even possible for all of the residuals to have the same sign.

Example: straight-line fit

For the case of a straight-line fit, $y(x) = \alpha_1 + \alpha_2 x$, one obtains, for independent measurements y_i , the following estimates of α_1 and α_2 ,

$$\widehat{\alpha}_1 = (g_1 \ V_{22}^{-1} - g_2 \ V_{12}^{-1})/D , \qquad (28.24)$$

$$\widehat{\alpha}_2 = (g_2 \ V_{11}^{-1} - g_1 \ V_{12}^{-1})/D \ , \tag{28.25}$$

where

$$(V_{11}^{-1}, V_{12}^{-1}, V_{22}^{-1}) = \sum (1, x_i, x_i^2) / \sigma_i^2,$$
 (28.26a)

$$(g_1, g_2) = \sum (1, x_i) y_i / \sigma_i^2 . \tag{28.26b}$$

respectively, and

$$D = V_{11}^{-1} V_{22}^{-1} - (V_{12}^{-1})^{2}. (28.27)$$

The covariance matrix of the fitted parameters is:

$$\begin{pmatrix} V_{11} & V_{12} \\ V_{12} & V_{22} \end{pmatrix} = \frac{1}{D} \begin{pmatrix} V_{22}^{-1} & -V_{12}^{-1} \\ -V_{12}^{-1} & V_{11}^{-1} \end{pmatrix} . \tag{28.28}$$

The estimated variance of an interpolated or extrapolated value of y at point x is:

$$(\hat{y} - y_{\text{true}})^2 \Big|_{\text{est}} = \frac{1}{V_{11}^{-1}} + \frac{V_{11}^{-1}}{D} \left(x - \frac{V_{12}^{-1}}{V_{11}^{-1}} \right)^2 .$$
 (28.29)

28.5.1. General comments:

If y is not linear in the fitting parameters α , the solution vector may have to be found by iteration. If we have a first guess α_0 , then we may expand to obtain

$$\frac{\partial \chi^2}{\partial \alpha} \bigg|_{\alpha} = \frac{\partial \chi^2}{\partial \alpha} \bigg|_{\alpha_0} + V_{\alpha_0}^{-1} \cdot (\alpha - \alpha_0) + \dots , \qquad (28.30)$$

where $\partial\chi^2/\partial\alpha$ is a vector whose mth component is $\partial\chi^2/\partial\alpha_m$, and $(V_{mn}^{-1})=\frac{1}{2}\partial^2\chi^2/\partial\alpha_m\partial\alpha_n$. (See Eqns. 28.7 and 28.17. When evaluated

at $\widehat{\alpha}$, V^{-1} is the inverse of the covariance matrix.) The next iteration toward $\widehat{\alpha}$ can be obtained by setting $\partial \chi^2/\partial \alpha_m|_{\alpha}=0$ and neglecting higher-order terms:

$$\alpha = \alpha_0 - V_{\alpha_0} \cdot \partial \chi^2 / \partial \alpha |_{\alpha_0} \tag{28.31}$$

If V is constant in the vicinity of the minimum, as it is when the model function is linear in the parameters, then χ^2 is parabolic as a function of α and Eq. (28.31) gives the solution immediately. Otherwise, further iteration is necessary. If the problem is highly nonlinear, considerable difficulty may be encountered. There may be secondary minima, and χ^2 may be decreasing at physical boundaries. Numerical methods have been devised to find such solutions without divergence [8,11]. In particular, the CERN program MINUIT [11] offers several iteration schemes for solving such problems.

Note that minimizing any function proportional to χ^2 (or maximizing any function proportional $\ln \mathcal{L}$) will result in the same parameter set $\hat{\alpha}$. Hence, for example, if the variances σ_j^2 are unknown but assumed equal and independent, one can still solve for $\hat{\alpha}$. One cannot, however, evaluate goodness-of-fit, and the covariance matrix is known only to within a constant multiplier. The scale can be estimated at least roughly from the size of χ^2 compared to its expected size.

Additional information can be extracted from the behavior of the (normalized) residuals, $r_j = (y_j - F(x_j; \alpha)/\sigma_j)$, which should themselves distribute normally with a mean of 0.

If the data covariance matrix S has been correctly evaluated (or, equivalently, the σ_j 's, if the data are independent), then the s-standard deviation limits on the parameters are given by a set α' such that

$$\chi^2(\alpha) = \chi^2_{\min} + s^2 \ . \tag{28.32}$$

This equation, a special case of 28.8, defines a contour in α -space; compare with the linear case in Eq. (28.19). It is often convenient for estimating errors in applications to nonlinear cases, where the matrix $V^{-1}|_{\alpha}$ may be a rapidly varying function of α . If the problem is highly nonlinear, such contours only approximately define the desired confidence regions which would have some given probability of covering the true value of α .

The method of least squares is sometimes used in cases where the distribution is not Gaussian or not known to be Gaussian. In such cases it can still be used, but it is then not a special case of the maximum-likelihood method, and the theorems having to do with that approach no longer apply. However, if (a) the distribution of $y_i - \sum \alpha_k f_k(x_i)$ has an expectation value of zero (unbiased) and (b) has a finite, known, fixed variance σ_i^2 (does not depend on α), then estimates of α obtained by minimizing χ^2 will be unbiased and have the smallest possible variance of all linear unbiased estimates (Gauss-Markov theorem). This statement is more general than the least-squares method as a special case of the maximum likelihood method in that the distributions do not have to be Gaussian, but more restrictive in that it applies only when the fitting function is linear in the α_k 's.

28.6. Errors and confidence intervals

We measure a mass, lifetime, or other physical quantity under the assumption that a "true answer" α exists. The conditions of the measurement introduce a random element, and our measurement (or combination of measurements) $\widehat{\alpha}_{\rm exp}$ samples a distribution with p.d.f. $f(\widehat{\alpha};\alpha)$. The unknown constant α appears as a parameter. We suppose that for every value of α we can find two values $\gamma_1(\alpha,\varepsilon)$ and $\gamma_2(\alpha,\varepsilon)$ such that repeated experiments would produce results in the interval $\gamma_1<\widehat{\alpha}<\gamma_2$ a fraction $1-\varepsilon$ of the time, where

$$1 - \varepsilon = \int_{\gamma_1}^{\gamma_2} f(\widehat{\alpha}; \alpha) \, d\widehat{\alpha} . \tag{28.33}$$

This situation is shown in Fig. 28.1 (ignore the "unphysical region" part of the graph for now), where the region between the curves $\gamma_1(\alpha,\varepsilon)$ and $\gamma_2(\alpha,\varepsilon)$ is indicated by the domain $D(\varepsilon)$. It can be argued that since the point $(\alpha_{\rm actual},\widehat{\alpha}_{\rm exp})$ belongs to D, then our statement that repeated experiments would produce values of $\widehat{\alpha}$ in the interval $\gamma_1<\widehat{\alpha}<\gamma_2$ is equivalent to the statement that the confidence interval $c_1<\alpha< c_2$ includes $\alpha_{\rm actual}$ with probability $1-\varepsilon$ [1,6]. (We will call ε the confidence coefficient.) In this "confidence interval" or frequentist approach, α is a parameter, not a statistical variable. Instead, c_1 and c_2 vary from experiment to experiment and are statistical variables. It is very different to say that a lifetime τ is to be found in the interval $\tau_0 \pm \sigma_\tau$ (which can vary from experiment to experiment) includes the actual, fixed, value of the lifetime with 68% probability.

The actual choice of γ_1 and γ_2 , such that $\int_{\gamma_1}^{\gamma_2} f(\widehat{\alpha}; \alpha) d\widehat{\alpha} = 1 - \varepsilon$, can be made in an infinite number of ways, but in practical situations there are usually additional criteria. For a Gaussian distribution, for example, choosing the limits symmetric about the mean minimizes the length of the interval. The area of the excluded tail on either side is then $\varepsilon/2$. For a Poisson distribution negative values cannot occur, so $\gamma(\widehat{\alpha},\alpha)$ (with $\widehat{\alpha}$ an integer and α the Poisson mean) might be taken as the curve below which ε of the area under the distribution lies. (In this case the curve really consists of discrete points, since $\widehat{\alpha}$ can have only discrete values.) For $\varepsilon=0.05$ the curve starts at $(\alpha,\widehat{\alpha})=(3.0,0)$. If in a given experiment no decays to a certain final state are seen, we might then conclude that $\alpha<3.0$ excludes the actual value of α with 95% probability. This statement can be converted to a similar statement about the branching fraction.

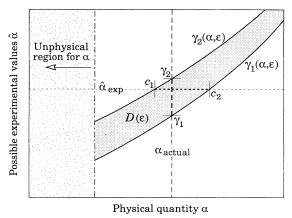

Figure 28.1: Confidence intervals for a single unknown parameter α . One might think of the p.d.f. $f(\widehat{\alpha};\alpha)$ as being plotted out of the paper as a function of $\widehat{\alpha}$ along each vertical line of constant α . The domain $D(\varepsilon)$ contains a fraction $1-\varepsilon$ of the area under each of these functions.

In Sec. 27 we discussed such confidence limits for a χ^2 distribution (where ε was called CL). Here we discuss confidence intervals for the Gaussian and Student's t-distribution, and confidence limits for the Poisson case. We then discuss the much more contentious situation in which the horizontal line at ordinate $\widehat{\alpha}$ in Fig. 28.1 enters $D(\varepsilon)$ at a boundary for unphysical values of α , so that at least c_1 is undefined—for example, if we find $\widehat{m}^2 = -30 \pm 50 \text{ eV}^2$.

Extensive tables and graphs were once used to find confidence intervals and limits, but by now their main function is to confirm that software is working. FORTRAN mathematical libraries (IMSL, NAG, CERNLIB) are readily available, and a wide range of distributions are available in personal computer spreadsheet applications such as Microsoft ® Excel [12]. Its built-in functions CHIDIST, NORMDIST, and TDIST (Student's t-distribution), along with "Solver," were used to produce or check the numbers given in this section.

Table 28.1: Area of the tails ε outside $\pm \delta$ from the mean of a Gaussian distribution.

ε (%)	δ	$\varepsilon~(\%)$	δ
31.73	1σ	20	1.28σ
4.55	2σ	10	1.64σ
0.27	3σ	5	1.96σ
6.3×10^{-3}	4σ	1	2.58σ
5.7×10^{-5}	5σ	0.1	3.29σ
2.0×10^{-7}	6σ	0.01	3.89σ

28.6.1. Gaussian errors:

If the data are such that the distribution of the estimator(s) satisfies the central limit theorem discussed in Sec. 27.3.3, the Gaussian distribution is the basis of the error analysis. If there is more than one parameter being estimated, the multivariate Gaussian is used. For the univariate case with known σ ,

$$1 - \varepsilon = \int_{\widehat{\mu} - \delta}^{\widehat{\mu} + \delta} f(x; \, \widehat{\mu}, \, \sigma^2) \, dx = \operatorname{erf}\left(\frac{\delta}{\sqrt{2} \, \sigma}\right)$$
 (28.34)

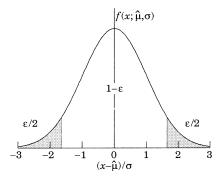

Figure 28.2: Illustration of a symetric 90% confidence interval (unshaded) for a measurement of a single quantity with Gaussian errors. Integrated probabilities, defined by ε , are as shown.

is the probability that the true value of μ will fall within $\pm \delta$ ($\delta > 0$) of the measured $\widehat{\mu}$. This interval will cover μ in a fraction $1 - \varepsilon$ of all similar measurements. Fig. 28.2 shows a $\delta = 1.64\sigma$ confidence interval unshaded. The choice $\delta = \sqrt{\mathrm{Var}(\widehat{\mu})} \equiv \sigma$ gives an interval called the standard error which has $1 - \varepsilon = 68.27\%$ if σ is known. Confidence coefficients ε for other frequently used choices of δ are given in Table 28.1. For other δ , find ε as the ordinate of Fig. 27.1 on the n=1 curve at $\chi^2=(\delta/\sigma)^2$. We can set a one-sided (upper or lower) limit by excluding above $\widehat{\mu}+\delta$ (or below $\widehat{\mu}-\delta$); ε 's for such limits are 1/2 the values in the table above.

We have increased confidence that the interval covers the true value as $1-\varepsilon$ increases, or χ^2 increases. We must be careful to distinguish this case from the other major use of Fig. 27.1, evaluation of goodness-of-fit (Sec. 28.5.0). In that case we have increased confidence in the fit as χ^2 decreases. In an attempt to reduce possible confusion in this discussion, we will use the ε notation (which corresponds to notation used in hypothesis testing [4]) when discussing confidence intervals and CL notation when discussing goodness-of-fit. Elsewhere in this *Review*, where the confusion between fit confidence level and interval (usually an upper or lower limit) confidence level does not arise, we follow the common practice of using "CL" to refer to the confidence level of the interval. This CL is understood to represent $1-\varepsilon$.

If the variance σ^2 of the estimator is not known, but must be estimated from the data, then we need to incorporate the error in $\widehat{\sigma}$ into our confidence interval using Student's t distribution. If we have

N data points with which we estimate k parameters, the Gaussian approximation is adequate for $N-k\gg 1$. Otherwise replace δ by a factor $T\widehat{\sigma}$, T being defined by

$$1 - \varepsilon = \int_{-T}^{T} f(t; N - k) dt , \qquad (28.35)$$

where f for the Student's t-distribution is defined in Table 27.1. T is tabulated in Ref. 13 and in Table 28.2.

Table 28.2: t limits containing $1 - \varepsilon$ of the area of Student's t-distribution f(t; N - k).

		ě	ε (%)			
$\overline{N-k}$	31.73	10.00	5.00	4.55	1.00	0.27
1	1.84	6.31	12.71	13.97	63.66	235.8
2	1.32	2.92	4.30	4.53	9.92	19.21
3	1.20	2.35	3.18	3.31	5.84	9.22
4	1.14	2.13	2.78	2.87	4.60	6.62
5	1.11	2.01	2.57	2.65	4.03	5.51
10	1.05	1.81	2.23	2.28	3.17	3.96
20	1.03	1.72	2.09	2.13	2.85	3.42
∞	1.00	1.64	1.96	2.00	2.58	3.00

For multivariate α we must consider pairwise correlations. Assuming a multivariate Gaussian, Eq. (27.22), and subsequent discussion the standard error ellipse for the pair $(\widehat{\alpha}_m, \widehat{\alpha}_n)$ may be drawn as in Fig. 28.3.

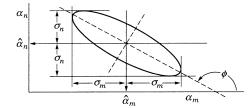

Figure 28.3: Standard error ellipse for the estimators $\widehat{\alpha}_m$ and $\widehat{\alpha}_n$. In this case the correlation is negative.

The minimum χ^2 or maximum likelihood solution is at $(\widehat{\alpha}_m, \widehat{\alpha}_n)$. The standard errors σ_m and σ_n are defined as shown, where the cllipse is at a constant value of $\chi^2 = \chi^2_{\min} + 1$ or $\ln \mathcal{L} = \ln \mathcal{L}_{\max} - 1/2$. The angle of the major axis of the cllipse is given by

$$\tan 2\phi = \frac{2\rho_{mn} \ \sigma_m \ \sigma_n}{\sigma_m^2 - \sigma_n^2} \ . \tag{28.36}$$

For non-Gaussian or nonlinear cases, one may construct an analogous contour from the same χ^2 or $\ln \mathscr{L}$ relations. Any other parameters $\widehat{\alpha}_\ell, \ell \neq m, n$ must be allowed freely to find their optimum values for every trial point.

For any unbiased procedure (e.g., least squares or maximum likelihood) being used to estimate k parameters α_i , $i=1,\ldots,k$, the probability $1-\varepsilon$ that the true values of all k lie within the s-standard deviation ellipsoid may be found from Fig. 27.1. Read the ordinate as ε ; the correct value of ε occurs on the n=k curve at $\chi^2=s^2$. For example, for k=2, the probability that the true values of α_1 and α_2 simultaneously lie within the one-standard-deviation error ellipse (s=1), centered on $\widehat{\alpha}_1$ and $\widehat{\alpha}_2$, is 39%. This probability only assumes Gaussian errors, unbiased estimators, and that the model describing the data in terms of the α_i is correct.

28.6.2. Poisson processes—upper limits:

Because the outcome of a Poisson process is an integral number of events, n_0 , it is usually not possible to set confidence intervals for the true Poisson parameter μ at a certain exact ε . For large n_0 an approximate interval can be set using the Gaussian approximation, in our section on Probability, Sec. 27.3.2, and the techniques of Sec. 28.6.1.

For small n_0 we can define an upper limit N for μ as being that value of μ such that it would be at least $1-\varepsilon$ (e.g., 90% or 95%) probable that a random observation of n would then lie above the observed n_0 . Thus

$$1 - \varepsilon = \sum_{n=n_0+1}^{\infty} f(n; N) ; \qquad \varepsilon = \sum_{n=0}^{n_0} f(n; N) .$$
 (28.37)

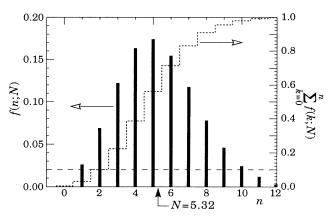

Figure 28.4: Illustration of Eq. (28.37) Poisson probabilities for an assumed mean of N. With an observed count $n_0=2$, N=5.32 as shown gives summed probability $\varepsilon=10\%$. The dotted summed probability curve (scale on right) has been displaced by -0.5 for clarity.

Fig. 28.4 illustrates the case with $n_0=2$ and $1-\varepsilon=90\%$, for which it may be shown that N=5.32. For any given n_0 and desired ε we can obtain N from the χ^2 Confidence Level figure because of a relation between the Poisson and the χ^2 distributions: read the ordinate as ε , find χ^2 on the curve for $n=2(n_0+1)$; then $N=\chi^2/2$. Some useful values are given in Table 28.3.

The meaning of these upper limits is that, for a given true μ , the probability is at least $1-\varepsilon$ that one will observe n_0 which will result in N which is $\geq \mu$. The probability for that to occur may be higher than $1-\varepsilon$; for example, if $\mu \leq 2.30$ a "90%" upper limit will actually exceed μ 100% of the time. Note from Eq. (28.37) that for $n_0 = 0$, $N = -\ln \varepsilon$

Table 28.3: Poisson upper limits N for n_0 observed events.

	$\varepsilon =$	$\varepsilon =$		$\varepsilon =$	$\varepsilon =$
n_0	10%	5%	n_0	10%	5%
0	2.30	3.00	6	10.53	11.84
1	3.89	4.74	7	11.77	13.15

4	7.99	9.15	10	15.41	16.96
5	9.27	10.51	11	16.60	18.21

28.6.3. Bounded physical region*:

The measurement of a physical constant α results in an estimator $\widehat{\alpha}$, together with some knowledge of experimental error and therefore knowledge of $f(\widehat{\alpha};\alpha)$, the parameterized p.d.f. that allows us to state the probability with which repeated experiments would produce results in a given range. It does not permit us to comment about α itself, which in this language is a constant, not a statistical variable. At the beginning of this section we introduced the confidence interval, or frequentist, approach to the problem, and were able to say that with a given probability the unknown parameter could be found between (statistical) limits c_1 and c_2 . But what if a physical boundary exists? Although polarization should be less than one and mass or its square should be greater than zero, experimental results do not always fall inside such a physical boundary because of statistical fluctuations.

However one might set a limit, there is little question about how to report and combine data [14]. A given experiment finds an unbiased estimator $\widehat{\alpha}=-5\pm 10$ for a physical constant (e.g. the square of the mass of a neutrino, in eV²). This value should be reported as the primary result. In case the true value is zero, for example, this "unphysical" result would not be unlikely. It can be combined with the results of other such experiments by forming the appropriately weighted average of unbiased results, including negative ones, to find an unbiased estimator which expresses our best knowledge of the parameter.

What if we wish to extend our concept of confidence limit to such a situation? The question of how to calculate an upper limit in the vicinity of a physical boundary is one of the most divisive in high-energy physics. We present two main approaches: The confidence interval, or frequentist, method, and the Bayesian method. "Classical method" is applied to one or the other by various writers, so we avoid the term.

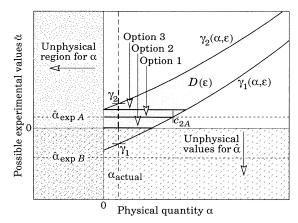

Figure 28.5: The situation near a physical boundary. In Fig. 28.1 the horizontal line for a given $\widehat{\alpha}_{\rm exp}$ crossed the domain $D(\varepsilon)$, bounded by $\gamma_1(\alpha, \epsilon)$ and $\gamma_2(\alpha, \epsilon)$ entirely in the physical region, entering at c_1 and leaving at c_2 . The limits γ_1 and γ_2 cannot be defined in a region where α is not defined, so the functions cannot be continued into the unphysical region. As a result c_1 (for experiment A) or c_1 and c_2 (for experiment B) cannot be defined. Options 1, 2, and 3 label the ways one might define confidence intervals, as described in the text.

1. The method of confidence intervals [1,15]. This is the approach described in the introduction, and requires little further explanation. It is presently the method in favor [1,6,14]. For a Gaussian distribution it gives the same result as the Bayesian approach with a flat prior distribution (see below) if the region containing α with the stated probability is far from an unphysical region, as in Fig. 28.1. Two cases in which this is untrue are shown in Fig. 28.5, where as a matter of convenience we assume that α must be positive. As before, we can define limits γ_1 and γ_2 for each value of the unknown parameter α , such that we can expect that a fraction $1-\varepsilon$ of repeated experiments to produce results between these limits. Since this can be done for

each value of α , the limits are described by the functions $\gamma_1(\alpha,\varepsilon)$ and $\gamma_2(\alpha,\varepsilon)$. However, these cannot be extended into a region in which α makes no sense. Experimental result $\widehat{\alpha}_{\exp A}$, indicated in Fig. 28.5, is positive, but if the true value is $\alpha_{\rm actual}$ a significant fraction of repetitions of the experiment would produce negative $\widehat{\alpha}$. In these cases there is no horizontal intercept c_1 , so without further assumptions we cannot make a statement about the region which would cover $\alpha_{\rm actual}$ in a given fraction of experiments. Experimental result $\widehat{\alpha}_{\exp B}$ presents a more serious problem, since it is so negative that there is no physical α for which the point $(\widehat{\alpha}, \alpha)$ lies in the domain $D(\varepsilon)$. The reason why the frequentist method gives no confidence interval is clear: This measured value of $\widehat{\alpha}$ would be unlikely no matter what the true value of α was.

There are several ad hoc ways to set confidence limits in such cases, although many frequentists would prefer to stop with the weighted average of unbiased results—if the outcome is exceedingly unlikely, one should look to the experiment, not to the statistics. The methods we list below all involve placing c_1 on the physical boundary, which in our example is at $\alpha = 0$.

- 1. If $\widehat{\alpha}_{\exp} > \gamma_1(0, \varepsilon)$, as in Experiment A, c_2 is defined. Use it for the upper limit, whether or not $\widehat{\alpha}_{\exp} > 0$.
- 2. If $\widehat{\alpha}_{\exp} < 0$, as in Experiment B, use the c_2 corresponding to $\widehat{\alpha}_{\exp} = 0$.
- 3. If c_1 is not defined, "lift up" $\hat{\alpha}$ to $\gamma_2(0,\varepsilon)$, where $c_1=0$. Use the corresponding c_2 as the upper limit.

These three options are shown in in Fig. 28.5; note that there are regions where more than one of them can be used, with different results. The third option is certainly the most conservative. For Gaussian $f(\widehat{\alpha};\alpha)$ the upper limit c_2 is a one-sided Gaussian confidence limit; read the tables for a 90% two-sided limit to obtain 95% one-sided limit. Alternatively, read the intercepts of the dotted lines in Fig. 28.7. (The horizontal axis is incorrectly labeled for this application.)

2. The Bayesian approach [3]. This is the approach favored in the older literature, and has (unfortunately and incorrectly) been referred to as the "PDG method" in certain papers. To begin with, it is argued that while α is not a statistical variable, our knowledge of α is less than complete, and it is fair to describe our uncertainty by treating α as a statistical variable. The parameterized p.d.f. $f(\widehat{\alpha}; \alpha)$ is replaced by the conditional p.d.f. $f(\widehat{\alpha}|\alpha)$. The confidence limit question can then be rephrased: Our measurements provide $f(\widehat{\alpha}|\alpha)$, that is, information about $\widehat{\alpha}$ for a fixed and unknown value of α , while we really want to know $g(\alpha|\widehat{\alpha})$, which tells us that, given our measurement $\widehat{\alpha}$, the "true answer" α lies between α and $\alpha+d\alpha$ with probability $g(\alpha|\widehat{\alpha}) d\alpha$. The connection is provided by Bayes' theorem (Eq. (27.7):

$$g(\alpha|\widehat{\alpha}) = \frac{f(\widehat{\alpha}|\alpha) \pi(\alpha)}{\int f(\widehat{\alpha}|\alpha) \pi(\alpha) d\alpha}.$$
 (28.38)

Here $\pi(\alpha)$ represents our "advance knowledge" of the value of α . In the usual case we claim no prior knowledge, so that before the experiment all physically reasonable values of α are equally probable: $\pi(\alpha)$ is a constant over the region of interest and zero in the unphysical region. This assumption leads to the conclusion that

$$g(\alpha|\widehat{\alpha}) = \begin{cases} f(\widehat{\alpha}|\alpha) / \int f(\widehat{\alpha}|\alpha) \, d\alpha & \text{if } \alpha \text{ is in the physical region;} \\ 0 & \text{otherwise;} \end{cases}$$

where this time the integral is over the physical region. In Fig. 28.6 we assume that an ensemble of experiments would produce values for $\hat{\alpha}$ which distribute as shown, with a significant probability of obtaining results with unphysical values. With our assumed step function $\pi(\alpha)$, the effect of Eq. (28.38) or (28.39) is to replace this distribution with the function shown by the shaded region, except that it is renormalized to unit area. By stating our confidence at the 90% level that α lies below the beginning of the dark shaded region, we mean that 90% of the area in the physical region is in the light shaded region.

In most cases of interest in this Review, $\hat{\alpha}$ is assumed to be a random value from a Gaussian distribution. Application of the procedure sketched in Fig. 28.6 then leads to the family of curves shown in Fig. 28.7. The confidence limit set by this method is always greater than the [one-sided] confidence interval set without the restriction of an unphysical region, and approaches it from above as the tail in the

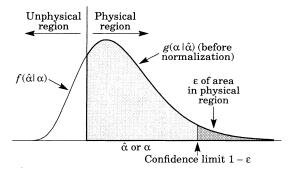

Figure 28.6: An example of a bounded physical region, in which a measurement $\widehat{\alpha}$ can fall in an unphysical region with significant probability. If we assume that α , the quantity we are trying to measure, cannot lie in the unphysical region (0 probability) but can lie anywhere in the physical region ("no prior knowledge"), then Bayes' theorem says that our new knowledge of the distribution of α , given our measurement $\widehat{\alpha}$, is given by the shaded function after appropriate renormalization.

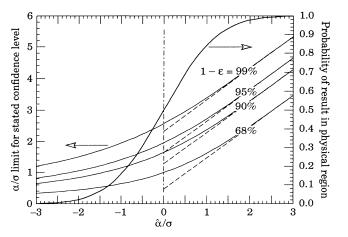

Figure 28.7: Application of the Bayesian scheme shown in Fig. 28.6 to the case of Gaussian $f(\widehat{\alpha}|\alpha)$. For example, if our measurement $\widehat{\alpha}$ is 1.0 standard deviations negative, then we conclude that $\alpha < 1.15\sigma$ with 90% probability—however, there is only a 31% probability that an experimental result as low as this would occur. Note that these are upper limits, so that the asymptote for large $\widehat{\alpha}/\sigma$ corresponds to a one-sided confidence interval, e.g., the asymptote for a 95% confidence level is $\alpha < \widehat{\alpha} + 1.64\sigma$, corresponding to a 90% confidence interval for a two-sided distribution. The dashed lines show the frequentist limit; if Option 3 is used, these are extended horizontally to the right for negative $\widehat{\alpha}/\sigma$.

unphysical region becomes unimportant. It is also greater than any of the limits shown in Fig. 28.5. With a small modification (exclusion of that portion of the negative tail inside the physical region in the confidence interval definition), it smoothly approaches the usual two-sided confidence interval for Gaussian distributions.

Even so, it is not a valid confidence limit. If it were, the interval would include the true value of α with exactly $1-\varepsilon$ probability no matter what the true value was. If the true answer is zero, our procedure, by guaranteeing a limit greater than zero for any experiment, also guarantees that the confidence interval for any ε includes $\alpha_{\rm actual}$ with 100% probability. Only as α increases does the probability decrease toward the α -independent Gaussian result.

The error function corresponding to the right axis of Fig. 28.7 shows the probability that $\widehat{\alpha}/\sigma$ at or below the given value should occur. If the experimental value is exceeding improbable, then the

formal confidence limit obtained by this or any other method means very little.

What about the arbitrariness of $\pi(\alpha)$? If the square of the neutrino mass is measured $(\alpha = m_{\nu}^2)$, then should we not take the prior knowledge distribution as proportional to $\sqrt{\alpha}$?[†] There are other attractive options. Jeffreys points out that if $\pi(\alpha) d\alpha = d\alpha/\alpha$, then the distributions for α and α^n are proportional [16], but there are practical difficulties with this approach. Lynch has investigated prior distributions that are constant in α , α^2 , and $\sqrt{\alpha}$ in the context of Gaussian $f(\widehat{\alpha}|\alpha)$, and has observed that assuming a prior distribution that is flat in α gives results that are much more satisfactory than one gets from the others [17]: All three methods have the property that the probability that the calculated limit contains the correct answer is 100\% when $\alpha = 0$ and approaches the proper value when $\alpha \gg \sigma$, but the approach to the proper value as α increases is much faster when the prior distribution is taken to be flat in α . In this case the approach is also monotonic, giving it the "conservative" property that for no value of α will the method produce a limit that has a probability of being correct that is less than the stated confidence limit. Although there is nothing unique about the limit calculated with a constant $\pi(\alpha)$, it has desirable features and no obvious replacement.

Summary: If there is a significant probability of obtaining an estimator corresponding to an unphysical value for a parameter, there is no universally accepted way way to make a statement of the sort " α is less that c_2 with probability $1-\varepsilon$." A variety of upper limits can be defined, but no method is entirely satisfactory. The Bayesian method with a flat prior distribution gives a reasonable upper limit which combines everything we know about the unknown quantity α into a physically reasonable value, but it does not give a complete summary of the information contained in the experiment.

28.6.4. Poisson processes with background [18]:

If we observe n_0 events in a Poisson process which has two components, signal and background, estimating a limit on the signal is more complicated. Let μ_S be the unknown mean (the Poisson parameter) for the signal and μ_B be the mean for the sum of all backgrounds. Assume μ_B is known with negligible error; however we don't know n_B , the actual number of events resulting from the background. We do know that $n_B \leq n_0$. If $\mu_B + \mu_S$ is large, the Gaussian approximation to the Poisson distribution (see Sec. 27.3.2) is usually adequate, and one can define confidence intervals or limits as above, assuming $\hat{n}_B \approx \mu_B$ and therefore $\hat{\mu}_S = n_0 - \mu_B$ with variance equal to n_0 (larger than $\hat{\mu}_S$ to allow for the error in \hat{n}_B).

Otherwise an upper limit can be defined by extension of the argument of the preceding section. Let N be the desired upper limit on μ_S with confidence coefficient ε . Set N to be that value of μ_S such that any random repeat of the current experiment with $\mu_S = N$ and the same μ_B would observe *more* than n_0 events in total and would have $n_B \leq n_0$, all with probability $1 - \varepsilon$. For any assumed N and μ_B we can calculate this probability:

$$1 - \varepsilon = 1 - \frac{e^{-(\mu_B + N)} \sum_{n=0}^{n_0} \frac{(\mu_B + N)^n}{n!}}{e^{-\mu_B} \sum_{n=0}^{n_0} \frac{\mu_B^n}{n!}}.$$
 (28.40)

We adjust N to obtain a desired ε . For $\mu_B=0$ this converges to Eq. (28.37). As in that case (see the last paragraph of Section 28.6.2) this gives a conservative upper limit in that for any given true μ_S we get a true probability $\geq 1-\varepsilon$ that $N\geq \mu_S$, averaged over a large set of identically performed experiments. For $\varepsilon=0.10$, Fig. 28.8 shows N as a function of n_0 and μ_B .

Averaging of experiments and other comparisons require that n_0 and μ_B be quoted and the technique used for upper limit extraction be given.

If $\mu_B \gg n_0$ the experimenter should question the probability of observing n_B as that n_0 . If this is very small the background, μ_B , may not have been calculated properly and the upper limit for μ_S obtained under those assumptions may be too low. For example, in

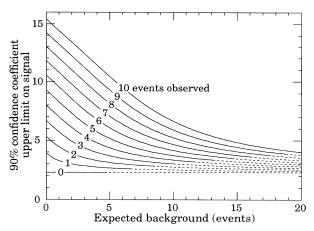

Figure 28.8: 90% confidence coefficient upper limit on the number of signal events as a function of the expected number of background events. For example, if the expected background is 8 events and 5 events are observed, then the signal is 4.0 (approximately) or less with 90% confidence. Dashed portions indicate regions where it is to be expected that the number observed would exceed the number actually observed \geq 99% of the time, even in the complete absence of signal.

Fig. 28.8, the dashed portions of the curves lie in the region where n_0 is expected to exceed the observed value 99% of the time (or more), even in the complete absence of signal. In these regions one should be cautious about accepting the results of the measurement.

As in the Gaussian case (Sec. 28.6.3), whenever $n_0 < \mu_B$ some experimenters may prefer to use N calculated as if $n_0 \approx \mu_B$ rather than the smaller value obtained from the observed n_0 .

28.7. Propagation of errors

Suppose we have a set of N random variables y_i which may be direct measurements or derived estimators $\widehat{\alpha}$, and we have a covariance matrix V(y) for these. We can make a transformation to a different set of variables $f_n \equiv f_n(y), \ j=1,\ldots,M \ (M\leq N)$ and obtain best estimates for the f_n from

$$\widehat{f}_n \approx f_n(\widehat{y}) + \frac{1}{2} \sum_{k,n}^{N} V_{kn}(\widehat{y}) \left[\frac{\partial^2 f_n}{\partial y_k \partial y_n} \right]_{\widehat{y}}$$
 (28.41)

with covariance matrix

$$V_{ij}(\hat{f}) \approx \sum_{n,m} \frac{\partial f_i}{\partial y_n} \Big|_{\widehat{y}} \left. \frac{\partial f_j}{\partial y_m} \Big|_{\widehat{y}} V_{nm}(\widehat{y}) \right.$$
 (28.42)

For a single-valued function f of a single measurement y with variance σ^2 (i.e., M=1,N=1), this becomes

$$\widehat{f} \approx f(\widehat{y}) + \frac{1}{2}\sigma^2 f''(\widehat{y})$$

$$V(\widehat{f}) \approx \sigma^2 [f'(\widehat{y})]^2 ,$$
(28.43)

where the primes denote differentiation with respect to y, evaluated at $\widehat{y}.$

These approximations are based on a Taylor expansion of f about the true value of y. If f is approximately linear in y over a range of roughly $\widehat{y}_i \pm \sigma(y_i)$, the approximation is good and the second-order terms in (28.41) and (28.43) can be neglected. This is what is usually done. However, if linearity is badly violated (e.g., $f \propto 1/y$ and \widehat{y} is no more than a few σ from zero), it should be recognized that propagation of errors will give very approximate results. In such cases $\widehat{f} \approx f(\widehat{y})$ may be a biased estimator for f even if \widehat{y} is unbiased for y, and the second-order terms in (28.41) and (28.43) will help to reduce that bias.

*In addition to the references cited, communications with R.D. Cousins, F. James, G. Lynch, and B. Roe have been invaluable in formulating this section.

[†]There is an additional problem: Even if we set a confidence limit on m_{ν}^2 by some particular recipe, it translates into a different confidence limit on $\sqrt{m_{\nu}^2}$ except when a Bayesian procedure with Jeffreys' $\pi(\alpha) \propto 1/\alpha$ prior distribution is used.

29. MONTE CARLO TECHNIQUES

Revised July 1995 by S. Youssef.

Monte Carlo techniques are often the only practical way to evaluate difficult integrals or to sample random variables governed by complicated probability density functions. Here we describe an assortment of methods for sampling some commonly occurring probability density functions.

29.1. Sampling the uniform distribution

Most Monte Carlo sampling or integration techniques assume a "random number generator" which generates uniform statistically independent values on the half open interval [0, 1). Although such a generator is, strictly speaking, impossible on a finite digital computer, generators are nevertheless available which pass extensive batteries of tests for statistical independence and which have periods which are so long that, for practical purposes, values from these generators can be considered to be uniform and statistically independent. In particular, the lagged-Fibonacci based generator introduced by Marsaglia, Zaman, and Tsang [1] is efficient, has a period of approximately 10⁴³, produces identical sequences on a wide variety of computers and, passes the extensive "DIEHARD" battery of tests [2]. Many commonly available congruential generators fail these tests and often have sequences (typically with periods less than 2³²) which can be easily exhausted on modern computers and should therefore be avoided [3].

29.2. Inverse transform method

If the desired probability density function is f(x) on the range $-\infty < x < \infty$, its cumulative distribution function (expressing the probability that $x \le a$) is given by Eq. (27.1). If a is chosen with probability density f(a), then the integrated probability up to point a, F(a), is itself a random variable which will occur with uniform probability density on [0,1]. If x can take on any value, and ignoring the endpoints, we can then find a unique x chosen from the p.d.f. f(s) for a given u if we set

$$u = F(x) , (29.1)$$

provided we can find an inverse of F, defined by

$$x = F^{-1}(u) (29.2)$$

This method is shown in Fig. 29.1a.

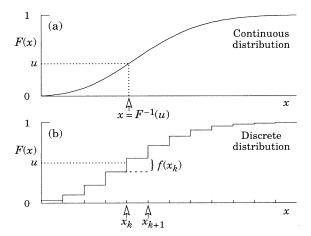

Figure 29.1: Use of a random number u chosen from a uniform distribution (0,1) to find a random number x from a distribution with cumulative distribution function F(x).

For a discrete distribution, F(x) will have a discontinuous jump of size $f(x_k)$ at each allowed $x_k, k = 1, 2, \cdots$. Choose u from a uniform distribution on (0,1) as before. Find x_k such that

$$F(x_{k-1}) < u \le F(x_k) \equiv \text{Prob}(x \le x_k) = \sum_{i=1}^k f(x_i);$$
 (29.3)

then x_k is the value we seek (note: $F(x_0) \equiv 0$). This algorithm is illustrated in Fig. 29.1b.

29.3. Acceptance-rejection method (Von Neumann)

Very commonly an analytic form for F(x) is unknown or too complex to work with, so that obtaining an inverse as in Eq. (29.2) is impractical. We suppose that for any given value of x the probability density function f(x) can be computed and further that enough is known about f(x) that we can enclose it entirely inside a shape which is C times an easily generated distribution h(x) as illustrated in Fig. 29.2.

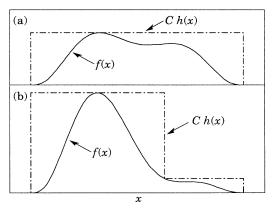

Figure 29.2: Illustration of the acceptance-rejection method. Random points are chosen inside the upper bounding figure, and rejected if the ordinate exceeds f(x). Lower figure illustrates importance sampling.

Frequently h(x) is uniform or is a normalized sum of uniform distributions. Note that both f(x) and h(x) must be normalized to unit area and therefore the proportionality constant C>1. To generate f(x), first generate a candidate x according to h(x). Calculate f(x) and the height of the envelope C h(x); generate u and test if $uCh(x) \leq f(x)$. If so, accept x; if not reject x and try again. If we regard x and uCh(x) as the abscissa and ordinate of a point in a two-dimensional plot, these points will populate the entire area Ch(x) in a smooth manner; then we accept those which fall under f(x). The efficiency is the ratio of areas, which must equal 1/C; therefore we must keep C as close as possible to 1.0. Therefore we try to choose Ch(x) to be as close to f(x) as convenience dictates, as in the lower part of Fig. 29.2. This practice is called importance sampling, because we generate more trial values of x in the region where f(x) is most important.

29.4. Algorithms

Algorithms for generating random numbers belonging to many different distributions are given by Press [4], Ahrens and Dieter [5], Rubinstein [6], Everett and Cashwell [7], Devroye [8], and Walck [9]. For many distributions alternative algorithms exist, varying in complexity, speed, and accuracy. For time-critical applications, these algorithms may be coded in-line to remove the significant overhead often encountered in making function calls. Variables named "u" are assumed to be independent and uniform on (0,1).

In the examples given below, we use the notation for the variables and parameters given in Table 27.1.

29.4.1. Sine and cosine of random angle:

Generate u_1 and u_2 . Then $v_1 = 2u_1 - 1$ is uniform on (-1,1), and $v_2 = u_2$ is uniform on (0,1). Calculate $r^2 = v_1^2 + v_2^2$. If $r^2 > 1$, start over. Otherwise, the sine (S) and cosine (C) of a random angle are given by

$$S = 2v_1v_2/r^2$$
 and $C = (v_1^2 - v_2^2)/r^2$. (29.4)

29.4.2. Gaussian distribution:

If u_1 and u_2 are uniform on (0,1), then

$$z_1 = \sin 2\pi u_1 \sqrt{-2 \ln u_2}$$
 and $z_2 = \cos 2\pi u_1 \sqrt{-2 \ln u_2}$ (29.5)

are independent and Gaussian distributed with mean 0 and $\sigma = 1$.

There are many faster variants of this basic algorithm. For example, construct $v_1=2u_1-1$ and $v_2=2u_2-1$, which are uniform on (-1,1). Calculate $r^2=v_1^2+v_2^2$, and if $r^2>1$ start over. If $r^2<1$, it is uniform on (0,1). Then

$$z_1 = v_1 \sqrt{\frac{-2 \ln r^2}{r^2}}$$
 and $z_2 = v_2 \sqrt{\frac{-2 \ln r^2}{r^2}}$ (29.6)

are independent numbers chosen from a normal distribution with mean 0 and variance 1. $z_i' = \mu + \sigma z_i$ distributes with mean μ and variance σ^2 .

For a multivariate Gaussian, see the algorithm in Ref. 10.

29.4.3. $\chi^2(n)$ distribution:

For n even, generate n/2 uniform numbers u_i ; then

$$y = -2 \ln \left(\prod_{i=1}^{n/2} u_i \right)$$
 is $\chi^2(n)$. (29.7)

For n odd, generate (n-1)/2 uniform numbers u_i and one Gaussian z as in Sec. 29.4.2; then

$$y = -2 \ln \left(\prod_{i=1}^{(n-1)/2} u_i \right) + z^2 \text{ is } \chi^2(n) .$$
 (29.8)

For $n \gtrsim 30$ the much faster Gaussian approximation for the χ^2 may be preferable: generate z as in Sec. 29.4.2 and use $y = \left[z + \sqrt{2n-1}\right]^2/2$; if $z < -\sqrt{2n-1}$ reject and start over.

${\bf 29.4.4.} \quad {\it Gamma~distribution}:$

All of the following algorithms are given for $\lambda=1.$ For $\lambda\neq 1,$ divide the resulting random number x by $\lambda.$

- If k = 1 (the exponential distribution), accept $x = -(\ln u)$.
- If 0 < k < 1, initialize with $v_1 = (e + k)/e$ (with e = 2.71828... being the natural log base). Generate u_1, u_2 . Define $v_2 = v_1u_1$.

Case 1: $v_2 \le 1$. Define $x = v_2^{1/k}$. If $u_2 \le e^{-x}$, accept x and step, else restart by generating new u_1, u_2 .

Case 2: $v_2 > 1$. Define $x = -\ln([v_1 - v_2]/k)$. If $u_2 \le x^{k-1}$, accept x and stop, else restart by generating new u_1 , u_2 . Note that, for k < 1, the probability density has a pole at x = 0, so that return values of zero due to underflow must be accepted or otherwise dealt with.

• Otherwise, if k > 1, initialize with c = 3k - 0.75. Generate u_1 and compute $v_1 = u_1(1 - u_1)$ and $v_2 = (u_1 - 0.5)\sqrt{c/v_1}$. If $x = k + v_2 - 1 \le 0$, go back and generate new u_1 ; otherwise generate u_2 and compute $v_3 = 64v_1^3u_2^2$. If $v_3 \le 1 - 2v_2^2/x$ or if $\ln v_3 \le 2\{[k-1]\ln[x/(k-1)] - v_2\}$, accept x and stop; otherwise go back and generate new u_1 .

29.4.5. Binomial distribution:

If $p \leq 1/2$, iterate until a successful choice is made: begin with k=1; compute $P_k=q^n$ [for $k\neq 1$ use $P_k\equiv f(r_k;n,p)$, and store P_k into B; generate u. If $u\leq B$ accept $r_k=k-1$ and stop; otherwise increment k by 1 and compute next P_k and add to B; generate a new u and repeat. If we arrive at k=n+1, stop and accept $r_{n+1}=n$. If p>1/2 it will be more efficient to generate r from f(r;n,q), i.e., with p and q interchanged, and then set $r_k=n-r$.

29.4.6. Poisson distribution:

Iterate until a successful choice is made: Begin with k=1 and set A=1 to start. Generate u. Replace A with uA; if now $A<\exp(-\mu)$, where μ is the Poisson parameter, accept $n_k=k-1$ and stop. Otherwise increment k by 1, generate a new u and repeat, always starting with the value of A left from the previous try. For large $\mu(\gtrsim 10)$ it may be satisfactory (and much faster) to approximate the Poisson distribution by a Gaussian distribution (see our Probability chapter, Sec. 27.3.3) and generate z from f(z;0,1); then accept $x=\max(0,[\mu+z\sqrt{\mu}+0.5])$ where $[\]$ signifies the greatest integer \le the expression.

29.4.7. Student's t distribution:

For n>0 degrees of freedom (n not necessarily integer), generate x from a Gaussian with mean 0 and $\sigma^2=1$ according to the method of 29.4.2. Next generate y, an independent gamma random variate with k=n/2 degrees of freedom. Then $z=x\sqrt{2n}/\sqrt{y}$ is distributed as a t with n degrees of freedom.

For the special case n=1, the Breit-Wigner distribution, generate u_1 and u_2 ; set $v_1=2u_1-1$ and $v_2=2u_2-1$. If $v_1^2+v_2^2\leq 1$ accept $z=v_1/v_2$ as a Breit-Wigner distribution with unit area, center at 0.0, and FWHM 2.0. Otherwise start over. For center M_0 and FWHM Γ , use $W=z\Gamma/2+M_0$.

30. MONTE CARLO PARTICLE NUMBERING SCHEME

Updated May 1996 by G.R. Lynch and T.G. Trippe.

• NOTE: We have received a proposal for a significant revision to our numbering scheme. The revision would include numbering for particles expected in the quark model but not yet discovered and for hypothetical states such as supersymmetric particles. The proposal was developed by the QCD Monte Carlo Event Generators working group of a LEP2 Workshop in 1995 and conveyed to us by Ian Knowles and Torbjorn Sjöstrand [1]. Lynn Garren, who is responsible for the STDHEP standard [2] at Fermilab, is also involved. We will put this proposal on the Particle Data Group WWW page (http://pdg.lbl.gov/) in the near future to invite comment and to provide information on the status of its acceptance.

Most particle physics Monte Carlo and analysis systems use a numbering scheme to represent particles. The lack of standardization of such schemes inhibits interfacing different programs. The following table proposes a standard numbering scheme. Some of the properties of this scheme are:

- Quarks and leptons are ordered by family, and within the family, by isospin. This puts the u and d in the opposite order than is often used in other numbering schemes. In our scheme we call the highest numbered quark the heaviest quark.
- 2. For multiple quark systems (mesons, baryons, and diquarks), the rightmost digit is generally L=2J+1. (The K^0_S and K^0_L are exceptions.) Particles with J>4 have not been assigned numbers.
- 3. Mesons are represented by the form NML and baryons by NMKL, where N, M, and K are quark numbers.
- 4. For these systems the highest quark number (see quark list below) is usually on the left and the quarks are in decreasing order of quark number from left to right. One exception to this convention is the K_L^0 - K_S^0 pair. A second exception is for the Λ 's for which we invert the up and down quarks to distinguish the Λ from the Σ^0 .
- 5. The other exception to this quark-number order rule is for some N's and Δ's. For N's, the u and d quark are reversed for spins 3/2 and 7/2. For Δ's, they are reversed for spins 1/2 and 5/2. The quarks are in the normal decreasing order when I + J is odd.
- Mesons, and only mesons, have the third digit nonzero and the fourth digit zero. (We designate the rightmost digit as the first digit.)

- 7. Only baryons and diquarks have the fourth digit nonzero.
- 8. Only quarks and diquarks have the second digit equal to zero.
- 9. Particles have positive numbers; each antiparticle has the negative of its counterpart.
- 10. The particle-antiparticle convention is the one used by the Particle Data Group, so that the K^+ and B^+ are particles.
- 11. The above rules imply that for mesons (as opposed to antimesons), when the number of the leftmost (heaviest) quark is even, it is a quark, and when the number of the leftmost quark is odd, it is an antiquark.
- 12. The gluon has two numbers. Its official number is 21 to place it with the other gauge bosons. Its number is also 9 so that a glueball is specified as 99.
- 13. The fifth digit is used to differentiate different particles with the same quark content and spin.
- 14. Although isospin is not manifest in this scheme, the isospin of any hadron can be determined from the number. Mesons with 11L are isospin 1 and those with 22L are isospin 0. For nonstrange baryons, if the quarks are in the normal decreasing order, then I+J is odd, otherwise I+J is even. If a strange baryon does not have the normal decreasing quark order, it has I=0.

More details about the motivation behind, and properties of, this scheme can be found in Ref. 3. Although this scheme has the advantage that a particle's number has considerable physics content, it has the disadvantage that it is not compact. An algorithm that translates this scheme into a more compact scheme is needed for its implementation. Contact the Berkeley Particle Data Group for further information on such an algorithm.

A list of particle numbers follows.

31. CLEBSCH-GORDAN COEFFICIENTS, SPHERICAL HARMONICS, AND d FUNCTIONS

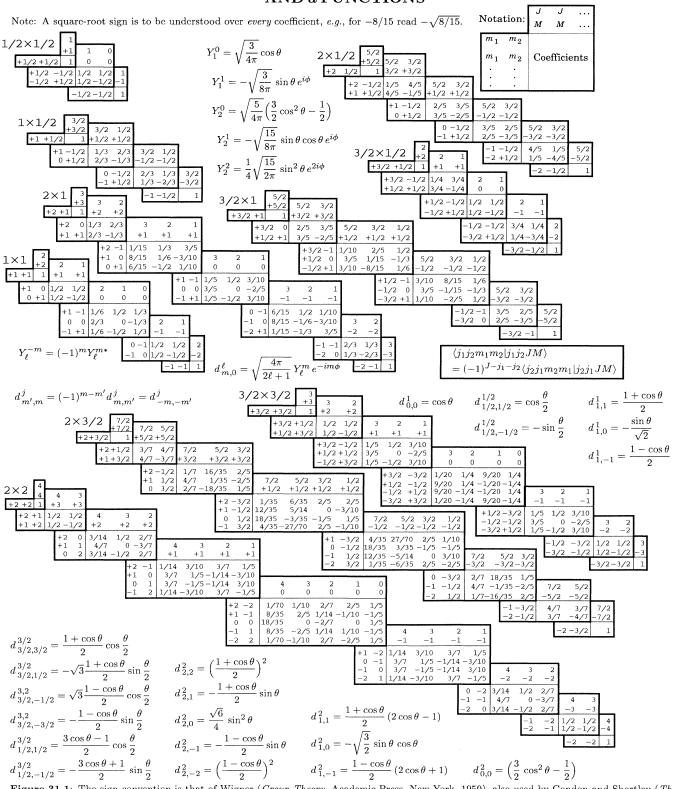

Figure 31.1: The sign convention is that of Wigner (*Group Theory*, Academic Press, New York, 1959), also used by Condon and Shortley (*The Theory of Atomic Spectra*, Cambridge Univ. Press, New York, 1953), Rose (*Elementary Theory of Angular Momentum*, Wiley, New York, 1957), and Cohen (*Tables of the Clebsch-Gordan Coefficients*, North American Rockwell Science Center, Thousand Oaks, Calif., 1974). The coefficients here have been calculated using computer programs written independently by Cohen and at LBNL.

32. SU(3) ISOSCALAR FACTORS AND REPRESENTATION MATRICES

The most commonly used SU(3) isoscalar factors, corresponding to the singlet, octet, and decuplet content of $8\otimes 8$ and $10\otimes 8$, are shown at the right. The notation uses particle names to identify the coefficients, so that the pattern of relative couplings may be seen at a glance. We illustrate the use of the coefficients below. See J.J de Swart, Rev. Mod. Phys. **35**, 916 (1963) for detailed explanations and phase conventions.

 $A \sqrt{\ }$ is to be understood over every integer in the matrices; the exponent 1/2 on each matrix is a reminder of this. For example, the $\Xi \to \Omega K$ element of the $10 \to 10 \otimes 8$ matrix is $-\sqrt{6}/\sqrt{24} = -1/2$.

Intramultiplet relative decay strengths may be read directly from the matrices. For example, in decuplet \to octet + octet decays, the ratio of $\Omega^* \to \varXi \overline{K}$ and $\Delta \to N\pi$ partial widths is, from the $10 \to 8 \times 8$ matrix,

$$\frac{\Gamma(\Omega^* \to \Xi \overline{K})}{\Gamma(\Delta \to N\pi)} = \frac{12}{6} \times \text{ (phase space factors)}.$$
 (32.1)

Including isospin Clebsch-Gordan coefficients, we obtain, e.g.,

$$\frac{\Gamma(\varOmega^{*-}\to \varXi^0 K^-)}{\Gamma(\varDelta^+\to p\,\pi^0)} = \frac{1/2}{2/3}\times \frac{12}{6}\times p.s.f. = \frac{3}{2}\times p.s.f. \tag{32.2}$$

Partial widths for $8 \to 8 \otimes 8$ involve a linear superposition of 8_1 (symmetric) and 8_2 (antisymmetric) couplings. For example,

$$\Gamma(\Xi^* \to \Xi \pi) \sim \left(-\sqrt{\frac{9}{20}} g_1 + \sqrt{\frac{3}{12}} g_2\right)^2$$
 (32.3)

The relations between g_1 and g_2 (with de Swart's normalization) and the standard D and F couplings that appear in the interaction Lagrangian,

$$\mathcal{L} = -\sqrt{2} D \operatorname{Tr} (\{\overline{B}, B\}M) + \sqrt{2} F \operatorname{Tr} ([\overline{B}, B]M) , \qquad (32.4)$$

where $[\overline{B}, B] \equiv \overline{B}B - B\overline{B}$ and $\{\overline{B}, B\} \equiv \overline{B}B + B\overline{B}$, are

$$D = \frac{\sqrt{30}}{40} g_1 , \qquad F = \frac{\sqrt{6}}{24} g_2 . \tag{32.5}$$

Thus, for example,

$$\Gamma(\Xi^* \to \Xi \pi) \sim (F - D)^2 \sim (1 - 2\alpha)^2$$
, (32.6)

where $\alpha \equiv D/(D+F)$.

The generators of SU(3) transformations, λ_a (a=1,8), are 3×3 matrices that obey the following commutation and anticommutation relationships:

$$[\lambda_a, \lambda_b] \equiv \lambda_a \lambda_b - \lambda_b \lambda_a = 2i f_{abc} \lambda_c \tag{32.7}$$

$$\{\lambda_a, \ \lambda_b\} \equiv \lambda_a \lambda_b + \lambda_b \lambda_a = \frac{4}{3} \delta_{ab} I + 2d_{abc} \lambda_c \ , \tag{32.8}$$

where I is the 3×3 identity matrix, and δ_{ab} is the Kronecker delta symbol. The f_{abc} are odd under the permutation of any pair of indices, while the d_{abc} are even. The nonzero values are

$$\mathbf{1} \to \mathbf{8} \otimes \mathbf{8}$$

$$(\Lambda) \rightarrow (N\overline{K} \Sigma \pi \Lambda \eta \Xi K) = \frac{1}{\sqrt{8}} (2 \ 3 \ -1 \ -2)^{1/2}$$

 $8_1 \rightarrow 8 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \rightarrow \begin{pmatrix} N\pi & N\eta & \Sigma K & \Lambda K \\ N\overline{K} & \Sigma\pi & \Lambda\pi & \Sigma\eta & \Xi K \\ N\overline{K} & \Sigma\pi & \Lambda\eta & \Xi K \\ \Sigma \overline{K} & \Lambda \overline{K} & \Xi\pi & \Xi\eta \end{pmatrix} = \frac{1}{\sqrt{20}} \begin{pmatrix} 9 & -1 & -9 & -1 \\ -6 & 0 & 4 & 4 & -6 \\ 2 & -12 & -4 & -2 \\ 9 & -1 & -9 & -1 \end{pmatrix}^{1/2}$$

 $8_2 \rightarrow 8 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \rightarrow \begin{pmatrix} N\pi & N\eta & \Sigma K & \Lambda K \\ N\overline{K} & \Sigma\pi & \Lambda\pi & \Sigma\eta & \Xi K \\ N\overline{K} & \Sigma\pi & \Lambda\eta & \Xi K \\ \Sigma\overline{K} & \Lambda\overline{K} & \Xi\pi & \Xi\eta \end{pmatrix} = \frac{1}{\sqrt{12}} \begin{pmatrix} 3 & 3 & 3 & -3 \\ 2 & 8 & 0 & 0 & -2 \\ 6 & 0 & 0 & 6 \\ 3 & 3 & 3 & -3 \end{pmatrix}^{1/2}$$

 $10 \rightarrow 8 \otimes 8$

$$\begin{pmatrix} \Delta \\ \Sigma \\ \Xi \\ \Omega \end{pmatrix} \rightarrow \begin{pmatrix} N\overline{K} \begin{array}{ccc} N\pi & \Sigma K \\ \Sigma \overline{K} \end{array} \begin{array}{ccc} N\pi & \Sigma K \\ \Sigma \overline{K} \end{array} \begin{array}{cccc} \Lambda \pi & \Sigma \eta & \Xi K \\ \Xi \overline{K} \end{array} \begin{array}{cccc} \Xi K \\ \Xi \overline{K} \end{array} \begin{array}{ccccc} = \frac{1}{\sqrt{12}} \begin{pmatrix} -6 & 6 & 6 & 6 \\ -2 & 2 & -3 & 3 & 2 \\ 3 & -3 & 3 & 3 & 12 \\ 12 & & & 12 & & 12 \end{pmatrix}^{1/2}$$

 $8 \rightarrow 10 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \rightarrow \begin{pmatrix} \Delta\pi & \Sigma K \\ \Sigma\overline{K} & \Sigma\pi & \Sigma\eta & \Xi K \\ \Sigma\overline{K} & \Xi\pi & \Xi\eta & \Omega K \end{pmatrix} \qquad = \frac{1}{\sqrt{15}} \begin{pmatrix} -12 & 3 \\ 8 & -2 & -3 & 2 \\ -9 & 6 \\ 3 & -3 & -3 & 6 \end{pmatrix}^{1/2}$$

 $10 \rightarrow 10 \otimes 8$

$$\begin{pmatrix} \Delta \\ \Sigma \\ \Xi \\ \Omega \end{pmatrix} \rightarrow \begin{pmatrix} \Delta \pi & \Delta \eta & \Sigma K \\ \Delta \overline{K} & \Sigma \pi & \Sigma \eta & \Xi K \\ \Sigma \overline{K} & \Xi \pi & \Xi \eta & \Omega K \\ \Xi \overline{K} & \Omega \eta \end{pmatrix} \qquad = \frac{1}{\sqrt{24}} \begin{pmatrix} 15 & 3 & -6 \\ 8 & 8 & 0 & -8 \\ 12 & 3 & -3 & -6 \\ 12 & -12 \end{pmatrix}^{1/2}$$

abc	f_{abc}	\underline{abc}	d_{abc}	abc	d_{abc}
123	1	118	$1/\sqrt{3}$	355	1/2
147	1/2	146	1/2	366	-1/2
156	-1/2	157	1/2	377	-1/2
246	1/2	228	$1/\sqrt{3}$	448	$-1/(2\sqrt{3})$
257	1/2	247	-1/2	558	$-1/(2\sqrt{3})$
345	1/2	256	1/2	668	$-1/(2\sqrt{3})$
367	-1/2	338	$1/\sqrt{3}$	778	$-1/(2\sqrt{3})$
458	$\sqrt{3}/2$	344	1/2	888	$-1/\sqrt{3}$
678	$\sqrt{3}/2$				

The λ_a 's are

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \quad \lambda_5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix} \quad \lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

$$\lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix} \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

Equation (32.7) defines the Lie algebra of SU(3). A general d-dimensional representation is given by a set of $d \times d$ matrices satisfying Eq. (32.7) with the f_{abc} given above. Equation (32.8) is specific to the defining 3-dimensional representation.

33. SU(n) MULTIPLETS AND YOUNG DIAGRAMS

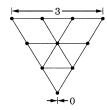

This note tells (1) how $\mathrm{SU}(n)$ particle multiplets are identified or labeled, (2) how to find the number of particles in a multiplet from its label, (3) how to draw the Young diagram for a multiplet, and (4) how to use Young diagrams to determine the overall multiplet structure of a composite system, such as a 3-quark or a meson-baryon system.

In much of the literature, the word "representation" is used where we use "multiplet," and "tableau" is used where we use "diagram."

33.1. Multiplet labels

An SU(n) multiplet is uniquely identified by a string of (n-1) nonnegative integers: $(\alpha, \beta, \gamma, \ldots)$. Any such set of integers specifies a multiplet. For an SU(2) multiplet such as an isospin multiplet, the single integer α is the number of steps from one end of the multiplet to the other (i.e., it is one fewer than the number of particles in the multiplet). In SU(3), the two integers α and β are the numbers of steps across the top and bottom levels of the multiplet diagram. Thus the labels for the SU(3) octet and decuplet

are (1,1) and (3,0). For larger n, the interpretation of the integers in terms of the geometry of the multiplets, which exist in an (n-1)-dimensional space, is not so readily apparent.

The label for the SU(n) singlet is $(0,0,\ldots,0)$. In a flavor SU(n), the n quarks together form a $(1,0,\ldots,0)$ multiplet, and the n antiquarks belong to a $(0,\ldots,0,1)$ multiplet. These two multiplets are conjugate to one another, which means their labels are related by $(\alpha,\beta,\ldots) \leftrightarrow (\ldots,\beta,\alpha)$.

33.2. Number of particles

The number of particles in a multiplet, $N=N(\alpha,\beta,\ldots)$, is given as follows (note the pattern of the equations).

In SU(2), $N = N(\alpha)$ is

$$N = \frac{(\alpha + 1)}{1} \tag{33.1}$$

In SU(3), $N = N(\alpha, \beta)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \ . \tag{33.2}$$

In SU(4), $N = N(\alpha, \beta, \gamma)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\gamma+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \cdot \frac{(\beta+\gamma+2)}{2} \cdot \frac{(\alpha+\beta+\gamma+3)}{3} . \tag{33.3}$$

Note that in Eq. (33.3) there is no factor with $(\alpha + \gamma + 2)$: only a consecutive sequence of the label integers appears in any factor. One more example should make the pattern clear for any SU(n). In SU(5), $N = N(\alpha, \beta, \gamma, \delta)$ is

$$\begin{split} N &= \frac{(\alpha + 1)}{1} \cdot \frac{(\beta + 1)}{1} \cdot \frac{(\gamma + 1)}{1} \cdot \frac{(\delta + 1)}{1} \cdot \frac{(\alpha + \beta + 2)}{2} \cdot \frac{(\beta + \gamma + 2)}{2} \\ &\times \frac{(\gamma + \delta + 2)}{2} \cdot \frac{(\alpha + \beta + \gamma + 3)}{3} \cdot \frac{(\beta + \gamma + \delta + 3)}{3} \cdot \frac{(\alpha + \beta + \gamma + \delta + 4)}{4} \ . \end{split} \tag{33.4}$$

From the symmetry of these equations, it is clear that multiplets that are conjugate to one another have the same number of particles, but so can other multiplets. For example, the SU(4) multiplets (3,0,0) and (1,1,0) each have 20 particles. Try the equations and see.

33.3. Young diagrams

A Young diagram consists of an array of boxes (or some other symbol) arranged in one or more left-justified rows, with each row being at least as long as the row beneath. The correspondence between a diagram and a multiplet label is: The top row juts out α boxes to the right past the end of the second row, the second row juts out β boxes to the right past the end of the third row, etc. A diagram in SU(n) has at most n rows. There can be any number of "completed" columns of n boxes buttressing the left of a diagram; these don't affect the label. Thus in SU(3) the diagrams

represent the multiplets (1,0), (0,1), (0,0), (1,1), and (3,0). In any SU(n), the quark multiplet is represented by a single box, the antiquark multiplet by a column of (n-1) boxes, and a singlet by a completed column of n boxes.

33.4. Coupling multiplets together

The following recipe tells how to find the multiplets that occur in coupling two multiplets together. To couple together more than two multiplets, first couple two, then couple a third with each of the multiplets obtained from the first two, etc.

First a definition: A sequence of the letters a,b,c,... is admissible if at any point in the sequence at least as many a's have occurred as b's, at least as many b's have occurred as c's, etc. Thus abcd and aabcb are admissible sequences and abb and acb are not. Now the recipe:

- (a) Draw the Young diagrams for the two multiplets, but in one of the diagrams replace the boxes in the first row with a's, the boxes in the second row with b's, etc. Thus, to couple two SU(3) octets (such as the π -meson octet and the baryon octet), we start with \square and
- $^{\rm a}_{\rm b}$ $^{\rm a}$. The unlettered diagram forms the upper left-hand corner of all the enlarged diagrams constructed below.
- (b) Add the a's from the lettered diagram to the right-hand ends of the rows of the unlettered diagram to form all possible legitimate Young diagrams that have no more than one a per column. In general, there will be several distinct diagrams, and all the a's appear in each diagram. At this stage, for the coupling of the two SU(3) octets, we have:

- (c) Use the b's to further enlarge the diagrams already obtained, subject to the same rules. Then throw away any diagram in which the full sequence of letters formed by reading right to left in the first row, then the second row, etc., is not admissible.
 - (d) Proceed as in (c) with the c's (if any), etc.

The final result of the coupling of the two SU(3) octets is:

Here only the diagrams with admissible sequences of a's and b's and with fewer than four rows (since n=3) have been kept. In terms of multiplet labels, the above may be written

$$(1,1) \otimes (1,1) = (2,2) \oplus (3,0) \oplus (0,3) \oplus (1,1) \oplus (1,1) \oplus (0,0)$$
.

In terms of numbers of particles, it may be written

$$\mathbf{8}\otimes\mathbf{8}=\mathbf{27}\oplus\mathbf{10}\oplus\overline{\mathbf{10}}\oplus\mathbf{8}\oplus\mathbf{8}\oplus\mathbf{1}$$
 .

The product of the numbers on the left here is equal to the sum on the right, a useful check. (See also Sec. 12 on the Quark Model.)

34. KINEMATICS

Revised May 1996.

Throughout this section units are used in which $\hbar=c=1$. The following conversions are useful: $\hbar c=197.3$ MeV fm, $(\hbar c)^2=0.3894$ (GeV)² mb.

34.1. Lorentz transformations

The energy E and 3-momentum p of a particle of mass m form a 4-vector p = (E, p) whose square $p^2 \equiv E^2 - |p|^2 = m^2$. The velocity of the particle is $\beta = p/E$. The energy and momentum (E^*, p^*) viewed from a frame moving with velocity β_f are given by

$$\begin{pmatrix} E^{*} \\ p_{\parallel}^{*} \end{pmatrix} = \begin{pmatrix} \gamma_{f} & -\gamma_{f}\beta_{f} \\ -\gamma_{f}\beta_{f} & \gamma_{f} \end{pmatrix} \begin{pmatrix} E \\ p_{\parallel} \end{pmatrix} \;, \quad p_{T}^{*} = p_{T} \;, \tag{34.1}$$

where $\gamma_f = (1-\beta_f^2)^{-1/2}$ and p_T (p_{\parallel}) are the components of p perpendicular (parallel) to β_f . Other 4-vectors, such as the spacetime coordinates of events, of course transform in the same way. The scalar product of two 4-momenta $p_1 \cdot p_2 = E_1 E_2 - p_1 \cdot p_2$ is invariant (frame independent).

34.2. Center-of-mass energy and momentum

In the collision of two particles of masses m_1 and m_2 the total center-of-mass energy can be expressed in the Lorentz-invariant form

$$E_{\rm cm} = \left[(E_1 + E_2)^2 - (p_1 + p_2)^2 \right]^{1/2} ,$$

= $\left[m_1^2 + m_2^2 + 2E_1E_2(1 - \beta_1\beta_2\cos\theta) \right]^{1/2} ,$ (34.2)

where θ is the angle between the particles. In the frame where one particle (of mass m_2) is at rest (lab frame),

$$E_{\rm cm} = (m_1^2 + m_2^2 + 2E_{1\,\rm lab}\,m_2)^{1/2} \ . \tag{34.3}$$

The velocity of the center-of-mass in the lab frame is

$$\boldsymbol{\beta}_{\rm cm} = \boldsymbol{p}_{\rm lab} / (E_{1\,\rm lab} + m_2) , \qquad (34.4)$$

where $p_{lab} \equiv p_{1 \, lab}$ and

$$\gamma_{\rm cm} = (E_{1\,\rm lab} + m_2)/E_{\rm cm} \ . \tag{34.5}$$

The c.m. momenta of particles 1 and 2 are of magnitude

$$p_{\rm cm} = p_{\rm lab} \frac{m_2}{E_{\rm cm}} \ . \tag{34.6}$$

For example, if a 0.80 ${\rm GeV}/c$ kaon beam is incident on a proton target, the center of mass energy is 1.699 ${\rm GeV}$ and the center of mass momentum of either particle is 0.442 ${\rm GeV}/c$. It is also useful to note that

$$E_{\rm cm} dE_{\rm cm} = m_2 dE_{1 \, \rm lab} = m_2 \, \beta_{1 \, \rm lab} \, dp_{\rm lab} \, .$$
 (34.7)

34.3. Lorentz-invariant amplitudes

The matrix elements for a scattering or decay process are written in terms of an invariant amplitude $-i\mathcal{M}$. As an example, the S-matrix for $2 \to 2$ scattering is related to \mathcal{M} by

$$\langle p'_1 p'_2 | S | p_1 p_2 \rangle = I - i(2\pi)^4 \, \delta^4(p_1 + p_2 - p'_1 - p'_2)$$

$$\times \frac{\mathscr{M}(p_1, p_2; p'_1, p'_2)}{(2E_1)^{1/2} \, (2E_2)^{1/2} \, (2E'_1)^{1/2} \, (2E'_2)^{1/2}} \,. \tag{34.8}$$

The state normalization is such that

$$\langle p'|p\rangle = (2\pi)^3 \delta^3(\boldsymbol{p} - \boldsymbol{p}') . \tag{34.9}$$

34.4. Particle decays

The partial decay rate of a particle of mass M into n bodies in its rest frame is given in terms of the Lorentz-invariant matrix element \mathcal{M} by

$$d\Gamma = \frac{(2\pi)^4}{2M} |\mathcal{M}|^2 d\Phi_n (P; p_1, \dots, p_n), \tag{34.10}$$

where $d\Phi_n$ is an element of n-body phase space given by

$$d\Phi_n(P; p_1, \dots, p_n) = \delta^4 \left(P - \sum_{i=1}^n p_i \right) \prod_{i=1}^n \frac{d^3 p_i}{(2\pi)^3 2E_i} . \tag{34.11}$$

This phase space can be generated recursively, viz.

$$d\Phi_n(P; p_1, \dots, p_n) = d\Phi_j(q; p_1, \dots, p_j)$$

$$\times d\Phi_{n-j+1}(P; q, p_{i+1}, \dots, p_n)(2\pi)^3 dq^2, \qquad (34.12)$$

where $q^2 = (\sum_{i=1}^j E_i)^2 - \left|\sum_{i=1}^j p_i\right|^2$. This form is particularly useful in the case where a particle decays into another particle that subsequently decays.

34.4.1. Survival probability: If a particle of mass M has mean proper lifetime τ (= $1/\Gamma$) and has momentum (E, p), then the probability that it lives for a time t_0 or greater before decaying is given by

$$P(t_0) = e^{-t_0 \Gamma/\gamma} = e^{-Mt_0 \Gamma/E} , \qquad (34.13)$$

and the probability that it travels a distance x_0 or greater is

$$P(x_0) = e^{-Mx_0 \Gamma/|\mathbf{p}|} . {(34.14)}$$

34.4.2. Two-body decays:

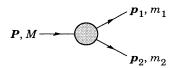

Figure 34.1: Definitions of variables for two-body decays.

In the rest frame of a particle of mass M, decaying into 2 particles labeled 1 and 2,

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M} \,, \tag{34.15}$$

 $|\boldsymbol{p}_1| = |\boldsymbol{p}_2|$

$$=\frac{\left[\left(M^2-(m_1+m_2)^2\right)\left(M^2-(m_1-m_2)^2\right)\right]^{1/2}}{2M},\quad (34.16)$$

and

$$d\Gamma = \frac{1}{32\pi^2} |\mathcal{M}|^2 \frac{|\mathbf{p}_1|}{M^2} d\Omega , \qquad (34.17)$$

where $d\Omega = d\phi_1 d(\cos \theta_1)$ is the solid angle of particle 1.

34.4.3. Three-body decays:

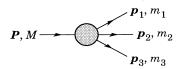

Figure 34.2: Definitions of variables for three-body decays.

Defining $p_{ij}=p_i+p_j$ and $m_{ij}^2=p_{ij}^2$, then $m_{12}^2+m_{23}^2+m_{13}^2=M^2+m_1^2+m_2^2+m_3^2$ and $m_{12}^2=(P-p_3)^2=M^2+m_3^2-2ME_3$, where E_3 is the energy of particle 3 in the rest frame of M. In that frame, the momenta of the three decay particles lie in a plane. The relative orientation of these three momenta is fixed if their energies are known. The momenta can therefore be specified in space by giving three Euler angles (α,β,γ) that specify the orientation of the final system relative to the initial particle. Then

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M} |\mathcal{M}|^2 dE_1 dE_2 d\alpha d(\cos\beta) d\gamma . \tag{34.18}$$

Alternatively

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M^2} |\mathcal{M}|^2 |\mathbf{p}_1^*| |\mathbf{p}_3| dm_{12} d\Omega_1^* d\Omega_3 , \qquad (34.19)$$

where $(|\boldsymbol{p}_1^*|, \Omega_1^*)$ is the momentum of particle 1 in the rest frame of 1 and 2, and Ω_3 is the angle of particle 3 in the rest frame of the decaying particle. $|\boldsymbol{p}_1^*|$ and $|\boldsymbol{p}_3|$ are given by

$$|\mathbf{p}_{1}^{*}| = \frac{\left[\left(m_{12}^{2} - (m_{1} + m_{2})^{2}\right)\left(m_{12}^{2} - (m_{1} - m_{2})^{2}\right)\right]^{1/2}}{2m_{12}},$$
(34.20a)

and

$$|\mathbf{p}_3| = \frac{\left[\left(M^2 - (m_{12} + m_3)^2\right)\left(M^2 - (m_{12} - m_3)^2\right)\right]^{1/2}}{2M}$$
 (34.20b)

[Compare with Eq. (34.16).]

If the decaying particle is a scalar or we average over its spin states, then integration over the angles in Eq. (34.18) gives

$$d\Gamma = \frac{1}{(2\pi)^3} \frac{1}{8M} |\mathcal{M}|^2 dE_1 dE_2$$

$$= \frac{1}{(2\pi)^3} \frac{1}{32M^3} |\mathcal{M}|^2 dm_{12}^2 dm_{23}^2.$$
(34.21)

This is the standard form for the Dalitz plot.

34.4.3.1. Dalitz plot: For a given value of m_{12}^2 , the range of m_{23}^2 is determined by its values when p_2 is parallel or antiparallel to p_3 :

$$(m_{23}^2)_{\text{max}} =$$

$$(E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} - \sqrt{E_3^{*2} - m_3^2}\right)^2$$
, (34.22a)

 $(m_{23}^2)_{\min} =$

$$(E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} + \sqrt{E_3^{*2} - m_3^2}\right)^2$$
 (34.22b)

Here $E_2^* = (m_{12}^2 - m_1^2 + m_2^2)/2m_{12}$ and $E_3^* = (M^2 - m_{12}^2 - m_3^2)/2m_{12}$ are the energies of particles 2 and 3 in the m_{12} rest frame. The scatter plot in m_{12}^2 and m_{23}^2 is called a Dalitz plot. If $|\mathcal{M}|^2$ is constant, the allowed region of the plot will be uniformly populated with events [see Eq. (34.21)]. A nonuniformity in the plot gives immediate information on $|\mathcal{M}|^2$. For example, in the case of $D \to K\pi\pi$, bands appear when $m_{(K\pi)} = m_{K^*(892)\pi}$, reflecting the appearance of the decay chain $D \to K^*(892)\pi \to K\pi\pi$.

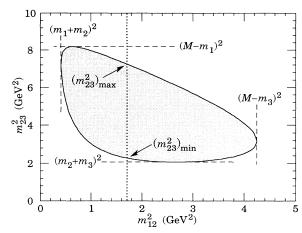

Figure 34.3: Dalitz plot for a three-body final state. In this example, the state is $\pi^+\overline{K}{}^0p$ at 3 GeV. Four-momentum conservation restricts events to the shaded region.

34.4.4. Kinematic limits: In a three-body decay the maximum of $|\mathbf{p}_3|$, [given by Eq. (34.20)], is achieved when $m_{12}=m_1+m_2$, i.e., particles 1 and 2 have the same vector velocity in the rest frame of the decaying particle. If, in addition, $m_3>m_1,m_2$, then $|\mathbf{p}_3|_{\max}>|\mathbf{p}_1|_{\max}$, $|\mathbf{p}_2|_{\max}$.

34.4.5. *Multibody decays*: The above results may be generalized to final states containing any number of particles by combining some of the particles into "effective particles" and treating the final states as 2 or 3 "effective particle" states. Thus, if $p_{ijk...} = p_i + p_j + p_k + \ldots$, then

$$m_{ijk...} = \sqrt{p^2_{ijk...}} , \qquad (34.23)$$

and $m_{ijk...}$ may be used in place of $e.g.,\ m_{12}$ in the relations in Sec. 34.4.3 or 34.4.3.1 above.

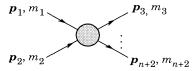

Figure 34.4: Definitions of variables for production of an n-body final state.

34.5. Cross sections

The differential cross section is given by

$$d\sigma = \frac{(2\pi)^4 |\mathcal{M}|^2}{4\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2}} \times d\Phi_n(p_1 + p_2; p_3, \dots, p_{n+2}).$$
(34.24)

[See Eq. (34.11).] In the rest frame of $m_2(lab)$,

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = m_2 p_{1 \, \text{lab}} ; \qquad (34.25a)$$

while in the center-of-mass frame

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = p_{1\text{cm}} \sqrt{s} . \tag{34.25b}$$

34.5.1. Two-body reactions:

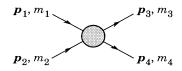

Figure 34.5: Definitions of variables for a two-body final state.

Two particles of momenta p_1 and p_2 and masses m_1 and m_2 scatter to particles of momenta p_3 and p_4 and masses m_3 and m_4 ; the Lorentz-invariant Mandelstam variables are defined by

$$s = (p_1 + p_2)^2 = (p_3 + p_4)^2$$

$$= m_1^2 + 2E_1E_2 - 2\mathbf{p}_1 \cdot \mathbf{p}_2 + m_2^2 , \qquad (34.26)$$

$$t = (p_1 - p_3)^2 = (p_2 - p_4)^2$$

$$= m_1^2 - 2E_1E_3 + 2\mathbf{p}_1 \cdot \mathbf{p}_3 + m_3^2 , \qquad (34.27)$$

$$u = (p_1 - p_4)^2 = (p_2 - p_3)^2$$

$$= m_1^2 - 2E_1E_4 + 2\mathbf{p}_1 \cdot \mathbf{p}_4 + m_4^2 , \qquad (34.28)$$

and they satisfy

$$s + t + u = m_1^2 + m_2^2 + m_3^2 + m_4^2 . (34.29)$$

The two-body cross section may be written as

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s} \frac{1}{|\mathbf{p}_{1cm}|^2} |\mathcal{M}|^2.$$
 (34.30)

In the center-of-mass frame

$$t = (E_{1\text{cm}} - E_{3\text{cm}})^2 - (p_{1\text{cm}} - p_{3\text{cm}})^2$$
$$-4p_{1\text{cm}} p_{3\text{cm}} \sin^2(\theta_{\text{cm}}/2)$$
$$= t_0 - 4p_{1\text{cm}} p_{3\text{cm}} \sin^2(\theta_{\text{cm}}/2) , \qquad (34.31)$$

where $\theta_{\rm cm}$ is the angle between particle 1 and 3. The limiting values t_0 ($\theta_{\rm cm}=0$) and t_1 ($\theta_{\rm cm}=\pi$) for $2\to 2$ scattering are

$$t_0(t_1) = \left[\frac{m_1^2 - m_3^2 - m_2^2 + m_4^2}{2\sqrt{s}} \right]^2 - (p_{1\,\text{cm}} \mp p_{3\,\text{cm}})^2 . \tag{34.32}$$

In the literature the notation t_{\min} (t_{\max}) for t_0 (t_1) is sometimes used, which should be discouraged since $t_0 > t_1$. The center-of-mass energies and momenta of the incoming particles are

$$E_{1\text{cm}} = \frac{s + m_1^2 - m_2^2}{2\sqrt{s}} , \qquad E_{2\text{cm}} = \frac{s + m_2^2 - m_1^2}{2\sqrt{s}} ,$$
 (34.33)

For $E_{3\rm cm}$ and $E_{4\rm cm}$, change m_1 to m_3 and m_2 to m_4 . Then

$$p_{i\,{\rm cm}} = \sqrt{E_{i\,{\rm cm}}^2 - m_i^2}$$
 and $p_{1{\rm cm}} = \frac{p_{1\,{\rm lab}} \, m_2}{\sqrt{s}}$. (34.34)

Here the subscript lab refers to the frame where particle 2 is at rest. [For other relations see Eqs. (34.2)–(34.4).]

34.5.2. *Inclusive reactions*: Choose some direction (usually the beam direction) for the z-axis; then the energy and momentum of a particle can be written as

$$E = m_T \cosh y \; , \; p_x \; , \; p_y \; , \; p_z = m_T \sinh y \; , \qquad (34.35)$$

where m_T is the transverse mass

$$m_T^2 = m^2 + p_x^2 + p_y^2 \; , \tag{34.36} \label{eq:34.36}$$

and the rapidity y is defined by

$$\begin{split} y &= \frac{1}{2} \ln \left(\frac{E + p_z}{E - p_z} \right) \\ &= \ln \left(\frac{E + p_z}{m_T} \right) = \tanh^{-1} \left(\frac{p_z}{E} \right) \;. \end{split} \tag{34.37}$$

Under a boost in the z-direction to a frame with velocity β , $y \to y - \tanh^{-1} \beta$. Hence the shape of the rapidity distribution dN/dy is invariant. The invariant cross section may also be rewritten

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi\,dy\,p_Tdp_T} \Longrightarrow \frac{d^2\sigma}{\pi\,dy\,d(p_T^2)}\;. \tag{34.38}$$

The second form is obtained using the identity $dy/dp_z = 1/E$, and the third form represents the average over ϕ .

Feynman's x variable is given by

$$x = \frac{p_z}{p_{z\,\mathrm{max}}} \approx \frac{E + p_z}{(E + p_z)_{\mathrm{max}}} \quad (p_T \ll |p_z|) \ . \tag{34.39} \label{eq:34.39}$$

In the c.m. frame

$$x \approx \frac{2p_{z\,\text{cm}}}{\sqrt{s}} = \frac{2m_T \sinh y_{\text{cm}}}{\sqrt{s}} \tag{34.40}$$

and

$$= (y_{\rm cm})_{\rm max} = \ln(\sqrt{s}/m)$$
 (34.41)

For $p \gg m$, the rapidity [Eq. (34.37)] may be expanded to obtain

$$y = \frac{1}{2} \ln \frac{\cos^2(\theta/2) + m^2/4p^2 + \dots}{\sin^2(\theta/2) + m^2/4p^2 + \dots}$$

$$\approx -\ln \tan(\theta/2) \equiv \eta$$
 (34.42)

where $\cos\theta = p_z/p$. The pseudorapidity η defined by the second line is approximately equal to the rapidity y for $p\gg m$ and $\theta\gg 1/\gamma$, and in any case can be measured when the mass and momentum of the particle is unknown. From the definition one can obtain the identities

$$\sinh \eta = \cot \theta$$
, $\cosh \eta = 1/\sin \theta$, $\tanh \eta = \cos \theta$. (34.43)

34.5.3. *Partial waves*: The amplitude in the center of mass for elastic scattering of spinless particles may be expanded in Legendre polynomials

$$f(k,\theta) = \frac{1}{k} \sum_{\ell} (2\ell + 1) a_{\ell} P_{\ell}(\cos \theta) ,$$
 (34.44)

where k is the c.m. momentum, θ is the c.m. scattering angle, $a_{\ell} = (\eta_{\ell}e^{2i\delta_{\ell}} - 1)/2i$, $0 \le \eta_{\ell} \le 1$, and δ_{ℓ} is the phase shift of the ℓ^{th} partial wave. For purely elastic scattering, $\eta_{\ell} = 1$. The differential cross section is

$$\frac{d\sigma}{d\Omega} = |f(k,\theta)|^2 \ . \tag{34.45}$$

The optical theorem states that

$$\sigma_{\text{tot}} = \frac{4\pi}{k} \text{Im} f(k,0) , \qquad (34.46)$$

and the cross section in the ℓ^{th} partial wave is therefore bounded:

$$\sigma_{\ell} = \frac{4\pi}{k^2} (2\ell + 1)|a_{\ell}|^2 \le \frac{4\pi (2\ell + 1)}{k^2} \ . \tag{34.47}$$

The evolution with energy of a partial-wave amplitude a_{ℓ} can be displayed as a trajectory in an Argand plot, as shown in Fig. 34.6.

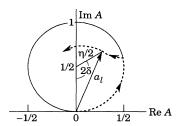

Figure 34.6: Argand plot showing a partial-wave amplitude a_{ℓ} as a function of energy. The amplitude leaves the unitary circle where inelasticity sets in $(\eta_{\ell} < 1)$.

The usual Lorentz-invariant matrix element \mathcal{M} (see Sec. 34.3 above) for the elastic process is related to $f(k,\theta)$ by

$$\mathcal{M} = -8\pi\sqrt{s} \ f(k,\theta) \ , \tag{34.48}$$

so

$$\sigma_{\text{tot}} = -\frac{1}{2p_{\text{lab}} m_2} \text{Im} \mathcal{M}(t=0) ,$$
 (34.49)

where s and t are the center-of-mass energy squared and momentum transfer squared, respectively (see Sec. 34.4.1).

34.5.3.1. Resonances: The Breit-Wigner (nonrelativistic) form for an elastic amplitude a_ℓ with a resonance at c.m. energy E_R , elastic width $\Gamma_{\rm el}$, and total width $\Gamma_{\rm tot}$ is

$$a_{\ell} = \frac{\Gamma_{\rm cl}/2}{E_R - E - i\Gamma_{\rm tot}/2} , \qquad (34.50)$$

where E is the c.m. energy. As shown in Fig. 34.7, in the absence of background the elastic amplitude traces a counterclockwise circle with center $ix_{\rm cl}/2$ and radius $x_{\rm cl}/2$, where the elasticity $x_{\rm cl}=\Gamma_{\rm cl}/\Gamma_{\rm tot}$. The amplitude has a pole at $E=E_R-i\Gamma_{\rm tot}/2$.

The spin-averaged Breit-Wigner cross section for a spin-J resonance produced in the collision of particles of spin S_1 and S_2 is

$$\sigma_{BW}(E) = \frac{(2J+1)}{(2S_1+1)(2S_2+1)} \frac{\pi}{k^2} \frac{B_{\rm in} B_{\rm out} \Gamma_{\rm tot}^2}{(E-E_R)^2 + \Gamma_{\rm tot}^2/4} \ , \ (34.51)$$

where k is the c.m. momentum, E is the c.m. energy, and $B_{\rm in}$ and $B_{\rm out}$ are the branching fractions of the resonance into the entrance and exit channels. The 2S+1 factors are the multiplicities of the incident spin states, and are replaced by 2 for photons. This expression is valid only for an isolated state. If the width is not small, $\Gamma_{\rm tot}$ cannot be treated as a constant independent of E. There are many other forms for σ_{BW} , all of which are equivalent to the one given here in the narrow-width case. Some of these forms may be more appropriate if the resonance is broad.

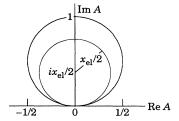

Figure 34.7: Argand plot for a resonance. The relativistic Breit-Wigner form corresponding to Eq. (34.50) is:

$$a_{\ell} = \frac{-m\Gamma_{\rm cl}}{s - m^2 + im\Gamma_{\rm tot}} \ . \tag{34.52} \label{eq:alpha}$$

A better form incorporates the known kinematic dependences, replacing $m\Gamma_{\rm tot}$ by $\sqrt{s}\,\Gamma_{\rm tot}(s)$, where $\Gamma_{\rm tot}(s)$ is the width the resonance particle would have if its mass were \sqrt{s} , and correspondingly $m\Gamma_{\rm cl}$ by $\sqrt{s}\,\Gamma_{\rm cl}(s)$ where $\Gamma_{\rm cl}(s)$ is the partial width in the incident channel for a mass \sqrt{s} :

$$a_{\ell} = \frac{-\sqrt{s} \Gamma_{\rm cl}(s)}{s - m^2 + i\sqrt{s} \Gamma_{\rm tot}(s)} \,. \tag{34.53}$$

For the Z boson, all the decays are to particles whose masses are small enough to be ignored, so on dimensional grounds $\Gamma_{\rm tot}(s) = \sqrt{s}\,\Gamma_0/m_Z$, where Γ_0 defines the width of the Z, and $\Gamma_{\rm cl}(s)/\Gamma_{\rm tot}(s)$ is constant. A full treatment of the line shape requires consideration of dynamics, not just kinematics. For the Z this is done by calculating the radiative corrections in the Standard Model.

35. CROSS-SECTION FORMULAE FOR SPECIFIC PROCESSES

35.1. Leptoproduction

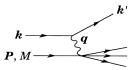

Figure 35.1: Kinematic quantities for description of lepton-nucleon scattering. k and k' are the four-momenta of incoming and outgoing leptons, P is the four-momentum of a nucleon with mass M. The exchanged particle is a γ , W^{\pm} , or Z^0 ; it transfers four-momentum q=k-k' to the target.

Invariant quantities:

 $\nu = \frac{q \cdot P}{M} = E - E' \text{is the lepton's energy loss in the lab (in earlier literature sometimes } \nu = q \cdot P). \text{ Here, } E \text{ and } E' \text{ are the initial and final lepton energies in the lab.}$

$$\begin{split} Q^2 = -q^2 = 2(EE' - \overrightarrow{k} \cdot \overrightarrow{k}') - m_\ell^2 - m_{\ell'}^2 \text{ where } m_\ell(m_{\ell'}) \text{ is the initial} \\ \text{(final) lepton mass. If } EE' \sin^2(\theta/2) \gg m_\ell^2, \, m_{\ell'}^2, \text{ then} \end{split}$$

 $\approx 4EE'\sin^2(\theta/2)$, where θ is the lepton's scattering angle in the lab.

 $x=rac{Q^2}{2M
u}$ In the parton model, x is the fraction of the target nucleon's momentum carried by the struck quark. [See section on Quantum Chromodynamics (Sec. 9 of this Review.]

 $y = \frac{q \cdot P}{k \cdot P} = \frac{\nu}{E}$ is the fraction of the lepton's energy lost in the lab.

 $W^2 = (P+q)^2 = M^2 + 2M\nu - Q^2$ is the mass squared of the system recoiling against the lepton.

$$s = (k+P)^2 = \frac{Q^2}{xy} + M^2$$

35.1.1. Leptoproduction cross sections:

$$\frac{d^2\sigma}{dx\,dy} = \nu \left(s - M^2\right) \frac{d^2\sigma}{d\nu\,dQ^2} = \frac{2\pi\,M\nu}{E'} \frac{d^2\sigma}{d\Omega_{\rm lab}\,dE'}$$
$$= x(s - M^2) \frac{d^2\sigma}{dx\,dQ^2} \,. \tag{35.1}$$

35.1.2. Electroproduction structure functions: The neutral-current process, $eN \to eX$, is parity conserving at low Q^2 and can be written in terms of two structure functions $F_1^{\rm NC}(x,Q^2)$ and $F_2^{\rm NC}(x,Q^2)$:

$$\frac{d^2\sigma}{dx\,dy} = \frac{4\pi\,\alpha^2(s-M^2)}{Q^4} \times \left[(1-y)\,F_2^{\rm NC} + \,y^2\,xF_1^{\rm NC} - \frac{M^2}{(s-M^2)}\,xy\,F_2^{\rm NC} \right] \,. \quad (35.2)$$

The charged-current processes, $e^-N \to \nu X$, $\nu N \to e^-X$, and $\overline{\nu}N \to e^+X$, are parity violating and can be written in terms of three structure functions $F_1^{\text{CC}}(x,Q^2)$, $F_2^{\text{CC}}(x,Q^2)$, and $F_3^{\text{CC}}(x,Q^2)$:

$$\frac{d^2\sigma}{dx\,dy} = \frac{G_F^2\,(s-M^2)}{2\pi} \frac{M_W^4}{(Q^2 + M_W^2)^2} \tag{35.3}$$

$$\times \ \left\{ \left[1 - y - \frac{M^2 x y}{(s - M^2)} \right] F_2^{\rm CC} + \frac{y^2}{2} \ 2x \, F_1^{\rm CC} \pm (y - \frac{y^2}{2}) \ x \, F_3^{\rm CC} \right\} \, ,$$

where the last term is positive for the e^- and ν reactions and negative for $\overline{\nu}N \to e^+ X$.

35.1.3. The QCD parton model: In the QCD parton model, the structure functions defined above can be expressed in terms of parton distribution functions. The quantity $f_i(x,Q^2)dx$ is the probability that a parton of type i (quark, antiquark, or gluon), carries a momentum fraction between x and x+dx of the nucleon's momentum in a frame where the nucleon's momentum is large. For the cross section corresponding to the neutral-current process $ep \to eX$, we have for $s \gg M^2$ (in the case where the incoming electron is either left- (L) or right- (R) handed):

$$\frac{d^2\sigma}{dx\,dy} = \frac{\pi\alpha^2}{sx^2\,y^2} \left[\sum_q (x\,f_q\,(x,\,Q^2) + x\,f_{\overline{q}}\,(x,\,Q^2)) \right]
\times \left[A_q + (1-y)^2\,B_q \right] .$$
(35.4)

Here the index q refers to a quark flavor (i.e., u, d, s, c, b, or t), and

$$A_q = \left(-q_q + g_{Lq} g_{Le} \frac{Q^2}{Q^2 + M_Z^2}\right)^2 + \left(-q_q + g_{Rq} g_{Re} \frac{Q^2}{Q^2 + M_Z^2}\right)^2,$$
(35.3)

$$B_q = \left(-q_q + g_{Rq} g_{Le} \frac{Q^2}{Q^2 + M_Z^2}\right)^2 + \left(-q_q + g_{Lq} g_{Re} \frac{Q^2}{Q^2 + M_Z^2}\right)^2.$$
(35.6)

Here q_q is the charge of flavor q. For a left-handed electron, $g_{Re}=0$ and $g_{Le}=(-1/2+\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$, while for a right-handed one, $g_{Le}=0$ and $g_{Re}=(\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$. For the quarks, $g_{Lq}=(T_3-q_q\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$, and $g_{Rq}=(-q_q\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$.

For neutral-current neutrino (antineutrino) scattering, the same formula applies with g_{Le} replaced by $g_{L\nu}=1/(2\sin\theta_W\cos\theta_W)$ ($g_{L\overline{\nu}}=0$) and g_{Re} replaced by $g_{R\nu}=0$ [$g_{R\overline{\nu}}=-1/(2\sin\theta_W\cos\theta_W)$].

In the case of the charged-current processes $e_L^- p \to \nu X$ and $\bar{\nu}p \to e^+ X$, Eq. (35.3) applies with

$$F_{2} = 2xF_{1} = 2x \left[f_{u}(x, Q^{2}) + f_{c}(x, Q^{2}) + f_{t}(x, Q^{2}) + f_{\overline{d}}(x, Q^{2}) + f_{\overline{b}}(x, Q^{2}) + f_{\overline{b}}(x, Q^{2}) \right], \quad (35.7)$$

$$F_{3} = 2 \left[f_{u}(x, Q^{2}) + f_{c}(x, Q^{2}) + f_{\overline{b}}(x, Q^{2}) - f_{\overline{b}}(x, Q^{2}) - f_{\overline{b}}(x, Q^{2}) \right]. \quad (35.8)$$

For the process $\nu p \to e^- X$:

$$\begin{split} F_2 &= 2x F_1 = 2x \Big[f_d(x,Q^2) + f_s(x,Q^2) \\ &+ f_b(x,Q^2) + f_{\overline{u}}\left(x,Q^2\right) + f_{\overline{c}}\left(x,Q^2\right) + f_{\overline{t}}\left(x,Q^2\right) \Big] \;, \; (35.9) \\ F_3 &= 2 \Big[f_d(x,Q^2) + f_s(x,Q^2) \\ &+ f_b(x,Q^2) - f_{\overline{u}}\left(x,Q^2\right) - f_{\overline{c}}\left(x,Q^2\right) - f_{\overline{t}}\left(x,Q^2\right) \Big] \;. (35.10) \end{split}$$

35.2. e^+e^- annihilation

For pointlike spin-1/2 fermions in the c.m., the differential cross section for $e^+e^-\to f\bar f$ via single photon annihilation is

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4s} \beta \left[1 + \cos^2 \theta + (1 - \beta^2) \sin^2 \theta \right] Q_f^2 , \qquad (35.11)$$

where β is the velocity of the final state fermion in the center of mass and Q_f is the charge of the fermion in units of the proton charge. For $\beta \to 1$,

$$\sigma = \frac{4\pi\alpha^2}{3s} Q_f^2 = \frac{86.8 Q_f^2 nb}{s(\text{GeV}^2)} . \tag{35.12}$$

At higher energies the Z^0 (mass M_Z and width Γ_Z) must be included, and the differential cross section for $e^+e^-\to f\bar f$ becomes

$$\begin{split} \frac{d\sigma}{d\Omega} &= \frac{\alpha^2}{4s} \,\beta \, \left[Q_f^2 [1 + \cos^2 \theta + (1 - \beta^2) \, \sin^2 \theta \,] \right. \\ &- 2Q_f \,\chi_1 \bigg\{ VV_f \, [1 + \cos^2 \theta + (1 - \beta^2) \, \sin^2 \theta \,] - 2a_f \,\beta \cos \theta \bigg\} \\ &+ \chi_2 \bigg\{ V_f^2 \, (1 + V^2) \, [1 + \cos^2 \theta + (1 - \beta^2) \, \sin^2 \theta \,] \\ &+ \beta^2 \, a_f^2 (1 + V^2) \, [1 + \cos^2 \theta \,] - 8\beta \, VV_f \, a_f \cos \theta \bigg\} \bigg] \,\,, \end{split}$$
 (35.13)

$$\chi_1 = \frac{1}{16\sin^2\theta_W \cos^2\theta_W} \frac{s(s - M_Z^2)}{(s - M_Z^2)^2 + \Gamma_Z^2 M_Z^2},$$
 (35.14)

$$\chi_2 = \frac{1}{256 \sin^4 \theta_W \cos^4 \theta_W} \frac{s^2}{(s - M_Z^2)^2 + \Gamma_Z^2 M_Z^2} , \qquad (35.15)$$

$$V = -1 + 4\sin^2\theta_W , (35.16)$$

$$a_f = 2T_{3f} ag{5.17}$$

where the subscript f refers to the particular fermion and

$$T_3 = +1/2$$
 for ν_e , ν_μ , ν_τ , u , c , t , (35.19a)

$$T_3 = -1/2$$
 for $e^-, \mu^-, \tau^-, d, s, b.$ (35.19b)

35.3. Two-photon process at e^+e^- colliders

When an e^+ and an e^- collide with energies E_1 and E_2 , they emit dn_1 and dn_2 virtual photons with energies ω_1 and ω_2 and 4-momenta q_1 and q_2 . In the equivalent photon approximation, the cross section for $e^+e^- \to e^+e^-X$ is related to the cross section for $\gamma\gamma \to X$ by (Ref. 1)

$$d\sigma_{e^+e^-\to e^+e^-Y}(s) = dn_1 dn_2 d\sigma_{\gamma\gamma\to X}(W^2)$$
(35.20)

where $s = 4E_1E_2$, $W^2 = 4\omega_1\omega_2$ and

$$dn_i = \frac{\alpha}{\pi} \left[1 - \frac{\omega_i}{E_i} + \frac{\omega_i^2}{2E_i^2} - \frac{m_e^2 \omega_i^2}{(-q_i^2)E_i^2} \right] \frac{d\omega_i}{\omega_i} \frac{d(-q_i^2)}{(-q_i^2)} . \tag{35.21}$$

After integration (including that over q_i^2 in the region $m_e^2 \omega_i^2 / E_i(E_i - \omega_i) \le -q_i^2 \le (-q^2)_{\rm max}$), the cross section is

$$\begin{split} \sigma_{e^+e^-\to e^+e^-X}\left(s\right) = & \frac{\alpha^2}{\pi^2} \int_{z_{th}}^1 \frac{dz}{z} \left[f(z) \left(\ln \frac{(-q^2)_{\text{max}}}{m_e^2 z} - 1 \right)^2 \right. \\ & \left. - \frac{1}{3} \left(\ln \frac{1}{z} \right)^3 \right] \sigma_{\gamma\gamma\to X}\left(zs\right) \,; \end{split}$$

$$f(z) = \left(1 + \frac{1}{2}z\right)^2 \ln\frac{1}{z} - \frac{1}{2}(1 - z)(3 + z) ;$$

$$z = \frac{W^2}{s} . \tag{35.22}$$

The quantity $(-q^2)_{\max}$ depends on properties of the produced system X, in particular, $(-q^2)_{\max} \sim m_{\rho}^2$ for hadron production (X = h) and $(-q^2)_{\max} \sim W^2$ for lepton pair production $(X = \ell^+\ell^-, \ell^-, \ell^-, \ell^-)$.

For production of a resonance of mass m_R and spin $J \neq 1$

$$\begin{split} &\sigma_{e^+e^-\to e^+e^-R}\left(s\right) = (2J+1)\frac{8\alpha^2\Gamma_{R\to\gamma\gamma}}{m_R^3} \\ &\times \left[f(m_R^2/s) \left(\ln\frac{sm_V^2}{m_e^2m_R^2} - 1\right)^2 - \frac{1}{3} \left(\ln\frac{s}{m_P^2}\right)^3\right] \end{split} \tag{35.23}$$

where m_V is the mass that enters into the form factor of the $\gamma\gamma \to R$ transition: $m_V \sim m_\rho$ for $R=\pi^0,\,\rho^0,\,\omega,\,\phi,\,\ldots,\,m_V \sim m_R$ for $R=c\overline{c}$ or $b\overline{b}$ resonances.

35.4. Inclusive hadronic reactions

One-particle inclusive cross sections $Ed^3\sigma/d^3p$ for the production of a particle of momentum p are conveniently expressed in terms of rapidity (see above) and the momentum p_T transverse to the beam direction (defined in the center-of-mass frame)

$$E \frac{d^3 \sigma}{d^3 p} = \frac{d^3 \sigma}{d \phi \; dy \; p_T dp_T} \; . \tag{35.24}$$

In the case of processes where p_T is large or the mass of the produced particle is large (here large means greater than 10 GeV), the parton model can be used to calculate the rate. Symbolically

$$\sigma_{\text{hadronic}} = \sum_{ij} \int f_i(x_1, Q^2) f_j(x_2, Q^2) dx_1 dx_2 \, \hat{\sigma}_{\text{partonic}} ,$$
 (35.25)

where $f_i(x, Q^2)$ is the parton distribution introduced above and Q is a typical momentum transfer in the partonic process and $\widehat{\sigma}$ is the partonic cross section. Two examples will help to clarify. The production of a W^+ in pp reactions at rapidity y in the center-of-mass frame is given by

$$\begin{split} \frac{d\sigma}{dy} &= \frac{G_F \, \pi \sqrt{2}}{3} \\ &\times \tau \bigg[\cos^2 \theta_c \bigg(u(x_1 \, , \, M_W^2) \, \overline{d} \, (x_2, M_W^2) \\ &\quad + \, u(x_2 \, , \, M_W^2) \, \overline{d} \, (x_1, M_W^2) \bigg) \\ &\quad + \, \sin^2 \theta_c \bigg(u(x_1 \, , \, M_W^2) \, \overline{s} \, (x_2 \, , \, M_W^2) \\ &\quad + \, s(x_2, M_W^2) \, \overline{u} \, (x_1, M_W^2) \bigg) \bigg] \, , \end{split}$$
 (35.26)

where $x_1 = \sqrt{\tau} e^y$, $x_2 = \sqrt{\tau} e^{-y}$, and $\tau = M_W^2/s$. Similarly the production of a jet in pp (or $p\bar{p}$) collisions is given by

$$\frac{d^{3}\sigma}{d^{2}p_{T} dy} = \sum_{ij} \int f_{i}(x_{1}, p_{T}^{2}) f_{j}(x_{2}, p_{T}^{2})
\times \left[\widehat{s} \frac{d\widehat{\sigma}}{d\widehat{t}} \right]_{ij} dx_{1} dx_{2} \delta(\widehat{s} + \widehat{t} + \widehat{u}),$$
(35.27)

where the summation is over quarks, gluons, and antiquarks. Here

$$s = (p_1 + p_2)^2 (35.28)$$

$$t = (p_1 - p_{\text{jet}})^2 \,, \tag{35.29}$$

$$u = (p_2 - p_{\text{jet}})^2$$
, (35.30)

 p_1 and p_2 are the momenta of the incoming p and p (or \overline{p}) and \widehat{s} , \widehat{t} , and \widehat{u} are s, t, and u with $p_1 \to x_1 p_1$ and $p_2 \to x_2 p_2$. The partonic cross section $\widehat{s}[(d\widehat{\sigma})/(d\widehat{t})]$ can be found in Ref. 2. Example: for the process $gg \to q\overline{q}$,

$$\widehat{s} \, \frac{d\sigma}{dt} = 3\alpha_s^2 \, \frac{(\widehat{t}^{\,2} + \widehat{u}^2)}{8\widehat{s}} \, \left[\frac{4}{9\,\widehat{t}\,\widehat{u}} - \frac{1}{\widehat{s}^{\,2}} \right] \, . \tag{35.31}$$

The prediction of Eq. (35.27) is compared to data from the UA1 and UA2 collaborations in Fig. 36.7 in the Plots of Cross Sections and Related Quantities section of this *Review*.

35.5. One-particle inclusive distributions

In order to describe one-particle inclusive production in e^+e^- annihilation or deep inelastic scattering, it is convenient to introduce a fragmentation function $D_i^h\left(z,Q^2\right)$ where $D_i^h\left(z,Q^2\right)$ is the number of hadrons of type h and momentum between zp and (z+dz)p produced in the fragmentation of a parton of type i. The Q^2 evolution is predicted by QCD and is similar to that of the parton distribution functions [see section on Quantum Chromodynamics (Sec. 9 of this Review)]. The $D_i^h(z,Q^2)$ are normalized so that

$$\sum_{h} \int z D_i^h (z, Q^2) dz = 1 . {(35.32)}$$

If the contributions of the Z boson and three-jet events are neglected, the cross section for producing a hadron h in e^+e^- annihilation is given by

$$\frac{1}{\sigma_{\rm had}} \frac{d\sigma}{dz} = \frac{\sum_{i} e_{i}^{2} D_{i}^{h} (z, Q^{2})}{\sum_{i} e_{i}^{2}} , \qquad (35.33)$$

where e_i is the charge of quark-type i, $\sigma_{\rm had}$ is the total hadronic cross section, and the momentum of the hadron is $zE_{\rm cm}/2$.

In the case of deep inelastic muon scattering, the cross section for producing a hadron of energy E_h is given by

$$\frac{1}{\sigma_{\rm tot}} \, \frac{d\sigma}{dz} = \frac{\sum_i e_i^2 \, q_i(x,Q^2) \, D_i^h(z,Q^2)}{\sum_i e_i^2 \, q_i(x,Q^2)} \, , \tag{35.34} \label{eq:sigma}$$

where $E_h=\nu z$. (For the kinematics of deep inelastic scattering, see Sec. 34.4.2 of the Kinematics section of this *Review*.) The fragmentation functions for light and heavy quarks have a different z dependence; the former peak near z=0. They are illustrated in Fig. 36.13 in the section on Plots of Cross Sections and Related Quantities (Sec. 36 of this *Review*).

36. PLOTS OF CROSS SECTIONS AND RELATED QUANTITIES

NOTE: THE FIGURES IN THIS SECTION ARE INTENDED TO SHOW THE REPRESENTATIVE DATA. THEY ARE NOT MEANT TO BE COMPLETE COMPILATIONS OF ALL THE WORLD'S RELIABLE DATA.

Structure Functions

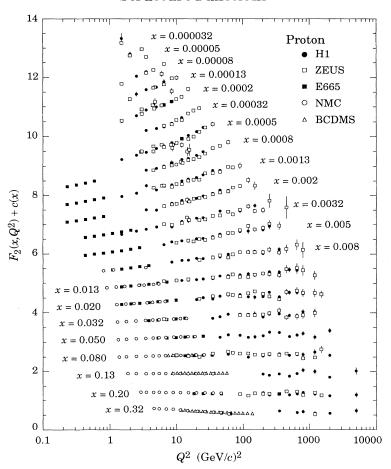

Figure 36.1: The proton structure function F_2^p measured in electromagnetic scattering of electrons (H1, ZEUS) and muons (BCDMS, E665, NMC), in the kinematic domain of the HERA data. Only statistical errors are shown. The data are plotted as a function of Q^2 in bins of fixed x. The H1 binning in x was chosen for this plot; the ZEUS, BCDMS, E665, and NMC data are rebinned to the x values of the H1 data using a phenomenological parametrization. For the purpose of plotting, a constant $c(x) = 0.6(i_x - 0.4)$ is added to F_2^p , where i_x is the number of the x bin ranging from $i_x = 1$ (x = 0.32) to $i_x = 21$ (x = 0.000032). References: H1—S. Aid et al., DESY 96-039 (1996), subm. to Nucl. Phys. B; ZEUS—M. Derrick et al., Z. Phys. C69, 607 (1996) and DESY 96-076 (1996), subm. to Z. Phys. C; BCDMS—A.C. Benvenuti et al., Phys. Lett. B223, 485 (1989); E665—M.R. Adams et al., FNAL-PUB-95/396-E, subm. to Phys. Rev. D; NMC—M. Arneodo et al., Phys. Lett. B364, 107 (1995). (Courtesy of R. Voss, 1996.)

Structure Functions

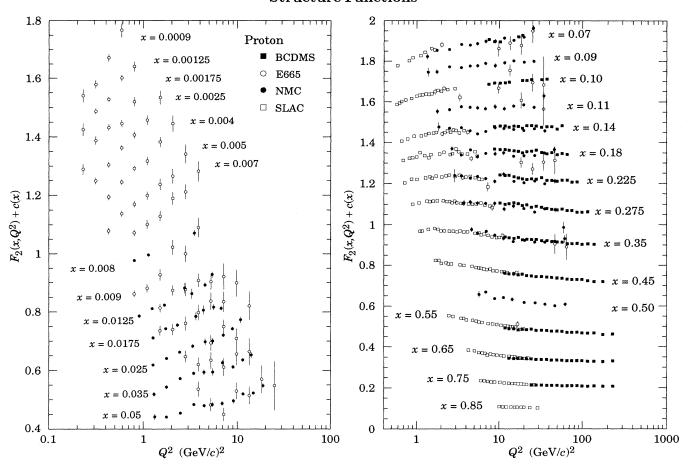

Figure 36.2: The proton structure function F_2^p measured in electromagnetic scattering of electrons (SLAC) and muons (BCDMS, E665, NMC), shown as a function of Q^2 for bins of fixed x. Only statistical errors are shown. For the purpose of plotting, a constant $c(x) = 0.1i_x$ is added to F_2^p where i_x is the number of the x bin, ranging from 1 (x = 0.05) to 14 (x = 0.0009) on the left-hand figure, and from 1 (x = 0.85) to 15 (x = 0.007) on the right-hand figure. For HERA data in the kinematic range of this figure, see Fig. 36.1. References: BCDMS—A.C. Benvenuti et al., Phys. Lett. B223, 485 (1989); E665—M.R. Adams et al., FNAL-PUB-95/396-E, subm. to Phys. Rev. D; NMC—M. Arneodo et al.Phys. Lett. B364, 107 (1995); SLAC—L.W. Whitlow et al., Phys. Lett. B282, 475 (1992). (Courtesy of R. Voss, 1996.)

Structure Functions

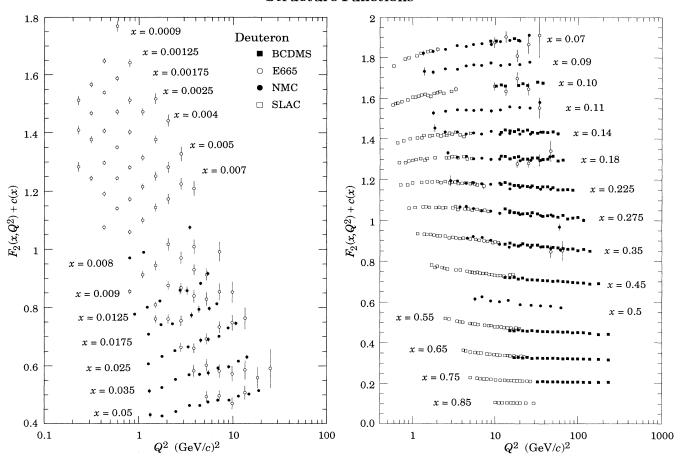

Figure 36.3: As Fig. 36.2, for the deuteron structure function F_2^d . References: BCDMS—A.C. Benvenuti *et al.*, Phys. Lett. B237, 592 (1990); E665, NMC, SLAC—same references as Fig. 36.2. (Courtesy of R. Voss, 1996.)

Structure Functions

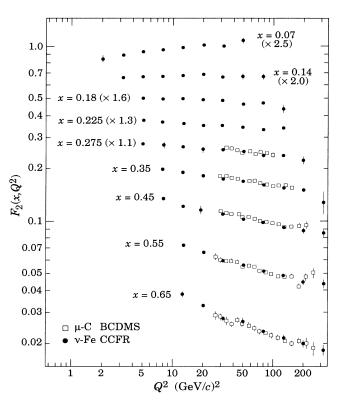

Figure 36.4: The nucleon structure function F_2 measured in deep inelastic scattering of muons on carbon (BCDMS) and neutrinos on iron (CCFR). The data are shown versus Q^2 , for bins of fixed x, and have been scaled by the factors shown in parentheses. References: BCDMS—A.C. Benvenuti *et al.*, Phys. Lett. B195, 91 (1987); CCFR—S.R. Mishra *et al.*, NEVIS-1465 (1992). (Courtesy of R. Voss, 1996.)

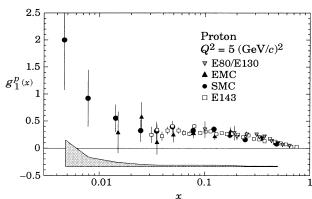

Figure 36.5: The spin-dependent structure function $g_1(x)$ of the proton measured in deep inelastic scattering of polarised electrons (E80, E130, E143) and muons (EMC, SMC), shown at $Q^2 = 5$ GeV². Only statistical

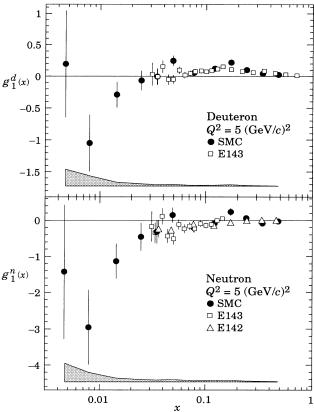

Figure 36.6: The spin-dependent structure function $g_1(x)$ of the deuteron and the neutron measured in deep inelastic scattering of polarised electrons (E142, E143) and muons (SMC), shown at $Q^2 = 5$ GeV². The SMC and E143 results for the neutron are evaluated from the difference of deuteron and proton data; the E142 results were obtained with a polarised ³He target. Only statistical errors are shown with the data points. As an example, the SMC systematic error is indicated by the shaded area. References: E142—P.L. Anthony et al., Phys. Rev. Lett. 71, 959 (1993); E143—K. Abe et al., Phys. Rev. Lett. 75, 25 (1995); SMC—D. Adams et al., Phys. Lett. B357, 248 (1995). (Courtesy of R. Voss, 1996.)

errors are shown with the data points. As an example, the SMC systematic error is indicated by the shaded area. References: **E80**—M.J. Alguard *et al.*, Phys. Rev. Lett. **37**, 1261 (1976); ibid. **41**, 70 (1978); **E130**—G. Baum *et al.*, Phys. Rev. Lett. **51**, 1135 (1983); **E143**—K. Abe *et al.*, Phys. Rev. Lett. **74**, 346 (1995); **EMC**—J. Ashman *et al.*, Nucl. Phys. **B328**, 1 (1989); **SMC**—D. Adams *et al.*, Phys. Lett. **B329**, 399 (1994) **B339**, 332 (1994) (E). In this plot, the E80, E130, and EMC data have been reevaluated using up-to-date parametrizations of F_2^p and $R = \sigma_L/\sigma_T$. (Courtesy of R. Voss, 1996.)

Jet Production in pp and $\bar{p}p$ Interactions

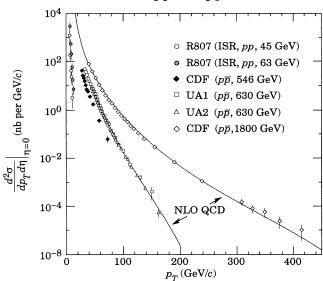

Figure 36.7: Differential cross sections for observation of a single jet of pseudorapidity $\eta=0$ as a function of the jet transverse momentum. CDF—F. Abe *et al.*, Phys. Rev. Lett. **70**, 1376 (1993); UA1—G. Arnison *et al.*, Phys. Lett. B172, 461 (1986); UA2—J. Alitti *et al.*, Phys. Lett. B257, 232 (1991); R807—T. Akesson *et al.*, Phys. Lett. B123, 133 (1983). Next-to-leading order QCD curves are shown for 630 GeV and 1800 GeV. (Courtesy of S. Geer, FNAL, 1995.)

Direct γ Production in $\overline{p}p$ Interactions

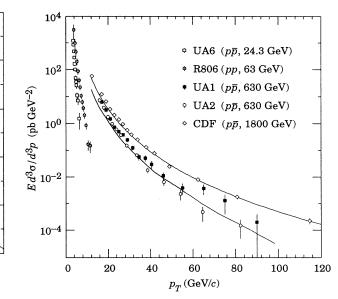

Figure 36.8: Differential cross sections for observation of a single photon of pseudorapidity $\eta=0$ as a function of the photon transverse momentum R806—E. Anassontzis et al., Z. Phys. C13, 277 (1982); UA6—A. Bernasconi et al., Phys. Lett. B206, 163 (1988); UA1—C. Albajar et al., Phys. Lett. B209, 385 (1988); UA2—J. Alitti et al., Phys. Lett. B288, 386 (1992); CDF—F. Abc et al., Phys. Rev. Lett. 73, 2662 (1994). Next-to-leading order QCD curves are shown for 630 GeV and 1800 GeV. (Courtesy of S. Geer, FNAL, 1995.)

Pseudorapidity Distributions in $\overline{p}p$ Interactions

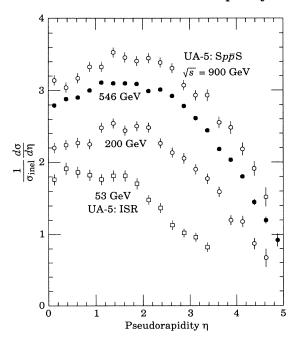

Figure 36.9: Charge particle pseudorapidity distributions in $p\overline{p}$ collisions for 53 GeV $\leq \sqrt{s} \leq$ 900 GeV. The number per pseudorapidity interval is about 10% higher if the rate is normalized excluding singly diffractive events rather than to the total inelastic rate. $Sp\overline{p}S$ data are from G.J. Alner et al., Z. Phys. C33, 1 (1986), and ISR data are from K. Alpgård et al., Phys. Lett. 112B, 193 (1982). CDF nonsingle-diffractive results at $\sqrt{s}=630$ and 1800 GeV are given in F. Abe et al., Phys. Rev. D41, 2330 (1990). (Courtesy of D.R. Ward, Cambridge Univ., 1991.)

Average Hadron Multiplicities in Hadronic e^+e^- Annihilation Events

Table 36.1: Average hadron multiplicity per e^+e^- annihilation event at $\sqrt{s}\approx 10$, 29–35, and 91 GeV. The rates given include decay products from resonances with $c\tau<10$ cm, and include charge conjugated states. (Updated July 1995 by O. Biebel.)

All average multiplicites are per hadronic e^+e^- annihilation event.

- (a) $B(D_s \to \eta \pi, \eta' \pi)$ has been used (RPP 1994).
- (b) The Standard Model $B(Z \to b\overline{b}) = 0.217$ was used.
- (c) $x_p = p/p_{\text{beam}} > 0.1$ only.
- (d) Extrapolation to the unobserved region using the shape predicted by JETSET.
- (e) Any charge state (i.e., B_d^* , B_u^* , or B_s^*).
- (f) $B(Z \rightarrow hadrons) = 0.699$ has been used (RPP 1994).
- (g) $x_E = E[K_2^*(1430)0]/E_{\text{beam}} < 0.3 \text{ only}$
- (h) Any charge state (i.e., B_d^{**} , B_u^{**} , or B_s^{**}).
- (i) The value was taken from the cross section of the $\Lambda_c^+ \to p\pi K$, assuming the branching fraction to be $(3.2\pm0.7)\%$ (RPP 1992).

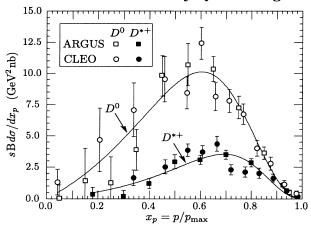

Figure 36.12: Fragmentation into $p\overline{p}$ in e^+e^- annihilations: Inclusive cross sections $(1/\sigma_{\rm had})(d\sigma/dx)$, with $x=p/p_{\rm beam}$. The indicated errors are statistical and systematic errors added in quadrature.

 \triangle : rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8%. This rate is obtained from the measured \overline{p} rate by scaling with a factor of two: **ARGUS**—H. Albrecht *et al.*, Z. Phys. **C44**, 547 (1989).

 \blacksquare : rate at $\sqrt{s}=29$ GeV: **TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988).

 \bigcirc : rate for hadronic decays of the Z at $\sqrt{s}=91.2$ GeV: **ALEPH**—D. Buskulic *et al.*, Z. Phys. **C66**, 355 (1995). **DELPHI**—P. Abreu *et al.*, Nucl. Phys. **B444**, 3 (1995). **OPAL**—R. Akers *et al.*, Z. Phys. **C63**, 181 (1994). (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1995.)

Heavy Quark Fragmentation in e^+e^- Annihilation

Average e^+e^- , pp, and $\bar{p}p$ Multiplicity

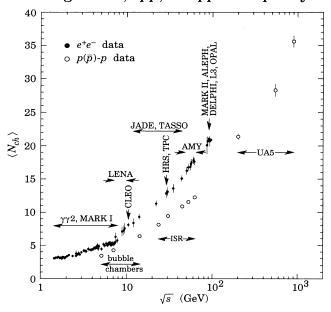

Figure 36.14: Average multiplicity as a a function of \sqrt{s} for e^+e^- and $p\overline{p}$ annihilations and and pp collisions. The indicated errors are statistical and systematic errors added in quadrature, except when no systematic errors are given.

 e^+e^- : All measurements include contributions from K_S^0 and Λ decays. The $\gamma\gamma 2$ and MARK I measurements contain a systematic 5% error. The five points at the Z resonance have been spread horizontally for clarity: **OPAL**—P.D. Acton *et al.*, Z. Phys. **C53**, 539 (1992) and references therein, R. Akers *et al.*, Z. Phys. **C68**, 203 (1995); **ALEPH**—D. Buskulic *et al.*, Z. Phys. C, CERN PPE/95-82.

 $p(\overline{p})$: The values measured by UA5 exclude single diffractive dissociation: J. Benecke *et al.* (bubble chamber), Nucl. Phys. **B76**, 29 (1976), W.M. Morse *et al.* (bubble chamber), Phys. Rev. **D15**, 66 (1977); **ISR**—A. Breakstone *et al.*, Phys. Rev. **D30**, 528 (1984); **UA5**—G.J. Alner *et al.*, Phys. Lett. **167B**, 476 (1986), Ansorge *et al.*, Z. Phys. **C43**, 357 (1989). (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1994.)

Figure 36.13: Heavy quark fragmentation: Shown are the CLEO—D. Bortoletto et~al., Phys. Rev. D37, 1719 (1988) and ARGUS—H. Albrecht et~al., Z. Phys. C52, 353 (1991) inclusive cross sections ($s~B~d\sigma/dx_p$, with $x_p=p/p_{\rm max}$) for the production of pseudoscalar D^0 and vector D^{*+} in e^+e^- annihilations at $\sqrt{s}\sim 10~{\rm GeV}$. For the D^0 , B is the branching ratio for $D^0\to K^-\pi^+$, while in the D^{*+} case B is the product branching ratio for $D^{*+}\to D^0\pi^+$ followed by $D^0\to K^-\pi^+$. These inclusive spectra have not been corrected for cascades from higher states, nor for radiative effects. Many functional forms have been suggested to describe these "hard" spectra, characteristic of charmed particles produced in e^+e^- annihilations. The parameterization given by Peterson e^+e^- (Phys. Rev. D27, 105, (1983)) in terms of just one variable ϵ_p has found the most use:

$$\frac{dN}{dx_p} = \frac{1}{x_p[1 - (1/x_p) - \epsilon_p/(1 - x_p)]^2} \ .$$

Fits to the combined CLEO and ARGUS D^0 and D^{*+} data give $\epsilon_p(D^0)=0.135\pm0.010$ and $\epsilon_p(D^*)=0.078\pm0.008$; these are indicated by the solid curves.

Spin-dependent effects have been observed in, e.g., the polarization of D^{*+} mesons as a function of x_p . Recent measurements of ϵ_p for D^{**} and D_{sJ} mesons by **CLEO**—J. Alexander et~al., Phys. Lett. **B303**, 377 (1993) and **ARGUS**—H. Albrecht et~al., Phys. Lett. **B221**, 422 (1989) and Phys. Lett. **B232**, 398, (1989) also indicate that the fragmentation functions of such orbitally excited charmed mesons are distinctly harder than for D or D^* mesons. How much of this is a mass effect and how much is truly a spin effect has not yet been fully determined. (Courtesy of D. Besson, Univ. of Kansas, 1994.)

Annihilation Cross Section Near M_Z

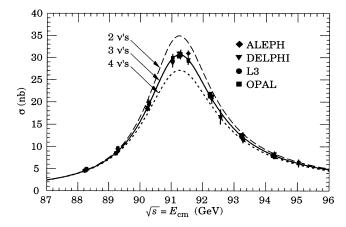

Figure 36.15: Data from the ALEPH, DELPHI, L3, and OPAL Collaborations for the cross section in e^+e^- annihilation into hadronic final states as a function of c.m. energy near the Z. LEP detectors obtained data at the same energies; some of the points are obscured by overlap. The curves show the predictions of the Standard Model with three species (solid curve) and four species (dashed curve) of light neutrinos. The asymmetry of the curves is produced by initial-state radiation. References:

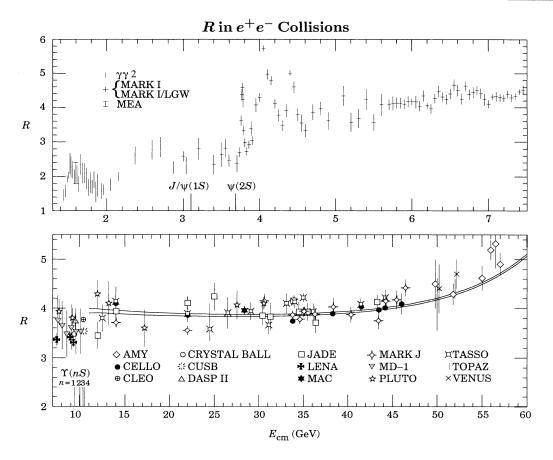

Figure 36.16: Selected measurements of $R \equiv \sigma(e^+e^- \to \text{hadrons})/\sigma(e^+e^- \to \mu^+\mu^-)$, where the annihilation in the numerator proceeds via one photon or via the Z. Measurements in the vicinity of the Z mass are shown in the following figure. The denominator is the calculated QED single-photon process; see the section on Cross-Section Formulae for Specific Processes. Radiative corrections and, where important, corrections for two-photon processes and τ production have been made. Note that the ADONE data $(\gamma\gamma^2)$ and MEA is for ≥ 3 hadrons. The points in the $\psi(3770)$ region are from the MARK I—Lead Glass Wall experiment. To preserve clarity only a representative subset of the available measurements is shown—references to additional data are included below. Also for clarity, some points have been combined or shifted slightly (<4%) in $E_{\rm cm}$, and some points with low statistical significance have been omitted. Systematic normalization errors are not included; they range from $\sim 5-20\%$, depending on experiment. We caution that especially the older experiments tend to have large normalization uncertainties. Note the suppressed zero. The horizontal extent of the plot symbols has no significance. The positions of the $J/\psi(1S)$, $\psi(2S)$, and the four lowest Υ vector-meson resonances are indicated. Two curves are overlaid for $E_{\rm cm} > 11$ GeV, showing the theoretical prediction for R, including higher order QCD [M. Dine and J. Sapirstein, Phys. Rev. Lett. 43, 668 (1979)] and electroweak corrections. The Λ values are for 5 flavors in the $\overline{\rm MS}$ scheme and are $\Lambda_{\rm MS}^{(5)} = 60$ MeV (lower curve) and $\Lambda_{\rm MS}^{(5)} = 250$ MeV (upper curve). (Courtesy of F. Porter, 1992.) References (including several references to data not appearing in the figure and some references to preliminary data):

Table 36.2: Regge theory provides a simple and compact description of total cross sections (A. Donnachie and P.V. Landshoff, Phys. Lett. B296, 227 (1992)): it is sufficient to write $\sigma_{\text{tot}} = X \, s^{\varepsilon} + Y \, s^{-\eta}$, where the first term arises from pomeron exchange and the second from ρ , ω , f, and a exchange. Simultaneous fits are shown below for groups of reactions within which ε and η have the same values, and $X_{ab} = X_{\overline{a}b}$. As can be seen from Fig. 36.17, the fitted exponents are consistent with having the same values for all reactions. The fitted functions are shown in the figures, along with the correlated one-standard-deviation error bands which, when the reduced χ^2 is greater than one, include a scale factor that is defined as the square root of the reduced χ^2 . Vertical arrows indicate lower limits on the momentum range used in the fits (these momenta are also given in the table). Curves and error bands are extrapolated to lower momenta; the user may decide on the range of applicability. Data used were extracted from the CS database of the Particle Physics Data System (PPDS), accessible through the WWW at http://pdg.lbl.gov/. Computer-readable data files are also available through http://pdg.lbl.gov/. (Courtesy of V.V. Ezhela, S.B. Lugovsky, and N.P. Tkachenko, COMPAS Group, IHEP, Protvino.)

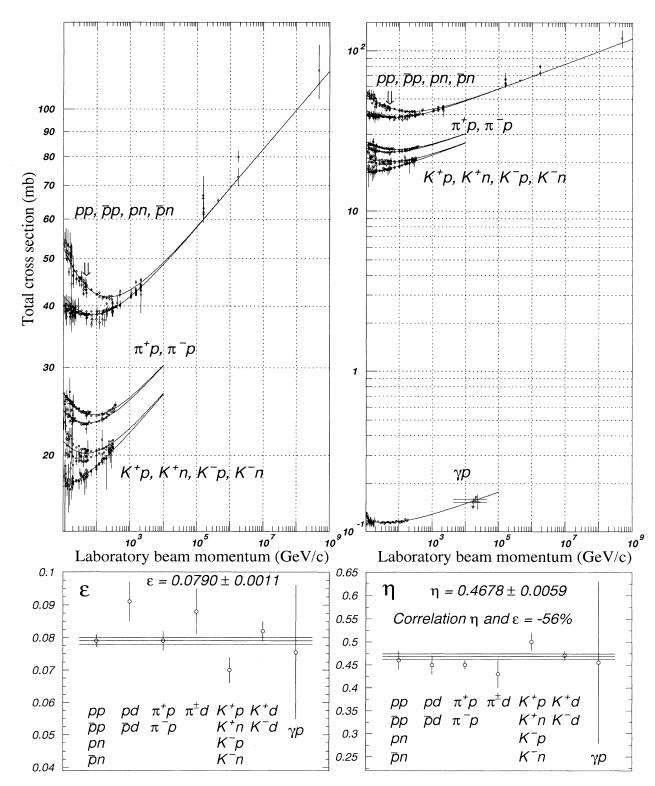

Figure 36.17: Summary of hadronic and γp total cross sections (top), and fit results to exponents for cross sections. (Courtesy of the COMPAS Group, IHEP, Protvino, Russia, 1996.)

- FISCHBACH 94 report < 8 × 10 With unknown CL. We report Baysian CL used elsewhere in these Listings and described in the Statistics section.
 CHERNIKOV 92 measures the photon mass at 1.24 K, following a theoretical suggestion that electromagnetic gauge invariance might break down at some low critical temperature. See the erratum for a correction, included here, to the published result.
 RYAN 85 measures the photon mass at 1.36 K (see the footnote to CHERNIKOV 92).
- ACHIBISOV 76 depends in critical way on assumptions such as applicability of virial theorem. Some of the arguments given only in unpublished references.

 See criticism questioning the validity of these results in KROLL 71 and GOLDHABER 71.

$< 2 \times 10^{-32}$	COCCONI	88	TOF	resolution Pulsar $f_1 - f_2$ TOF

⁶ RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to disperis the coccount of the state of the coccount of the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.

7 See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAFFELT 94 note.

OMITTED FROM SUMMARY TABLE

graviton MASS

All of the following limits are obtained assuming Yukawa potential in weak field limit. VANDAM 70 argue that a massive field cannot approach general relativity in the zero-mass limit; however, see GOLD-HABER 74 and references therein. h_0 is the Hubble constant in units of 100 km s $^{-1}$ Mpc $^{-1}$.

<8 × 10 ⁴	HARE	73	2√ decav		

¹ DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity c (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor [spin 2]-biscalar theories.

W MASS

OUR FIT uses the W and Z mass, mass difference, and mass ratio mea-

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. Performing an overall fit (assuming the Standard Model) of published and unpublished (CDF and DØ) collider results ($M_W=80.33\pm$ 0.15 GeV), of the νN results $(1-M_W^2/M_Z^2=0.2257\pm0.0047)$ and of published and unpublished LEP and SLD preliminary electroweak results (as of end of March 1996), the W mass is fitted to be $M_W=(80.350\pm0.0016)$ $0.042^{+0.016}_{-0.025}$) GeV (the second errors correspond to varying the Higgs mass in the interval 60-1000 GeV).

- 1 ABE 95P use 3268 $W\to \mu\nu_\mu$ events to find $M=80.310\pm0.205\pm0.130$ GeV and 5718 $W\to e\nu_e$ events to find $M=80.490\pm0.145\pm0.175$ GeV. The result given here combines these while accounting for correlated uncertainties.
- 2 ABE 90G result from $W\to e\nu$ is 79.91 \pm 0.35 \pm 0.24 \pm 0.19(scale) GeV and from $W\to \mu\nu$ is 79.90 \pm 0.53 \pm 0.32 \pm 0.08(scale) GeV.
- 3 ALITTI 92B result has two contributions to the systematic error (± 0.83); one (± 0.81) cancels in m_W/m_Z and one (± 0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.

Gauge & Higgs Boson Particle Listings

W

- 4 There are two contributions to the systematic error (±0.84): one (±0.81) which cancels in m_W/m_Z and one (±0.21) which is non-cancelling. These were added in quadrature.
- ⁵ ABE 891 systematic error dominated by the uncertainty in the absolute energy scale.
- ⁶ ALBAJAR 89 result is from a total sample of 299 $W \rightarrow e\nu$ events.
- ALBAJAR 89 result is from a total sample of 67 $W \rightarrow \mu\nu$ events.

⁸ ALBAJAR 89 result is from $W \to \tau \nu$ events. ⁹ There are two contributions to the systematic error (±1.4): one (±1.3) which cancels in m_W/m_Z and one (±0.5) which is non-cancelling. These were added in quadrature. $^{10}\,\mathrm{This}$ is enhanced subsample of 172 total events.

 $^{11}\, {\rm Using}\,\, W^\pm \to \,\, \mu^\pm \nu.$

W WIDTH

The CDF and DØ widths labelled "extracted value" are obtained by mea-The CPF and by which stabletic extracted value are obtained by linear suring $R = [\sigma(W)/\sigma(Z)] [\Gamma(W \to e\nu_e)]/(B(Z \to ee)\Gamma(W))$ where the bracketed quantities can be calculated with plausible reliability. $\Gamma(W)$ is then extracted by using a value of $B(Z \to ee)$ measured at LEP. The UA1 and UA2 widths used $R = [\sigma(W)/\sigma(Z)] [\Gamma(W \to e\nu_e)/\Gamma(Z \to ee)]$ $\Gamma(Z)/\Gamma(W)$ and the measured value of $\Gamma(Z)$. The Standard Model resolutions in 2.06.7 + 0.031/P(DS)EP.04) prediction is 2.067 \pm 0.021 (ROSNER 94).

- 13 ABACHI 950 measured $R=10.90\pm0.49$ and used the measured value B(Z $\to \ell\ell)=(3.367\pm0.006)\%$ from LEP.
- ¹⁴ ABE 95C use the tall of the transverse mass distribution of $W \to e \nu_e$ decays.
- $^{15}\,\mathrm{ABE}$ 95W measured R = 10.90 \pm 0.32 \pm 0.29. They use $m_{\ensuremath{W}}{=}80.23$ \pm 0.18 GeV, $\sigma(W)/\sigma(Z)=3.35\pm0.03,~\Gamma(W\to e\nu)=225.9\pm0.9~{\rm MeV},~\Gamma(Z\to e^+e^-)=83.98\pm0.18~{\rm MeV},~{\rm and}~\Gamma(Z)=2.4969\pm0.0038~{\rm GeV}.$ 16 ALITTI 92 measured $R=10.4^+0.7_-0.6_-10.0038_-$
- $O(lpha_S^2)$ calculations using $m_W=$ 80.14 \pm 0.27 GeV, and $m_Z=$ 91.175 \pm 0.021 GeV along with the corresponding value of $\sin^2\theta_W=0.274$. They use $\sigma(W)/\sigma(Z)=3.26\pm0.07\pm0.05$ and $\Gamma(Z)=2.487\pm0.010$ GeV. 17 ALBAJAR 91 measured $R=9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using $m_W=80.18\pm0.28$ GeV and $m_Z=91.172\pm0.031$ GeV

- along with $\sin^2\!\theta_W=0.2322\pm0.0014$. They use $\sigma(W)/\sigma(Z)=3.23\pm0.05$ and $\Gamma(Z)=2.498\pm0.020$ GeV.
- = 2.498 \pm 0.020 GeV. 18 ABE 92I report 1216 \pm 38 $^{+27}_{-31}$ $W \rightarrow \mu \nu$ and 106 \pm 10 $^{+0.2}_{-1}$ $Z \rightarrow \mu^+ \mu^-$ events which are combined with 2426 $W \rightarrow e \nu$ events of ABE 91C to derive the ratio σ_W B($W \rightarrow e \nu$) $\ell \nu)/\sigma_Z$ B(Z \to $\ell^+\ell^-)=$ 10.0 \pm 0.6 \pm 0.4. Finally the value of $\Gamma(Z)$ measured by LEP 92 is used to extract $\Gamma(W)$.
- ¹⁹ ABE 90 extract $\Gamma(W)$. $= 2.19 \pm 0.20$ by using the value $\Gamma(Z) = 2.57 \pm 0.07$ GeV. However, in ABE 91c they update their analysis with a new LEP value $\Gamma(Z) = 2.496 \pm 0.016$; the value $\Gamma(W) = 2.12 \pm 0.20$ above reflects this update. They measured $R = 10.2 \pm 0.8 \pm 0.4$, assumed $\sin^2\theta_W = 0.229 \pm 0.007$, and took predicted values $\sigma(W)/\sigma(Z) = 3.23 \pm 0.03$ and $\Gamma(W \rightarrow ev)/\Gamma(Z \rightarrow ee) = 2.70 \pm 0.02$. This yields $\Gamma(W)/\Gamma(Z) = 0.02$ 0.85 \pm 0.08. The quoted error for $\Gamma(W)$ includes systematic uncertainties. $E_{\rm cm}^{p\overline{p}}=1800$
- $\rm ^{20}\,GeV.$ ALITTI 90C used the same technique as described for ABE 90. They measured R = $9.38^{+0.82}_{-0.72}\pm0.25$, obtained $\Gamma(W)/\Gamma(Z)=0.902\pm0.074\pm0.024$. Using $\Gamma(Z)=2.546\pm0.032$ GeV, they obtained the $\Gamma(W)$ value quoted above and the limits $\Gamma(W)$ $< 2.56 (2.64) \text{ GeV at the } 90\% (95\%) \text{ CL. } E_{\text{CM}}^{p\overline{p}} = 546,630 \text{ GeV}.$
- 21 ALBAJAR 89 result is from a total sample of 299 $W\to e\nu$ events. 22 If systematic error is neglected, result is 2.7 $^{+1.4}_{-1.5}$ GeV. This is enhanced subsample of

W ANOMALOUS MAGNETIC MOMENT (Δκ)

The full magnetic moment is given by $\mu_W=e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa=1$ and $\lambda=0$. Some papers have defined $\Delta\kappa=1-\kappa$ and assume that $\lambda=0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter Λ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the W boson becomes manifest.

- 23 ABE 95G report $-1.3 < \kappa < 3.2$ for $\lambda=0$ and $-0.7 < \lambda < 0.7$ for $\kappa=1$ in $p\,\overline{p} \to e\,\nu_e\,\gamma\, X$ and $\mu \nu_{\mu} \gamma {\rm X}$ at $\sqrt{s}=$ 1800 GeV.
- 24 ALITTI 92C measure $\kappa=1+\frac{2.6}{2.2}$ and $\lambda=0+\frac{1.7}{1.8}$ in $p\overline{p}\to e\nu\gamma+$ X at $\sqrt{s}=630$ GeV. At 95%CL they report $-3.5<\kappa<5.9$ and $-3.6<\lambda<3.5$. 25 SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4<\kappa<3.7$ at 96%CL and $-3.1<\kappa<4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative W decay.
- ²⁶ SAMUEL 91 use preliminary CDF data for $p\overline{p}\to W\gamma X$ to obtain $-11.3 \le \Delta\kappa \le 10.9$. Note that their $\kappa=1-\Delta\kappa$.
- 27 GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta\kappa\lesssim 65~(M_W^2/\Lambda^2).$
- 28 GROTCH 87 finds the limit $-37~<~\Delta\kappa~<73.5$ (90% CL) from the experimental limits on $e^+e^- \to \nu \overline{\nu} \gamma$ assuming three neutrino generations and $-19.5 < \Delta \kappa < 56$ for four generations. Note their $\Delta \kappa$ has the opposite sign as our definition.
- 29 VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa| < 33$ (m_W/Λ). In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine $\Delta\kappa$.
- the Standard Model to determine $\Delta\kappa$. 30 GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole (λ) moments $1.05 > \Delta\kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda=0$. 31 SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa|\lesssim 190$
- $(m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa|\lesssim 2.2/{
 m ln}(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ho parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa|\lesssim 150~(m_W/\Lambda)^4$ if $|\Delta\kappa|\ll$
- 32 HERZOG 84 consider the contribution of W-boson to muon magnetic moment including anomalous coupling of W W γ . Obtain a limit $-1~<~\Delta\kappa~<3$ for $\Lambda~\gtrsim~1$ TeV.

W+ DECAY MODES

W- modes are charge conjugates of the modes below.

	Mode	F	Fraction (Γ_i/Γ)			
Γ ₁	$\ell^+ \nu$	[a]	(10.8±	0.4) %		
Γ_2	$e^+ \nu$		$(10.8 \pm$	0.4) %		
Γ_3	$\mu^+ \nu$		$(10.4 \pm$	0.6) %		
Γ_4	$\tau^+ \nu$		$(10.9 \pm$	1.0) %		
Γ_5	hadrons		$(67.9 \pm$	1.5) %		
Γ_6	$\pi^+\gamma$		< 5	$\times 10^{-4}$	95%	

[a] ℓ indicates each type of lepton $(e, \mu, \text{ and } \tau)$, not sum over them.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 8 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 1.7 for 5 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{ ext{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

W BRANCHING RATIOS

 $\Gamma(\ell^+\nu)/\Gamma_{
m total}$ ℓ indicates average over e, μ , and au modes, not sum over modes.

Currently only e and μ data enter this average because there are no absolute τ data, only the τ/e ratio.

34 ABE 95w result is from a measurement of $\sigma B(W \to e \nu)/\sigma B(Z \to e^+e^-) = 10.90 \pm 0.32 \pm 0.29$, the theoretical prediction for the cross section ratio, the experimental knowledge of $\Gamma(Z \rightarrow e^+e^-) = 83.98 \pm 0.18$ MeV, and $\Gamma(Z) = 2.4969 \pm 0.0038$.

knowledge of f ($Z \rightarrow e^+e^-$) = 83.98 ± 0.18 MeV, and 1(Z) = 2.4909 ± 0.0050. 35 The first error was obtained by adding the statistical and systematic experimental uncertainties in quadrature. The second error reflects the dependence on theoretical prediction of total W cross section: $\sigma(546 \text{ GeV}) = 4.7 \cdot 1.4^{\circ} \text{ nb}$ and $\sigma(630 \text{ GeV}) = 5.8 \cdot 1.8^{\circ} \text{ nb}$.

See ALTARELLI 858. 36 ABE 91C result is from a measurement of $\sigma B(W \to e \nu)/\sigma B(Z \to e^+e^-)$, the theoretical prediction for the cross section ratio, and the experimental knowledge of $\Gamma(Z \rightarrow e^+e^-)/\Gamma(Z \rightarrow all).$

THE Z BOSON

(by C. Caso, Univ. di Genova and A. Gurtu, Tata Inst.)

Precision measurements at the Z-boson resonance using electron-positron colliding beams began in 1989 at the SLC and at LEP. During 1989–95, the four CERN experiments have made high-statistics studies of the Z. The availability of longitudinally polarized electron beams at the SLC since 1993 has enabled a precision determination of the effective electroweak mixing angle $\sin^2 \overline{\theta}_W$ that is competitive with the CERN results on this parameter.

The Z-boson properties reported in this section may broadly be categorized as:

- The standard 'lineshape' parameters of the Z consisting of its mass, M_Z , its total width, Γ_Z , and its partial decay widths, $\Gamma(\text{hadrons})$ and $\Gamma(\ell \bar{\ell})$ where $\ell = e, \mu, \tau, \nu$;
- The b- and c-quark-related partial widths and charge asymmetries which require special techniques;
- Determination of rare Z decay modes and the search for modes that violate known conservation laws.

For the lineshape-related Z properties there are no new published LEP results after those included in the 1994 edition of this compilation. The reason for this is the identification in mid 1995 of a new systematic effect which shifts the LEP energy by a few MeV. This is due to a drift of the dipole field in the LEP magnets caused by parasitic currents generated by electrically powered trains in the Geneva area. The LEP Energy Working Group is studying the implications of this for the Z-lineshape properties which would be obtained after analysis of the high statistics 1993–95 data. The main consequence of this effect is expected to be in the determination of the Z mass.

Details on Z-parameter determination and the study of $Z\to b\bar{b}, c\bar{c}$ at LEP and SLC are given in this note.

The standard 'lineshape' parameters of the Z are determined with increasing precision from an analysis of the production cross sections of these final states in e^+e^- collisions. The $Z\to \nu\overline{\nu}(\gamma)$ state is identified directly by detecting single photon production and indirectly by subtracting the visible partial widths from the total width. Inclusion in this analysis of the forward-backward asymmetry of charged leptons, $A_{FB}^{(0,\ell)}$, of the τ polarization, $P(\tau)$, and its forward-backward asymmetry, $P(\tau)^{fb}$, enables the separate determination of the effective vector (\overline{g}_V) and axial vector (\overline{g}_A) couplings of the Z to these leptons and the ratio $(\overline{g}_V/\overline{g}_A)$ which is related to the effective electroweak mixing angle $\sin^2 \overline{\theta}_W$ (see the Standard Model review).

Determination of the b- and c-quark-related partial widths and charge asymmetries involves tagging the b and c quarks. Traditionally this was done by requiring the presence of a prompt lepton in the event with high momentum and high

transverse momentum (with respect to the accompanying jet). Precision vertex measurement with silicon detectors has enabled one to do impact parameter and lifetime tagging. Neural-network techniques have also been used to classify events as b or non-b on a statistical basis using event-shape variables. Finally, the presence of a charmed meson (D/D^*) has been used to tag heavy quarks.

Z-parameter determination

LEP is run at a few energy points on and around the Z mass constituting an energy 'scan.' The shape of the cross-section variation around the Z peak can be described by a Breit-Wigner ansatz with an energy-dependent total width [1]. The three main properties of this distribution, viz., the position of the peak, the width of the distribution, and the height of the peak, determine respectively the values of M_Z , Γ_Z , and $\Gamma(e^+e^-) \times$ $\Gamma(f\overline{f})$, where $\Gamma(e^+e^-)$ and $\Gamma(f\overline{f})$ are the electron and fermion partial widths of the Z. The quantitative determination of these parameters is done by writing analytic expressions for these cross sections in terms of the parameters and fitting the calculated cross sections to the measured ones by varying these parameters, taking properly into account all the errors. Singlephoton exchange (σ_{γ}^0) and γ -Z interference $(\sigma_{\gamma Z}^0)$ are included, and the large (\sim 25 %) initial-state radiation (ISR) effects are taken into account by convoluting the analytic expressions over a 'Radiator Function [1,2]' H(s,s'). Thus for the process $e^+e^- \to f\overline{f}$:

$$\sigma_f(s) = \int H(s, s') \ \sigma_f^0(s') \ ds' \tag{1}$$

$$\sigma_f^0(s) = \sigma_Z^0 + \sigma_\gamma^0 + \sigma_{\gamma Z}^0 \tag{2}$$

$$\sigma_{Z}^{0} = \frac{12\pi}{M_{Z}^{2}} \ \frac{\Gamma(e^{\pm}e^{-})\Gamma(f\overline{f})}{\Gamma_{Z}^{2}} \ \frac{s \ \Gamma_{Z}^{2}}{(s-M_{Z}^{2})^{2} \ + \ s^{2}\Gamma_{Z}^{2}/M_{Z}^{2}} \ (3)$$

$$\sigma_{\gamma}^{0} = \frac{4\pi\alpha^{2}(s)}{3s} Q_{f}^{2} N_{c}^{f} \tag{4}$$

$$\sigma^0_{\gamma Z} = -\; \frac{2\sqrt{2}\alpha(s)}{3}\;\; (Q_f G_F N_c^{\;f} g_{Ve} g_{Vf}) \label{eq:sigma_Z}$$

$$\times \frac{(s - M_Z^2)M_Z^2}{(s - M_Z^2)^2 + s^2\Gamma_Z^2/M_Z^2} \tag{5}$$

where Q_f is the charge of the fermion, $N_c^f = 3(1)$ for quark (lepton) and g_{Vf} is the neutral vector coupling of the Z to the fermion-antifermion pair $f\bar{f}$.

Since $\sigma_{\gamma Z}^0$ is expected to be much less than σ_Z^0 , the LEP collaborations have generally calculated the interference term in the framework of the Standard Model using the best known values of g_V . This fixing of $\sigma_{\gamma Z}^0$ leads to a tighter constraint on M_Z and consequently a smaller error on its fitted value.

Defining

$$A_f = 2 \frac{g_{Vf} \cdot g_{Af}}{(g_{Vf}^2 + g_{Af}^2)} \tag{6}$$

where g_{Af} is the neutral axial-vector coupling of the Z to $f\overline{f}$, the lowest-order expressions for the various lepton-related asymmetries on the Z pole are [3] $A_{FB}^{(0,\ell)}=(3/4)A_eA_f$, $P(\tau)=-A_{\tau}$,

 $P(\tau)^{fb}=-(3/4)A_e,~A_{LR}=A_e.$ The full analysis takes into account the energy dependence of the asymmetries. Experimentally A_{LR} is defined as $(\sigma_L-\sigma_R)/(\sigma_L+\sigma_R)$ where $\sigma_{L(R)}$ are the $e^+e^-\to Z$ production cross sections with left- (right)-handed electrons.

In terms of g_A and g_V , the partial decay width of the Z to $f\overline{f}$ can be written as

$$\Gamma(f\overline{f}) = \frac{G_F M_Z^3}{6\sqrt{2}\pi} (g_{Vf}^2 + g_{Af}^2) N_c^f (1 + \delta_{\text{QED}}) (1 + \delta_{\text{QCD}})$$
(7)

where $\delta_{\rm QED}=3\alpha Q_f^2/4\pi$ accounts for final-state photonic corrections and $\delta_{\rm QCD}=0$ for leptons and $\delta_{\rm QCD}=(\alpha_s/\pi)+1.409(\alpha_s/\pi)^2-12.77(\alpha_s/\pi)^3$ for quarks, α_s being the strong coupling constant at $\mu=M_Z$.

In the above framework, the QED radiative corrections have been explicitly taken into account by convoluting over the ISR and allowing the electromagnetic coupling constant to run [4]: $\alpha(s) = \alpha/(1 - \Delta \alpha)$. On the other hand, weak radiative corrections that depend upon the assumptions of the electroweak theory and on the values of the unknown M_{top} and M_{Higgs} are accounted for by absorbing them into the couplings, which are then called the effective couplings \bar{g}_V and \bar{g}_A (or alternatively the effective parameters of the * scheme of Kennedy and Lynn [5]).

S-matrix approach to the Z

While practically all experimental analyses of LEP/SLC data have followed the 'Breit-Wigner' approach described above, an alternative S-matrix-based analysis is also possible. The Z, like all unstable particles, is associated with a complex pole in the S matrix. The pole position is process independent and gauge invariant. The mass, \overline{M}_Z , and width, $\overline{\Gamma}_Z$, can be defined in terms of the pole in the energy plane via [6]

$$\overline{s} = \overline{M}_Z^2 - i\overline{M}_Z\overline{\Gamma}_Z \tag{8}$$

leading to the relations

$$\overline{M}_Z = M_Z / \sqrt{1 + \Gamma_Z^2 / M_Z^2} \tag{9}$$

$$\approx M_Z - 34 \; \mathrm{MeV}$$
 (10)

$$\overline{\Gamma}_Z = \Gamma_Z / \sqrt{1 + \Gamma_Z^2 / M_Z^2} \tag{11}$$

$$\approx \Gamma_Z - 0.9 \text{ MeV}$$
 (12)

Some authors [7] choose to define the Z mass and width via

$$\overline{s} = (\overline{M}_Z - \frac{i}{2}\overline{\Gamma}_Z)^2 \tag{13}$$

which yields $\overline{M}_Z \approx M_Z - 26$ MeV, $\overline{\Gamma}_Z \approx \Gamma_Z - 1.2$ MeV.

The L3 collaboration at LEP (ACCIARRI 96B) have analyzed their data using the S-matrix approach as defined in Eq. (8), in addition to the conventional one. They observe a downward shift in the Z mass as expected.

Handling the large-angle e^+e^- final state

Unlike other $f\overline{f}$ decay final states of the Z, the e^+e^- final state has a contribution not only from the s-channel but also

from the t-channel and s-t interference. The full amplitude is not amenable to fast calculation, which is essential if one has to carry out minimization fits within reasonable computer time. The usual procedure is to calculate the non-s channel part of the cross section separately using the Standard Model program ALIBABA [8] using the measured value of $M_{\rm top}$, and the 'central' value of $M_{\rm Higgs}$ (300 GeV) and add it to the s-channel cross section calculated as for other channels. This leads to two additional sources of error in the analysis: firstly, the theoretical calculation in ALIBABA itself is known to be accurate to $\sim 0.5\%$, and secondly, there is uncertainty due to the error on $M_{\rm top}$ and the unknown value of $M_{\rm Higgs}$ (60–1000 GeV). These additional errors are propagated into the analysis by including them in the systematic error on the e^+e^- final state

Errors due to uncertainty in LEP energy determination [9]

The systematic errors related to the LEP energy measurement can be classified as:

- The absolute energy scale error;
- Energy-point-to-energy-point errors due to the nonlinear response of the magnets to the exciting currents;
- Energy-point-to-energy-point errors due to possible higher-order effects in the relationship between the dipole field and beam energy;
- Energy reproducibility errors due to various unknown uncertainties in temperatures, tidal effects, corrector settings, RF status etc. Since one groups together data taken at 'nominally same' energies in different fills, it can be assumed that these errors are uncorrelated and are reduced by $\sqrt{N}_{\rm fill}$ where $\overline{N}_{\rm fill}$ is the (luminosity weighted) effective number of fills at a particular energy point.

At each energy point the last two errors can be summed into one point-to-point error.

$Choice\ of\ fit\ parameters$

The LEP collaborations have chosen the following primary set of parameters for fitting: M_Z , Γ_Z , $\sigma^0_{\rm hadron}$, $R({\rm lepton})$, $A^{(0,\ell)}_{FB}$, where $R({\rm lepton}) = \Gamma({\rm hadrons})/\Gamma({\rm lepton})$, $\sigma^0_{\rm hadron} = 12\pi\Gamma(e^+e^-)\Gamma({\rm hadrons})/M_Z^2\Gamma_Z^2$. With a knowledge of these fitted parameters and their covariance matrix, any other parameter can be derived. The main advantage of these parameters is that they form the least correlated set of parameters, so that it becomes easy to combine results from the different LEP experiments.

Thus, the most general fit carried out to cross section and asymmetry data determines the **nine parameters**: M_Z , Γ_Z , $\sigma^0_{\rm hadron}$, R(e), $R(\mu)$, $R(\tau)$, $A^{(0,e)}_{FB}$, $A^{(0,\mu)}_{FB}$, $A^{(0,\tau)}_{FB}$. Assumption of lepton universality leads to a **five-parameter fit** determining M_Z , Γ_Z , $\sigma^0_{\rm hadron}$, $R({\rm lepton})$, $A^{(0,\ell)}_{FB}$. The use of **only** cross-section data leads to six- or four-parameter fits if lepton

Gauge & Higgs Boson Particle Listings

Z

universality is or is not assumed, i.e., $A_{FB}^{(0,\ell)}$ values are not determined.

In order to determine the best values of the effective vector and axial vector couplings of the charged leptons to the Z, the above mentioned nine- and five-parameter fits are carried out with added constraints from the measured values of A_{τ} and A_e obtained from τ polarization studies at LEP and the determination of A_{LR} at SLC.

Combining results from the LEP and SLC experiments [10]

Each LEP experiment provides the values of the parameters mentioned above together with the full covariance matrix. The statistical and experimental systematic errors are assumed to be uncorrelated among the four experiments. The sources of **common** systematic errors are i) the LEP energy uncertainties, and ii) the effect of theoretical uncertainty in calculating the small-angle Bhabha cross section for luminosity determination and in estimating the non-s channel contribution to the large-angle Bhabha cross section. Using this information, a full covariance matrix, V, of all the input parameters is constructed and a combined parameter set is obtained by minimizing $\chi^2 = \Delta^T V^{-1} \Delta$, where Δ is the vector of residuals of the combined parameter set to the results of individual experiments.

Non-LEP measurement of a Z parameter, $(e.g., \Gamma(e^+e^-)$ from SLD) is included in the overall fit by calculating its value using the fit parameters and constraining it to the measurement.

Study of $Z \to b\overline{b}$ and $Z \to c\overline{c}$

In the sector of c- and b-physics the LEP experiments have measured the ratios of partial widths $R_b = \Gamma(Z \to b\bar{b})/\Gamma(Z \to \text{hadrons})$ and $R_c = \Gamma(Z \to c\bar{c})/\Gamma(Z \to \text{hadrons})$ and the forward-backward (charge) asymmetries $A_{FB}^{b\bar{b}}$ and $A_{FB}^{c\bar{c}}$. Several of the analyses have also determined other quantities, in particular the semileptonic branching ratios $B(b \to \ell)$ and $B(b \to c \to \ell^+)$ and the average $B^0 \overline{B}^0$ mixing parameter $\overline{\chi}$. The latter measurements do not concern properties of the Z boson and hence they are not covered in this section. However, they are correlated with the electroweak parameters, and since the mixture of b-hadrons is different from the one at the $\Upsilon(4S)$, their values might differ from those measured at the $\Upsilon(4S)$.

All the above quantities are correlated to each other since:

- Several analyses (for example the lepton fits) determine more than one parameter simultaneously;
- Some of the electroweak parameters depend explicitly on the values of other parameters (for example R_b depends on R_c);
- Common tagging and analysis techniques produce common systematic uncertainties.

The LEP Electroweak Heavy Flavour Working Group has then developed [11] a procedure for combining the measurements taking into account known sources of correlation. The combining procedure determines seven parameters: the four parameters of interest in the electroweak sector, R_b , R_c , $A_{FB}^{b\bar{b}}$, and $A_{FB}^{c\bar{c}}$ and, in addition, $B(b \to \ell)$, $B(b \to c \to \ell^+)$ and $\bar{\chi}$, to take into account their correlations with the electroweak parameters. Before the fit both the peak and off-peak asymmetries are translated to $\sqrt{s} = 91.26$ GeV using the predicted dependence from ZFITTER [2].

$Summary\ of\ the\ measurements\ and\ of\ the\ various\ kinds$ of analysis

The measurements of R_b and R_c fall into two classes. In the first, named single-tag measurement, a method for selecting b and c events is applied and the number of tagged events is counted. The second technique, named double-tag measurement, is based on the following principle: if the number of events with a single hemisphere tagged is N_t and with both hemispheres tagged is N_{tt} , then given a total number of N_{had} hadronic Z decays one has:

$$\frac{N_t}{2N_{\text{had}}} = \varepsilon_b R_b + \varepsilon_c R_c + \varepsilon_{uds} (1 - R_b - R_c)$$
 (14)

$$\frac{N_{tt}}{N_{\text{had}}} = \mathcal{C}_b \varepsilon_b^2 R_b + \varepsilon_c^2 R_c + \varepsilon_{uds}^2 (1 - R_b - R_c)$$
 (15)

where ε_b , ε_c , and ε_{uds} are the tagging efficiencies per hemisphere for b, c, and light quark events, and $\mathcal{C}_b \approx 1$ accounts for the fact that the tagging efficiencies between the hemispheres are correlated. Neglecting the c and uds background and the hemisphere correlation, these equations give:

$$\varepsilon_b = 2N_{tt}/N_t \tag{16}$$

$$R_b = N_t^2 / (4N_{tt}N_{\text{had}}) \tag{17}$$

The double-tagging method has thus the great advantage that the tagging efficiency is directly derived from the data, reducing the systematic error of the measurement. The backgrounds, dominated by $c\bar{c}$ events, obviously complicate this simple picture, and their level must still be inferred by other means. The rate of charm background in these analyses depends explicitly on the value of R_c . The correlations in the tagging efficiencies between the hemispheres (due for instance to correlations in momentum between the b-hadrons in the two hemispheres) are small but nevertheless lead to further systematic uncertainties.

The measurements in the b- and c-sector can be grouped in the following categories:

- Lepton fits which use hadronic events with one or more leptons in the final state. Each analysis usually gives several electroweak parameters chosen among: R_b , R_c , $A_{FB}^{b\bar{b}}$, $A_{FB}^{c\bar{c}}$, $B(b \rightarrow \ell)$, $B(b \to c \to \ell^+)$ and $\overline{\chi}$. The output parameters are then correlated. The dominant sources of systematics are due to lepton identification, to other semileptonic branching ratios and to the modelling of the semileptonic decay;
- ullet Event shape tag for R_b (both single and doubletagging have been used);
- Lifetime (and lepton) double-tagging measurements of R_b . These are the most precise measurements of R_b and obviously dominate the combined result. The main sources of systematics come from the assumed properties of the $c\overline{c}$ events and from estimating the hemisphere b-tagging efficiency cor-
- Measurements of $A_{FB}^{b\bar{b}}$ using lifetime tagged events with a measurement of the jet charge. Their contribution to the combined result has roughly the same weight as the lepton fits:
- Analyses with $D/D^{*\pm}$ to measure R_c . These measurements separate charmed hadrons coming from $b\bar{b}$ and $c\bar{c}$ decays on a statistical basis; thus R_c depends on properties of $b\bar{b}$ events but not on the
- Analyses with $D^{*\pm}$ to measure simultaneously $A_{FB}^{b\bar{b}}$ and $A_{FB}^{c\bar{c}}$.

Averaging procedure

All the measurements are provided by the LEP Collaborations in the form of tables with a detailed breakdown of the systematic errors of each measurement and its dependence on other electroweak parameters.

The average proceeds via the following steps:

- Define and propagate a consistent set of external inputs such as branching ratios, hadron lifetimes, fragmentation models etc. All the measurements are also consistently checked to ensure that all use a common set of assumptions (for instance for the lifetime/jet-charge measurements of asymmetries, where the QCD effects are already included as an inherent part of the analysis, a QCD correction is subtracted before combining);
- Form the full (statistical and systematic) covariance matrix of the measurements. The systematic correlations between different analyses are calculated from the detailed error breakdown in the measurement tables. The correlations relating several measurements made by the same analysis are also considered;

• Take into account any explicit dependence of a measurement on the other electroweak parameters. As an example of this dependence we illustrate the case of the double-tag measurement of R_h , where c-quarks constitute the main background. The normalization of the charm contribution is not fixed by the data and the measurement of R_b depends on the assumed value of R_c , which can

$$R_b = R_b^{\text{meas}} + a(R_c) \frac{(R_c - R_c^{\text{used}})}{R_c} , \qquad (18)$$

where R_b^{meas} is the result of the analysis which assumed a value of $R_c = R_c^{\text{used}}$ and $a(R_c)$ is the constant which gives the dependence on R_c . It is worth noting that the combining procedure shows that the only significant correlation between any of the resulting electroweak parameters turns out to be just between R_b and R_c . With the data contained in the present Listing the correlation coefficient between these two variables amounts to -0.39;

• Perform a χ^2 minimization with respect to the combined electroweak parameters.

After the fit the average peak asymmetries $A_{FB}^{c\bar{c}}$ and $A_{FB}^{b\bar{b}}$ are corrected for the energy shift and for QED, QCD, γ exchange, and γZ interference effects to obtain the corresponding pole asymmetries $A_{FB}^{0,c}$ and $A_{FB}^{0,b}$. A small correction is also applied to both R_b and R_c to account for the contribution of γ exchange.

Z MASS

The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. We believe that this set is the most free of correlations. Common systematic errors are taken into account. For more details, see the 'Note on the Z Boson,'

The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma-Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted $\it Z$ mass. See ACCIARRI 968 and ADRIANI 93H for a detailed investigation of both

A new source of LEP energy variation was discovered in mid 1995: an energy change of a few MeV is correlated with the passage of a train on nearby railway tracks. The LEP energy working group is studying the implications of this effect for the high statistics data recorded since 1993. The main consequence of this is expected to be a shift in the overall LEP energy values leading to a corresponding shift in the value of m_Z . The LEP collaborations have consequently deferred publication of their results on Z lineshape and lepton forward-backward asymmetries based on 1993 and later data.

 7 BUSKULIC 93J supersedes DECAMP 92B. The error includes 6 MeV due to the uncertainty in LEP energy calibration.
- ⁸ The LEP 93 error due to the experiments is 4 MeV and the uncertainty due to the absolute LEP energy scale is 6 MeV.
- ⁹ QUAST 93 is a combined analysis of LEP results as of Feb. 1993. A common systematic error of 6 MeV is taken into account.

- 10 Enters fit through W/Z mass ratio given in the W Particle Listings. The ALITTI 92B systematic error (± 0.93) has two contributions: one (± 0.92) cancels in m_W/m_Z and one (± 0.12) is noncancelling. These were added in quadrature.
- 11 MORI 89, ADACHI 90F use a Breit-Wigner resonance shape fit and combine their results with published data of PEP and PETRA.
- 12 First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
- 13 ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
- 14 Enters fit through Z-W mass difference given in the W Particle Listings.
- 15 ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.

- ²⁵ ANSARI 25 16 The second error of 4.5 MeV is due to a common LEP energy uncertainty.
 - The second error of 4.5 MeV is due to a common terrement and lepton forward-backward asymmetries in the framework of the S-matrix ansatz. The high-energy data constrains the γZ interference terms. The fitted width is expected to be 0.9 MeV less than that obtained using the standard Breit-Wigner parametrization (see 'Note on the Z Boson').
 - ¹⁸ The systematic error is from the uncertainty in the LEP energy calibration.
 - ¹⁹ The error in ADRIANI 93F includes 4 MeV due to the uncertainty in LEP energy calibra-
 - tion. 20 ADRIANI 93H use the S-matrix approach to determine the pole position for the Z boson. The fitted width is expected to be 0.9 MeV less than that obtained using the standard Breit-Wigner parametrization (see 'Note on the Z Boson').
 - 21 The error in BUSKULIC 93J includes 4 MeV due to the uncertainty in LEP energy
 - calibration.

 22 QUAST 93 is a combined analysis of LEP results as of Feb. 1993. A common systematic error of 4 MeV is taken into account
 - 23 ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction
 - error. 24 ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.
 - Example of 33 $Z\to e^+e^-$ events. ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z)<(1.09\pm0.07)\times\Gamma(W)$, CL = 90% or $\Gamma(Z)=(0.82^{+}0.19\pm0.06)\times\Gamma(W)$. Assuming Standard-Model value $\Gamma(W)=2.65$ GeV then gives $\Gamma(Z)<2.89\pm0.19$ or $=2.17^{+}0.50_{-}0.37\pm0.16$.

0.998±0.005 OUR FIT

 $\Gamma((u\overline{u}+c\overline{c})/2)/\Gamma(\text{hadrons})$

This quantity is the branching ratio of $Z \to$ "up-type" quarks to $Z \to$ hadrons. The values of $Z \to$ "up-type" and $Z \to$ "down-type" branchings are extracted from measurements of $\Gamma(\text{hadrons})$, and $\Gamma(Z \to \gamma + \text{jets})$ where γ is a high-energy (>5 GeV) isolated photon. As the experiments use slightly different values of M_Z , $\Gamma(\text{hadrons})$ and α_s in their extraction procedures, our average has to be taken with caution.

0.243 ± 0.022	⁵³ ADRIANI	93 L3	E ^{ee} _{CM} = 91.2 GeV

- 51 ABREU 95x use $M_Z=91.187\pm0.009$ GeV, $\Gamma({
 m hadrons})=1725\pm12$ MeV and $lpha_S$ 0.123 \pm 0.005. To obtain this branching ratio we divide their value of $C_{1/3}=1.62 {+0.24 \atop -0.17}$ by their value of (3 ${\it C}_{1/3}$ + 2 ${\it C}_{2/3}$) = 6.66 \pm 0.05.
- 52 ACTON 93F use the LEP 92 value of $\Gamma(\text{hadrons}) = 1740 \pm 12$ MeV and $\alpha_s =$ $0.122 + 0.006 \\ -0.005$
- $^{-0.005}$ ADRIANI 93 use $M_Z=91.181\pm0.022$ GeV, $\Gamma({\rm hadrons})=1742\pm19$ MeV and $\alpha_S=0.125\pm0.009$. To obtain this branching ratio we divide their value of $C_{1/3}=1.63\pm0.15$ by their value of (3 $C_{1/3}$ + 2 $C_{2/3}$) = 6.720 \pm 0.076.

 $R_c = \Gamma(c\overline{c})/\Gamma(\text{hadrons})$ OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson." As a cross check we have also performed a weighted average of the $R_{\mathcal{C}}$ measurements taking into account the various common systematic errors. Assuming that the smallest common systematic error is fully correlated, we obtain $R_{\it C} = 0.157 \pm 0.010$.

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. Combining published and unpublished preliminary LEP and SLD electroweak results (as of end of March 1996) yields $R_c=0.1598\pm0.0069$. This value appears to be 1.8 s.d. below its Standard Model prediction of 0.1725 for $m_t=175$ GeV and $M_H=300$ GeV.

- 54 ABREU 95D perform a maximum likelihood fit to the combined p and $p_{\mathcal{T}}$ distributions does not single and dilepton samples. The second error includes an uncertainty of ± 0.0124 due to models and branching ratios.
- 55 AKERS 950 use the presence of a $D^{*\pm}$ to tag $Z \to c \bar{c}$ with $D^* \to D^0 \pi$ and $D^0 \to D^0 \pi$ $K\pi$. They measure $P_c*\Gamma(c\overline{c})/\Gamma(\text{hadrons})$ to be $(1.006\pm0.055\pm0.061)\times10^{-3}$, where P_c is the product branching ratio $B(c \to D^+)B(D^+ \to D^0\pi)B(D^0 \to K\pi)$. Assuming that P_c remains unchanged with energy, they use its value $(7.1\pm0.5)\times 10^{-3}$ determined at CESR/PETRA to obtain $\Gamma(c7)/\Gamma(\text{hadrons})$. The second error of AKERS 950 includes an uncertainty of ± 0.011 from the uncertainty on P_c .
- 56 BUSKULIC 94G perform a simultaneous fit to the p and $p_{\mathcal{T}}$ spectra of both single and dilepton events

- 57 ABREU 93I assume that the D_{S} and charmed baryons are equally produced at LEP and
- 58 ABREU 920 use the neural network techinque to tag heavy flavour events among a ABNEO 920 use the feeting flework technique to day fleavy indoor events among a sample of 123k selected hadronic events. The systematic error consists of three parts: due to Monte Carlo (MC) parametrization (0.023), choice of MC model (0.033) and detector effects (0.009) added in quadrature.

$R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$

 Γ_{10}/Γ_{6}

OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson." As a cross check we have also performed a weighted average of the $R_{m{b}}$ measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. For $R_{\rm C}=0.158$ (as given by OUR FIT above), we obtain $R_{\rm b}=0.2213\pm$ 0.0019. For an expected Standard Model value of $R_C=0.172$, our weighted average gives $R_b=0.2200\pm0.0019$ while OUR FIT value becomes $R_b=0.2202\pm0.0018$.

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. Combining published and unpublished preliminary LEP and SLD electroweak results (as of end of March 1996) yields $R_{\rm b}=0.2211\pm0.0016$. This value appears to be 3.5 s.d. above its Standard Model prediction of 0.2155 for $m_t=175$ GeV and $M_H=300$ GeV (this apparent discrepancy has led to some speculation concerning new physics beyond the

- ⁵⁹ ABREU 96 obtain this result combining several analyses (double lifetime tag, mixed tag and multivariate analysis). This value is obtained assuming $R_c = \Gamma(c\,\overline{c})/\Gamma(\text{hadrons}) = 0.172$. For a value of R_c different from this by an amount ΔR_c the change in the value is given by $-0.087 \cdot \Delta R_c$.
- 60 ABREU 95D perform a maximum likelihood fit to the combined ρ and ρ_T distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0023 due to models and branching ratios.
- 61 AKERS 958 select events based on the lepton and/or vertex tag independently in each hemisphere. Comparing the numbers of single- and double-tagged events, they determine
- the b-tagging efficiency directly from data. ⁶² BUSKULIC 94G perform a simultaneous fit to the ρ and ρ_T spectra of both single and dilepton events.
- 63 ADRIANI 93E use a multidimensional analysis based on a neural network approach.
- 64 AKERS 93B use a simultaneous fit to single and dilepton events (electrons and muons) to tag $Z \to b \bar{b}$.
- 65 BUSKULIC 93M use a method which tags the $Z \to b\bar{b}$ decays through the lifetime of the produced heavy hadrons. The systematic error includes a contribution of ± 0.0016 due to the uncertainty of the charm partial width.
- 66 BUSKULIC 93N use event shape and high p_T lepton discriminators applied to both
- 67 JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of \geq 3 tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (± 0.014).
- 68 ABREU 950 obtain this result combining several analyses (double-lifetime tag and mixed tags). The second error contains an uncertainty of ± 0.0029 due to the total systematics and an uncertainty of ± 0.0019 due to the total systematics and an uncertainty of ± 0.0016 due to an 8% variation of $\Gamma(c\overline{c})/\Gamma(hadrons)$ around its Standard Model value (0.171 ± 0.014). Combining with their own lepton analysis, ABREU 950 obtain 0.2210 $\pm 0.0033 \pm 0.0003$ (models) ± 0.0014 [$\Gamma(c\overline{c})/\Gamma(hadrons)$].
- particle trajectories near the interaction point. The second error contains an uncertainty of ± 0.0012 due to an 8% variation of $\Gamma(c\,\overline{c})/\Gamma(\text{hadrons})$ around its Standard Model value (0.171 $\pm\,0.014)$.
- value (0.171 \pm 0.014). 70 AKERS 94D perform an analysis based on a "mixed tag" method (impact parameter and lepton tagging). The systematic error includes a contribution (\pm 0.007) due to the $\Gamma(c\bar{c})/\Gamma(\text{hadrons})$ uncertainty. 71 ACTON 931 use both electrons and muons to tag B semileptonic decays. The systematic
- error includes components due to b and c quark fragmentation uncertainties, decay branching ratios, and $\Gamma(c\overline{c})/\Gamma(\text{hadrons})$.
- 72 ACTON 93M tagged $Z \to b\bar{b}$ events using the impact parameter technique. 73 ABREU 92 result is from an indirect technique. They measure the lifetime τ_B , but use a world average of au_B independent of $\Gamma(b\,\overline{b})$ and compare to their $\Gamma(b\,\overline{b})$ dependent lifetime from a hadron sample.
- The ABREU 92K use boosted—sphericity technique to tag and enrich the $b \cdot \overline{b}$ content with a sample of 50k hadronic events. Most of the systematic error is from hadronization uncertainty.

Z HADRONIC POLE CROSS SECTION

This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit. (See the 'Note on the Z Boson.')

Z VECTOR COUPLINGS TO CHARGED LEPTONS

These quantities are the effective vector couplings of the Z to charged leptons. Their magnitude is derived from a measurement of the Z line-shape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e and A_τ , or ν_e scattering. The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e and A_τ measurements. See "Note on the Z boson" for details.

Within the current data set, the reason for the smallness of $g_L^{\mathcal{U}}$ compared to $g_V^{\mathcal{U}}$ and $g_V^{\mathcal{T}}$ is due to the large value of A_e which is heavily weighted by the SLD result. This large value of A_e leads to a large value of $g_V^{\mathcal{U}}$. Since $g_V^{\mathcal{U}}$ is obtained using the relation $A_{FB}^{\mathcal{U}} = 0.75 \times A_e \times A_{\mu}$, a large value of $g_V^{\mathcal{U}}$. Each storage value of $g_V^{\mathcal{U}}$. Concerning the r, its g_V gets mainly determined directly from A_r which is obtained from a measurement of the τ polarization (see "Note on the Z boson").

- 129 Using forward-backward lepton asymmetries.
- $^{130}\,\mathrm{The}\;\tau$ polarization result has been included.
- 131 QUAST 93 is a combined analysis of LEP results as of Feb. 1993. QUAST 93 use also the average LEP values for au polarization and the forward–backward au polarisation asymmetry. Assumes lepton universality.

Z AXIAL-VECTOR COUPLINGS TO CHARGED LEPTONS

These quantities are the effective axial-vector couplings of the \boldsymbol{Z} to charged leptons. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e and A_τ , or ν_e scattering. The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e and A_τ measurements. See "Note on the Z boson" for details

Z COUPLINGS TO NEUTRAL LEPTONS

These quantities are the effective couplings of the \boldsymbol{Z} to neutral leptons. $u_e\,e$ and $u_\mu\,e$ scattering results are combined with g_A^e and g_V^e measurements at the Z mass to obtain $g^{
u_e}$ and $g^{
u_\mu}$ following NOVIKOV 93c.

$g^{ u_{\mu}}$					
V ALUE	DOCUMENT ID		TECN	COMMENT	
0.502±0.017	138 VILAIN	94	CHM2	From ν_{ii} e scattering	

 138 VILAIN 94 derive this value from their measurement of the couplings $g_A^{~e\,
u_{\mu}}=-$ 0.503 \pm 0.017 and $g_V^{e\,
u\mu}=-$ 0.035 \pm 0.017 obtained from $\nu_\mu\,e$ scattering. We have re-evaluated this value using the current PDG values for g_A^e and g_V^e .

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the 'Note on the Z

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. An unpublished preliminary value of $A_{LR}~(=A_e)$ from SLD which includes all previous SLD data is 0.1551 \pm 0.0040 (combining statistical and systematic errors). If the ABE 94c value is replaced by this value, the average is 0.153 \pm 0.004 with no scale factor.

($0.37 \pm 0.23 \pm 0.21$	145	ABE	95L	SLD	Ecm = 91.26 GeV
($0.73 \pm 0.22 \pm 0.10$	146	ABE,K	95	SLD	$E_{\rm cm}^{ee} = 91.26 \; {\rm GeV}$

 145 ABE 95L tag $\it b$ and $\it c$ quarks through their semileptonic decays into electrons and muons.

A maximum likelihood fit is performed to extract A_b and A_c . 146 ABE,K 95 tag $Z \to c\overline{c}$ events using D^{*+} and D^+ meson production. To take care of the $b\overline{b}$ contamination in their analysis they use $A_b^D=0.64\pm0.11$ (which is A_b from D^*/D tagging). This is obtained by starting with a Standard Model value of 0.935, assigning it an estimated error of ±0.105 to cover LEP and SLD measurements, and finally taking into account $B \cdot \overline{B}$ mixing $(1-2\chi_{\rm mix}=0.72\pm0.09)$. Combining with ABE 95L they quote 0.59 ± 0.19 .

This quantity is directly extracted from a measurement of the left-right forwardbackward asymmetry in $b\overline{b}$ production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e .

VALUE	EVTS	DOCUMENT	D TECN	COMMENT	·

131+35+13		91.2	155 ARREII	95G DIPH

155 ABREU 95G require the presence of a high-momentum charged kaon or A^0 to tag the s quark. An unresolved s- and d-quark asymmetry of $(11.2\pm3.1\pm5.4)\%$ is obtained by tagging the presence of a high-energy neutron or neutral kaon in the hadron calorimeter.

$A_{FR}^{(0,c)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow c\overline{c}$

OUR FIT, which is obtained by a simultaneous fit to several c- and bquark measurements as explained in the "Note on the Z boson," refers to the Z pole asymmetry. As a cross check we have also performed a weighted average of the "near peak" measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. Applying to this combined "peak" measurement QCD, QED, and energy-dependence corrections, our weighted average gives a pole asymmetry of $(7.35 \pm 0.74)\%$

¹⁵⁶ ALEXANDER 96 tag heavy flavors using one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average $B^0 - \overline{B}^0$ mixing.

- 159 BUSKULIC 951 require the presence of a high momentum ${\it D^{*\pm}}$ to have an enriched
- 160 BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and
- 161 AKERS 93D identify the b and c decays using D^* .
- 162 ADRIANI 92D use both electron and muon semileptonic decays.
- 163 BUSKULIC 94J Identify the b and c decays using D^* . Repl. by BUSKULIC 95i.
- 164 ACTON 93K use the lepton tagging technique. Repl. by ALEXANDER 96.

$A_{ER}^{(0,b)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow b\overline{b}$

OUR FIT, which is obtained by a simultaneous fit to several c- and bquark measurements as explained in the "Note on the Z boson," refers to the Z pole asymmetry. As a cross check we have also performed a weighted average of the "near peak" measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. Applying to this combined "peak" measurement QCD, QED, and energy-dependence corrections, our weighted average gives a pole asymmetry of (9.96 \pm 0.39)%. For the jetcharge measurements (where the QCD corrections are already included since they represent an inherent part of the analysis), we subtract the QCD correction before combining.

165					

- $165\,\mathrm{ALEXANDER}$ 96 tag heavy flavors using one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average $B^0 - \overline{B}{}^0$ mixing.
- 166 ABREU 95E require the presence of a $D^{*\pm}$ to identify c and b quarks.
- 167 ABREU 95K identify c and b quarks using both electron and muon semileptonic decays. The systematic error includes an uncertainty of ± 0.3 due to the mixing correction ($X=0.115\pm0.011$).
- 168 ABREU 95K tag b quarks using lifetime; the quark charge is identified using jet charge. The systematic error includes an uncertainty of ± 0.3 due to the mixing correction ($\chi=$ 0.115 ± 0.011).
- 169 AKERS 95s tag b quarks using lifetime; the quark charge is measured using jet charge. These asymmetry values are obtained using $R_b = \Gamma(bb)/\Gamma(\text{hadrons}) = 0.216$. For a value of R_b different from this by an amount ΔR_b , the change in the asymmetry values of $R_b = \frac{1}{2} \frac{1}{2$ is given by $-K\Delta R_b$, where $K=0.082,\,0.471,\,{\rm and}\,\,0.855$ for \sqrt{s} values of 89.52, 91.25, and 92.94 GeV respectively.
- 170 ACCIARRI 94D use both electron and muon semileptonic decays.
- 171 BUSKULIC 94G perform a simultaneous fit to the p and $p_{\mathcal{T}}$ spectra of both single and
- 172 BUSKULIC 941 use the lifetime tag method to obtain a high purity sample of $Z \to b \, \overline{b}$ events and the hemisphere charge technique to obtain the jet charge. 173 AKERS 93D identify the b and c decays using D^* .
- 174 BUSKULIC 94G perform a high $p_{\mathcal{T}}$ lepton analysis using single- and double-tagged
- events.
 175 ACTON 93K use the lepton tagging technique. The systematic error includes the uncer-
- tainty on the mixing parameter. Replaced by ALEXANDER 96. ¹⁷⁶ QUAST 93 is a combined analysis of LEP results as of Feb. 1993.

¹⁵⁴ BACALA 89 systematic error is about 5%.

 $^{^{157}}$ ABREU 95E require the presence of a $D^{*\pm}$ to identify c and b quarks.

 $^{^{158}}$ ABREU 95K identify c and b quarks using both electron and muon semileptonic decays.

Ζ

- 177 B tagging via its semimuonic decay. Experimental value corrected using average LEP B^0 - \overline{B}^0 mixing parameter $X=0.143\pm0.023$. 178 ADRIANI 92D use both electron and muon semileptonic decays. For this measurement ADRIANI 92D average over all \sqrt{s} values to obtain a single result. 179 ADRIANI 92D use both electron and muon semileptonic decays. The quoted systematic error is common to all measurements. The peak value is superseded by ACCIARRI 94D.

CHARGE ASYMMETRY IN $e^+e^- \rightarrow q \overline{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on $\mathcal{B}^0 \cdot \overline{\mathcal{B}}^0$ mixing and on other electroweak parameters.

Gauge & Higgs Boson Particle Listings Z, Higgs Bosons — H^0 and H^{\pm}

Higgs Bosons — H^0 and H^{\pm} , Searches for

THE HIGGS BOSON

(by I. Hinchliffe, LBNL)

The Standard Model [1] contains one neutral scalar Higgs boson, which is a remnant of the mechanism that breaks the $\mathrm{SU}(2) \times \mathrm{U}(1)$ symmetry and generates the W and Z boson masses. The Higgs couples to quarks and leptons of mass m_f with a strength $gm_f/2M_W$. Its coupling to W and Z bosons is of strength g, where g is the coupling constant of the $\mathrm{SU}(2)$ gauge theory. Consequently its coupling to stable matter is very small, and its production and detection in experiments is difficult. An exception is its production in the decay of the Z boson. Since large numbers of Z's can be produced and the coupling of the Z to the Higgs is unsuppressed, experiments at LEP are now able to rule out a significant range of Higgs masses. The branching ratio of the Higgs boson into various final states is shown in Fig. 1.

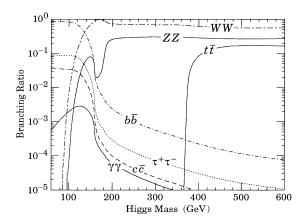

Figure 1: The branching ratio of the Higgs boson into $\gamma\gamma$, $\tau\bar{\tau}$, $b\bar{b}$, $t\bar{t}$, $c\bar{c}$, ZZ, and WW as a function of the Higgs mass. In the latter cases, if $M_H < 2M_Z$ (or $M_H < 2M_W$), the value indicated is the rate to ZZ^* (or WW^*) where Z^* (W^*) denotes a virtual Z (W). The $c\bar{c}$ rate depends sensitively on the poorly-determined charmed quark mass.

If the Higgs mass is very large, the couplings of the Higgs to itself and to longitudinally polarized gauge bosons become large. Requiring that these couplings remain weak enough so that perturbation theory is applicable implies that $M_H \lesssim 1$ TeV [2]. While this is not an absolute bound, it is an indication of the mass scale at which one can no longer speak of an elementary Higgs boson. This fact is made more clear if one notes that the width of the Higgs boson is proportional to the cube of its mass (for $M_H > 2M_Z$) and that a boson of mass 1 TeV has a width of 500 GeV.

It is believed that scalar field theories of the type used to describe Higgs self-interactions can only be effective theories valid over a limited range of energies if the Higgs self-coupling and hence Higgs mass is nonzero. A theory of this type that is valid at all energy scales must have zero coupling. The range of energies over which the interacting theory is valid is a function of the Higgs self-coupling and hence its mass. An upper bound on the Higgs mass can then be determined by requiring that the theory be valid (i.e., have a nonzero value of the renormalized Higgs self-coupling) at all scales up to the Higgs mass [3]. Nonperturbative calculations using lattice [4] gauge theory that can be used to compute at arbitrary values of the Higgs mass indicate that $M_H \lesssim 770~{\rm GeV}$.

If the Higgs mass were small, then the vacuum (ground) state with the correct value of M_W would cease to be the true ground state of the theory [5]. A theoretical constraint can then be obtained from the requirement that this is not the case, i.e., that our universe is in the true minimum of the Higgs potential. The constraint depends upon the top quark mass and upon the scale (Λ) up to which the Standard Model remains valid. This scale must be at least 1 TeV, resulting in the constraint [7] $M_H > 72 \text{ GeV} + 0.9 (m_{\text{top}} - 174 \text{ GeV})$. The bound increases monotonically with the scale, for $\Lambda = 10^{19} \text{ GeV}$, $M_H > 135 \text{ GeV} + 2.1 \text{ (}m_{\text{top}} - 174 \text{ GeV)}.$ This constraint may be too restrictive. Strictly speaking we can only require that the predicted lifetime of our universe, if it is not at the true minimum of the Higgs potential, be longer than its observed age [8,9]. For $\Lambda=1$ TeV there is no constraint; and for $\Lambda = 10^{19} \text{ GeV } M_H > 120 \text{ GeV} + 2.3 (m_{\text{top}} - 174 \text{ GeV}) [10].$

Experiments at LEP are able to exclude a large range of Higgs masses. They search for the decay $Z \to HZ^*$. Here Z^* refers to a virtual Z boson that can appear in the detector as e^+e^- , $\mu^+\mu^-$, $\tau^+\tau^-$, $\nu\overline{\nu}$ (i.e., missing energy) or hadrons. The experimental searches have considered both $H\to$ hadrons and $H\to \tau^+\tau^-$. The best limits are shown in the Particle Listings below.

Precision measurement of electroweak parameters such as M_W and the various asymmetries at LEP and SLC are becoming sensitive enough that they can in principle constrain the Higgs mass through its effect in radiative corrections. Currently, the precision tests allow the entire range from the direct LEP limit ($M_H \gtrsim 60$ GeV) to 1 TeV [11] at 95% confidence level although fits prefer the lower end of this range. The recent determination of the top mass has improved the constraint on M_H . See the article in this volume on the "Standard Model of Electroweak Interactions."

The search range for Higgs bosons will expand shortly when LEP begins operation at higher energy. The process $e^+e^- \to ZH$ [12] should enable neutral Higgs bosons of masses up to ~ 0.97 ($\sqrt{s}-M_Z$) to be discovered [13]. If the Higgs is heavier than this, its discovery will probably have to wait until experiments at the LHC have data. If the neutral Higgs boson has mass greater than $2M_Z$, it will likely be discovered via its decay to ZZ and the subsequent decay of the Z's to charged

Gauge & Higgs Boson Particle Listings Higgs Bosons — H^0 and H^{\pm}

leptons (electrons or muons) or of one Z to charged leptons and the other to neutrinos. A challenging region is that between the ultimate limit of LEP and $2M_Z$. At the upper end of this range the decay to a real and a virtual Z, followed by the decay to charged leptons is available. The decay rate of the Higgs boson into this channel falls rapidly as M_H is reduced and becomes too small for $M_H \lesssim 140$ GeV. For masses below this, the decays $H \to \gamma \gamma$ and possibly $H \to b\bar{b}$ [14] are expected to be used. The former has a small branching ratio and large background, the latter has a large branching ratio, larger background and a final state that is difficult to fully reconstruct [15].

Extensions of the Standard Model, such as those based on supersymmetry [16], can have more complicated spectra of Higgs bosons. The simplest extension has two Higgs doublets whose neutral components have vacuum expectation values v_1 and v_2 , both of which contribute to the W and Z masses. The physical particle spectrum contains one charged Higgs boson (H^{\pm}) , two neutral scalars (H_1, H_2) ,* and one pseudoscalar (A). In the simplest version of the supersymmetric model, the mass the lightest of these scalars depends upon the top quark mass, the ratio v_2/v_1 , and the masses of the other supersymmetric particles. For $m_t = 174$ GeV, there is a bound $M_{H_1} \lesssim 125$ GeV [18,19]. In models where all fermions of the same electric charge receive their masses from only one of the two doublets $(v_2 \text{ gives mass to the charge } 2/3 \text{ quarks, while } v_1 \text{ gives mass}$ to the charged leptons and the charge 1/3 quarks), there are, as in the Standard Model, no flavor-changing neutral currents at lowest order in perturbation theory. The H_1 , H_2^0 , and Acouplings to fermions depend on v_2/v_1 and are either enhanced or suppressed relative to the couplings in the Standard Model. Experiments at LEP are able to exclude ranges of masses for neutral Higgs particles in these models. These ranges depend on the values of v_2/v_1 . See the Particle Listings below on H_1^0 , Mass Limits in Supersymmetric Models.

Charged Higgs bosons can be pair produced in e^+e^- annihilation. Searches for charged Higgs bosons depend on the assumed branching fractions to $\nu\tau$, $c\overline{s}$, and $c\overline{b}$. Data from LEP now exclude charged Higgs bosons of mass less than 43.5 GeV [20]. See the Particle Listings for details of the H^\pm Mass Limit.

A charged Higgs boson could be produced in the decay of a top quark, $t \to H^+b$. Searches for this decay at hadron colliders should be possible [21].

HO (Higgs Boson) MASS LIMITS

These limits apply to the Higgs boson of the three-generation Standard Model with the minimal Higgs sector. Limits that depend on the $Ht\bar{t}$ coupling may also apply to a Higgs boson of an extended Higgs sector whose couplings to up-type quarks are comparable to or larger than those of the standard one-doublet model H^0 couplings.

For comprehensive reviews, see Gunion, Haber, Kane, and Dawson, "The Higgs Hunter's Guide," (Addison-Wesley, Menlo Park, CA, 1990) and R.N. Cahn, Reports on Progress in Physics 52 389 (1989). For a review of theoretical bounds on the Higgs mass, see M. Sher, Physics Reports (Physics Letters C) 179 273 (1989).

- 1 ABREU 94G searched for $Z\to~H^0+(e^+e^-,\,\mu^+\mu^-,\,\tau^+\tau^-,\,\nu\overline{\nu})$ with $H^0\to~q\,\overline{q}$. Four $\ell^+\ell^-$ candidates were found (all yielding low mass) consistent with expected back-
- AKERS 94B searched for $Z \to H^0 + (e^+e^-, \mu^+\mu^-, \nu\overline{\nu})$ with $H^0 \to q\overline{q}$. One $\nu\overline{\nu}$ and one $\mu^+\mu^-$ candidate were found consistent with expected backgrounds. ³ ADRIANI 93C searched for $Z \to H^0 + (\nu \overline{\nu}, e^+e^-, \mu^+\mu^-)$ with H^0 decaying hadroni-
- cally or to $au \overline{ au}$. Two e^+e^- and one $\mu^+\mu^-$ candidates are found consistent with expected
- ⁴ BUSKULIC 93H searched for $Z \rightarrow H^0 \nu \overline{\nu}$ (acoplanar jets) and $Z \rightarrow H^0 + (e^+ e^-)$ $\mu^+\mu^-$) (lepton pairs in hadronic events).
- ⁵ GROSS 93 combine data taken by four LEP experiments through 1991.
- ⁶ ABREU 92D give $\sigma(e^+e^-\to Z\to H^0\gamma)$ ·B($H^0\to {\rm hadrons})$ <8 pb (95% CL) for m_{H^0} <75 GeV and E_γ >8 GeV.
- 7 ABREU 92J searched for $Z o H^0 + (ee, \mu\mu, au au,
 u\overline{
 u})$ with $H^0 o q\overline{q}$. Only one candidate was found, in the channel ee + 2jets, with a dijet mass 35.4 \pm 5 GeV/ c^2 , consistent with the expected background of 1.0 \pm 0.2 events in the 3 channels $e^+\,e^ \mu^+\mu^-$, $\tau^+\tau^-$, and of 2.8 \pm 1.3 events in all 4 channels. This paper excludes 12–38 GeV. The range 0–12 GeV is eliminated by combining with the analyses of ABREU 90C
- GeV. The range 0–12 GeV is eminimated 3, 2.... and ABREU 91B. 8 ADEVA 92B searched for $Z \to H^0 + (\nu \overline{\nu}, ee, \mu \mu, \tau \tau)$ with $H^0 \to$ anything, $Z \to H^0 + \tau \tau$ with $H^0 \to q \overline{q}$, and $Z \to H^0 + q \overline{q}$ with $H^0 \to \tau \tau$. The analysis excludes the range $30 < m_{H^0} < 52$ GeV.
- ⁹ ADRIANI 92F give $\sigma(e^+e^- \rightarrow Z \rightarrow H^0\gamma)$ ·B($H^0 \rightarrow$ hadrons) <(2–10) pb (95% CL) for $m_{\chi^0} = 25$ –85 GeV. Using $\sigma(e^+e^- \rightarrow Z) = 30$ nb, we obtain B($Z \rightarrow H^0\gamma$)B($H^0 \rightarrow H^0\gamma$)B(H^0 hadrons) $<(0.7-3) \times 10^{-4}$ (95% CL).
- 10 DECAMP 92 searched for most possible final states for $Z\to H^0\,Z^*.$ 11 ABREU 91B searched for $Z\to H^0+\ell\bar\ell$ with missing H^0 and $Z\to H^0+(\nu\bar\nu,\ell\bar\ell,$ $q\overline{q}$) with $H^0 \rightarrow ee$.
- ¹² ACTON 91 searched for $e^+e^- \rightarrow Z^*H^0$ where $Z^* \rightarrow e^+e^-$, $\mu^+\mu^-$, or $\nu\overline{\nu}$ and $H^0 \rightarrow e^+e^$ anything. Without assuming the minimal Standard Model mass-lifetime relationship, the limit is $m_{H^0} > 9.5~{\rm GeV}$.
- $H^0 + (\mu \mu, ee, \nu \overline{\nu})$. This paper only excludes 15 < 13 ADEVA 91 searched for Z $m_{H^0} \, < \,$ 41.8 GeV. The 0–15 GeV range is excluded by combining with the analyses of previous L3 papers.
- ¹⁴ ADEVA 91D obtain a limit B($Z \rightarrow H^0 \gamma$)·B($H^0 \rightarrow \text{hadrons}$) < 4.7 × 10⁻⁴ (95%CL) for $m_{H^0}=$ 30–86 GeV. The limit is not sensitive enough to exclude a standard H^0
- ¹⁵ AKRAWY 91 searched for the channels $Z \to H^0 + (\nu \overline{\nu}, ee, \mu \mu, \tau \tau)$ with $H^0 \to$ $q\overline{q}$, $\tau\tau$, and $Z \rightarrow H^0 q\overline{q}$ with $H^0 \rightarrow \tau\tau$.
- ¹⁶ AKRAWY 91C searched the decay channels $Z \to H^0 + (\nu \overline{\nu}, ee, \mu \mu)$ with $H^0 \to q \overline{q}$.

- 17 ABE 90E looked for associated production of H^0 with W^\pm or Z in $p\overline{p}$ collisions at \sqrt{s} = 1.8 TeV. Searched for H^0 decays into $\mu^+\mu^-$, $\pi^+\pi^-$, and K^+K^- . Most of the excluded region is also excluded at 95% CL.
- ¹⁸ ABREU 90c searched for the channels $Z \rightarrow H^0 + (\nu \overline{\nu}, ee, \mu \mu)$ and $H^0 + q \overline{q}$ for m_H < 1 GeV.
- ¹¹⁹ ADEVA 90H searched for $Z \rightarrow H^0 + (\mu \mu, ee, \nu \overline{\nu})$.
- ²⁰ ADEVA 90N looked for $Z \to H^0 + (ee, \mu\mu)$ with missing H^0 and with $H^0 \to ee$, $\mu\mu$, $\pi^{+}\pi^{-}$, $K^{+}K^{-}$.
- 21 AKRAWY 90C based on 825 nb $^{-1}$. The decay $Z \to H^0 \nu \overline{\nu}$ with $H^0 \to \tau \overline{\tau}$ or $q \overline{q}$ provides the most powerful search means, but the quoted results sum all channels.
- ²² AKRAWY 90P looked for $Z \to H^0 + (ee, \mu\mu)$ (H^0 missing) and $Z \to H^0 \nu \overline{\nu}$, $H^0 \to H^0 \nu \overline{\nu}$
- 23 DECAMP 90 limits based on 11,550 Z events. They searched for $Z \rightarrow H^0 + (\nu \overline{\nu}, ee,$ $\mu\mu$, $\tau\tau$, $q\overline{q}$). The decay $Z\to H^0 \nu\overline{\nu}$ provides the most powerful search means, but the quoted results sum all channels. Different analysis methods are used for $m_{H^0} < 2m_{\mu}$ where Higgs would be long-lived. The 99% confidence limits exclude $m_{H^0} = 0.040$ –12

- GeV. GeV. 24 DECAMP 90H limits based on 25,000 $Z \to {\rm hadron~events}$. 25 DECAMP 90M looked for $Z \to H^0 \, \ell \ell$, where H^0 decays outside the detector. 26 DECAMP 90N searched for the channels $Z \to H^0 + (\nu \overline{\nu}, \ ee, \ \mu \mu, \ \tau \tau)$ with $H^0 \to {\rm hadron}$

- 27 CHANKOWSKI 95 fit to LEP, SLD, and W mass data available in the spring of 1995 plus $m_{t}=176\pm13$ GeV. Exclusion of the SLD data increases the mass to $m_{H}=121-\frac{207}{58}$ GeV (m_{H} <800 GeV at 95% CL).
- ²⁸ ERLER 95 fit to LEP, SLC, W mass, and various low-energy data available in the summer of 1994 plus m_t =174 ± 16 GeV from CDF. The limit without m_t is 880 GeV. However, the preference for lighter m_H is due to R_b and A_{LR} , both of which do not agree well with the Standard Model prediction.
- ²⁹ MATSUMOTO 95 fit to LEP, SLD, W mass, and various neutral current data available in the summer of 1994 plus $m_{\rm H}{=}180\pm13$ GeV from CDF/DØ, and the LEP direct limit $m_{\rm H}{>}63$ GeV. $\alpha_S(m_Z)=0.124$ is used. Fixing $\alpha_S(m_Z)=0.116$ lowers the upper limit to 440 GeV. Dependence on $\alpha(m_Z)$ is given in the paper.
- 30 ELLIS 94 fit to LEP, SLD, *W*-mass, and neutrino data available in the summer of 1993. The fit to m_H , m_t , and α_s yields m_t = 140 $^{+21}_{-22}$ GeV and $\alpha_s(m_Z)$ = 0.116 $^{+0.007}_{-0.006}$.
- 31 ELLIS 94B fit to LEP, SLD, W mass, neutral current data available in the spring of 1994 plus $m_{\tilde{t}}=167\pm12$ GeV determined from CDF/D0 $t\bar{t}$ direct searches. $\alpha_{\rm S}(m_Z)=0.118\pm0.007$ is used. The fit yields $m_{\tilde{t}}=162\pm9$ GeV. A fit without the SLD data gives $m_H = 130 + 320_{-90}$ GeV.
- 32 GURTU 94 fit to LEP, SLD, W mass, neutral current data available in the spring of 1994 as well as $m_t=174\pm16$ GeV. A fit without $\Gamma(Z\to b\overline{b})/\Gamma(Z\to hadrons)$ gives $m_H = 120 + 364_{-60}^{+364} \text{ GeV}.$
- 33 MONTAGNA 94 fit to LEP and SLD, W-mass data together with $m_{ au}$
- -- MOVI LAGNA 94 TIT to LEP and SLD, W-mass data together with $m_t=174\pm17$ GeV. Although the data favor smaller Higgs masses, the authors do not regard it significant. 34 BLONDEL 93 perform two dimensional (m_t-m_H) fit to LEP electroweak data available in the spring of 1993. $\alpha_S=0.117\pm0.005$ is used and $m_t>108$ GeV, $m_H>62.5$ GeV imposed. $m_{H^0}=1$ TeV is compatible with the data within two standard deviations.
- 35 ELLIS 93B fit to LEP and neutrino data available in the summer of 1993. m_t is adjusted to minimize χ^2 and $\alpha_S(m_Z)=0.123\pm0.006$ is used. 95% CL limit for m_H <250 GeV
- 36 NOVIKOV 93B use a subset of the most accurate and "gluon-free" data available in the spring of 1993. They use m_W , $\Gamma(\ell\ell)$, and $A_{FB}^{\ell\ell}$.
- 37 DELAGUILA 928 perform two dimensional (m_t-m_H) fit to various LEP, neutrino, eH, and $p\bar{p}$ data available through 1991 with direct limits on $m_t,~m_H.~$ The result m_H =65 $^+$ 24 $^+$ 24 is not expected from the statistical sensitivity of the data but due to deviation of the data from the Standard Model expectation.
- 38 ELLIS 92 result is from a fit to electroweak data from LEP and elsewhere. They also find $m_H <$ 160 GeV at 68%CL and 0.5 $< m_H <$ 1500 GeV at 90%CL with m_t unconstrained.
- 39 ELLIS 92E perform fit to electroweak data available in the spring of 1992. m_{t} is adjusted to minimize χ^2 and $\alpha_s(m_Z) = 0.118 \pm 0.008$ is used.

Higgs Bosons — H^0 and H^{\pm}

- $^{
 m 40}$ RENTON 92 use electroweak data available in 1991 and require m_{H} >50 GeV. The constraint α_s = 0.114 \pm 0.007 was used.
- 41 SCHAILE 92 performs fit to LEP electroweak data (as of summer 1991) as well as m_W (UA2/CDF) and ν N (CDHS/CHARM). The fit with the constraint m_H >50 GeV gives m_H =50 $^{+192}_{-0}$ GeV. However, the m_H dependence of the χ^2 is not consistent from that expected from the present statistics and the sensitivity to m_H arises from the fact that the measured values of g_A and A_{BB}^F deviate from the Standard Model expectation. Therefore, the result is not considered to be significant.

- 42 CASAS 95 require stability of the vacuum in the <code>minimal</code> Standard Model up to the scale Λ and find $m_H>127.9+1.92 (m_t-174)-4.25 (\alpha_s(m_Z)-0.124)/0.0006$ (units in GeV) for $\Lambda=10^{19}$ GeV, and $m_H>$ 52 GeV for $\Lambda=1$ TeV, $m_t=174$ GeV, $\alpha_s(m_Z)$
- 43 ESPINOSA 95B require metastability of the vacuum in the <code>minimal</code> Standard Model up to the scale Λ and find $m_H>[2.278\ -\ 4.654(\alpha_s(m_Z)\ -\ 0.124)]m_t$ $-\ 277$ GeV for Λ
- 44 ALTARELLI 94 require the stability of the vacuum in the *minimal* Standard Model and find $m_H >$ 72 (135) GeV for the cut-off scale $\Lambda=1$ TeV (10¹⁹ GeV), if $m_t=1$ 74 GeV and $\alpha_S(m_Z)=0.118$. See paper for $m_t,\,\alpha_S$, and Λ dependence of the result.
- and $\alpha_{\rm S}(m_Z)=0.118$. See paper for m_t , $\alpha_{\rm S}$, and γ dependence of the result. 45 BARABASH 92 is a beam dump experiment that searched for $H^0 \to e^+e^-$ and $\gamma \gamma$ produced via the decays $\pi \to e \nu_e H^0$, $K \to e \nu_e H^0$, $K \to \pi H^0$, and $\eta' \to \eta H^0$. The last process gives the best limit if the theoretical calculation by RUSKOV 87 is used. 46 EGL1 89 give a limit for $B(\pi^+ \to e^+ \nu H^0) \cdot B(H^0 \to e^+ e^-)$ ranging from 10^{-9} to
- 10^{-11} for the mass range 10–110 MeV. The theoretical prediction they use is too large by a factor of 162/49 (see DAWSON 89, DAWSON 90, and CHENG 89). The lower limit given above is reevaluated by us.
- limit given above is reevaluated by us.

 47 LINDNER 89 require vacuum stability and numerically solve the renormalization equations to two-loop order. If m_{top} = 100, 110, 120 GeV, then m_{Higgs} > 20, 34, 50 GeV. However, it is possible that the vacuum is not stable but is very long-lived.

 48 YEPES 89 reanalyzed a BNL beam-dump experiment (JACQUES 80) which looked for the dump and found none.
- for $m_{H^0}=0.25$ –0.409 GeV. However, the number 0.409 is not well-determined due to theoretical uncertainties in B($H^0 \rightarrow \mu^+\mu^-$)
- 50 Limits from cosmological considerations of \$SU(2) \times U(1) symmetry-breaking phase transition occurring only after extreme supercooling, resulting in too high a ratio of entropy to baryon number. Limits apply to the standard one-doublet model H^0 , with 'zero bare mass' whose physical mass is determined by the Coleman-Weinberg mechanism of dynamical symmetry breakdown. These limits depend on the mass of the top quark approximately according to $m_{H^0} > 10.4[1-4m_t^4/(2m_W^4+m_Z^4)]^{1/2}$ GeV when $m_t < 80$ GeV. So for $m_t \approx 80$ GeV, there is no limit. If $m_t > 80$ GeV, then vacuum stability arguments may give bounds on m_H , see LINDNER 89 above.

H⁰ (Higgs Boson) MASS LIMITS in Extended Higgs Models

The parameter x denotes the Higgs coupling to charge -1/3 quarks and charged leptons relative to the value in the standard one-Higgs-doublet model.

In order to prevent flavor-changing neutral currents in models with more than one Higgs doublet, only one of the Higgs doublets can couple to quarks of charge 2/3. The same requirement applies independently to charge -1/3 quarks and to leptons. Higgs couplings can be enhanced or suppressed.

- $^{51}\mathrm{See}$ Fig. 4 of ABREU 95H for the excluded region in the $m_{\ensuremath{H^0}}-m_{\ensuremath{A^0}}$ plane for general two-doublet models. For aneta > 1, the region $m_{H^0} + m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL
- 52 BRAHMACHARI 93 consider Higgs limit from Z decay when the Higgs decays to invisible modes. If H^0 coupling to Z is at least $1/\sqrt{2}$ of the Standard Model H^0 , the DECAMP 92 limit of 48 GeV changes within ± 6 GeV for arbitrary B($H^0 \rightarrow SM$ -like)+B($H^0 \rightarrow SM$ -like)
- 53 See Fig. 1 of BUSKULIC 93I for the limit on ZZH^0 coupling for a general Higgs having a similar decay signature to Standard Model Higgs boson or decaying invisibly. If the decay rate for $Z o H^0 Z^*$ is >10% of the minimal Standard Model rate, then $m_{H^0} >$ 40
- GeV. For the standard rate the limit is 58 GeV. 54 BUSKULIC 931 limit for H^0 with the standard coupling to Z but decaying to weakly interacting particles.
- 55 LOPEZ-FERNANDEZ 93 consider Higgs limit from Z decay when the Higgs decays to invisible modes. See Fig. 2 for excluded region in m_{H^0} -ZZH coupling plane with arbitrary B($H^0 \rightarrow SM$ -like)+B($H^0 \rightarrow invisible$)=1. $m_H > 50$ GeV is obtained if the H^0 coupling strength to the Z is greater than 0.2 times the Standard Model rate.
- 56 See Fig. 1 of ADRIANI 92G for the limit on ZZH^0 coupling for a general Higgs having a similar decay signature to Standard Model Higgs boson. For most masses below 30 GeV, the rate for $Z \rightarrow H_1^0 Z^*$ is less than 10% of the Standard Model rate.
- 57 PICH 92 analyse ${\it H^0}$ with m_{H^0} <2 m_{\mu} in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and π^\pm , η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.
- 58 ACTON 91 limit is valid for any H^0 having $\Gamma(Z \to H^0 Z^*)$ more than 0.24 (0.56) times that for the standard Higgs boson for Higgs masses below $2m_\mu~(2m_\tau)$.
- 59 DECAMP 91F search for $Z \to H^0 \, \ell^+ \ell^-$ where H^0 escapes before decaying. Combining this with DECAMP 90M and DECAMP 90N, they obtain $B(Z \to H^0 \ell^+ \ell^-)/B(Z)$ $\ell^{+}\ell^{-}) < 2.5 \times 10^{-3} \text{ (95\%CL) for } m_{H^0} < 60 \text{ GeV}.$
- 60 See Figs. 1, 3, 4, 5 of DECAMP 911 for excluded regions for the masses and mixing angles in general two-doublet models.
- 61 AKRAWY 90P limit is valid for any H^0 having $\Gamma(Z\to H^0\,Z^*)$ more than 0.57 times that for the Standard Higgs boson.
- 62 DAVIER 89 give excluded region in m_{H^0} -x plane for m_{H^0} ranging from 1.2 MeV to 50
- 63 SNYDER 89 give limits on B(B \rightarrow H⁰X)·B(H⁰ \rightarrow e⁺e⁻) for 100 < m_{H⁰} < 200
- 64 First order QCD correction included with $\alpha_s \approx 0.2$. Their figure 4 shows the limits vs.
- 65 ALBRECHT 85J found no mono-energetic photons in both $\varUpsilon(1S)$ and $\varUpsilon(2S)$ radiative decays in the range 0.5 GeV < E(γ)<4.0 GeV with typically BR< 0.01 for $\varUpsilon(1S)$ and BR< 0.02 for $\varUpsilon(2S)$ at 90% CL. These upper limits are 5–10 times the prediction of the standard Higgs-doublet model. The quoted 90% limit B($\varUpsilon(1S) \rightarrow H^0 \gamma) < 1.5 \times 10^{-3}$ at $E(\gamma)=1.07$ GeV contradicts previous Crystal Ball observation of $(4.7\pm1.1)\times10^{-3}$; see their reference 3. Their figure 8a shows the upper limits of x^2 as a function of $E(\gamma)$ by assuming no QCD corrections. We used $m_{H^0}=m\,\gamma\,\,(1-2{\it E}(\gamma)/m\,\gamma)^{1/2}.$

H₁⁰ (Higgs Boson) MASS LIMITS in Supersymmetric Models

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars $[H_1^0 \text{ and } H_2^0]$, where we define $m_{H_1^0} < m_{H_2^0}]$,

a pseudoscalar (A^0), and a charged Higgs pair (H^\pm). H^0_1 and H^0_2 are also called h and H in the literature. There are two free parameters in the theory which can be chosen to be m_{A^0} and $\tan\beta=\nu_2/\nu_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H^0_1} \leq$

 $m_Z, m_{H^0} \geq m_Z, m_{A^0} \geq m_{H^0}$, and $m_{H^\pm} \geq m_W$. However, as described in the "Note on Supersymmetry," recent calculations of one-loop radiative corrections show that these relations may be violated. Many experimental analyses have not taken into account these corrections; footnotes indicate when these corrections are included. The results assume no invisible H^0 or A^0 decays.

- ⁶⁶ ABREU 95H search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. Two-loop corrections are included with m_t =170 GeV, $m_{\widetilde{t}}$ =1 TeV. Including only one-loop corrections does not change the
- 67 AKERS 94I search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. One-loop corrections are included with $m_t <$ 200 GeV, $m_{\widetilde{t}} <$ 1 TeV. See Fig. 10 for limits for $\tan \beta <$ 1.
- ⁶⁸ BUSKULIC 931 search for $Z \rightarrow H_1^0 Z^*$ and $Z \rightarrow H_1^0 A^0$. One-loop corrections are included with any m_t , $m_{\widetilde{t}} > m_t$.
- ⁶⁹ ADRIANI 92G search for $Z \to H_1^0 Z^*$, $Z \to H_1^0 A^0 \to 4b$, $bb\tau\tau$, 4τ , 6b (via $H^0 \to H_1^0 A^0 \to H_1^0 A^0 \to H_1^0 A^0 \to H_1^0 A^0$ A^0 A^0), and include constraints from $\Gamma(Z)$. One-loop corrections to the Higgs potential are included with $90 < m_t < 250$ GeV, $m_t < m_{\widetilde t} < 1$ TeV.
- ⁷⁰ ROSIEK 95 study the dependence of $m_{H_1^0}$ limit on various supersymmetry parameters.
- They argue that H_1^0 as light as 25 GeV is not excluded by ADRIANI 92G data in the region $m_{A^0}\sim$ 60 GeV If $m_{\widetilde{t}}\lesssim$ 200 GeV and $\widetilde{t}_L.\widetilde{t}_R$ mixing is large. ⁷¹ ABREU 940 study $H_1^0A^0\to$ four jets and combine with ABREU 94G analysis. The
- limit applies if the H_1^0 A mass difference is <4 GeV.
- 72 ABREU 92J searched for $Z\to H_1^0Z^*$ and $Z\to H_1^0A^0$ with H_1^0 , $A^0\to \tau\tau$ or jet-jet. Small mass values are excluded by ABREU 91B.
- 73 ABREU 91B result is based on negative search for $Z \rightarrow H_1^0 f \overline{f}$ and the limit on invisible Z width $\Gamma(Z \rightarrow H_1^0 A^0) < 39$ MeV (95%CL), assuming $m_{A^0} < m_{H_1^0}$
- 74 ABREU 91B result obtained by combining with analysis of ABREU 901. 75 AKRAWY 91C result from $Z\to H_1^0A^0\to 4{\rm jet}$ or $\tau^+\tau^-{\rm j}j$ or 4τ and $Z\to H_1^0Z^*$ ($H_1^0\to q\bar q,Z^*\to \nu\bar\nu$ or e^+e^- or $\mu^+\mu^-$). See paper for the excluded region for the case $\tan \beta < 1$. Although these limits do not take into account the one-loop radiative corrections, the authors have reported unpublished results including these corrections and showed that the excluded region becomes larger.
- 76 BLUEMLEIN 91 excluded certain range of $\tan\beta$ for $m_{H_1^0} <$ 120 MeV, $m_{A^0} <$ 80 MeV.
- ⁷⁷ DECAMP 911 searched for $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0 \to 4$ jets or $\tau \tau jj$ or $3A^0$. Their limits take into account the one-loop radiative corrections to the Higgs potential with varied too and count more search. with varied top and squark masses.
- 78 ABREU 90E searched for $Z \rightarrow H_1^0 A^0$ and $Z \rightarrow H_1^0 Z^*$. $m_{H_1^0} < 210$ MeV is not excluded by this analysis.
- 79 ADEVA 90R result is from $Z \to H_1^0 A^0 \to 4$ jet or $\tau \tau jj$ or 4τ and $Z \to H_1^0 Z^*$. Some region of $m_{H_1^0} < 4$ GeV is not excluded by this analysis.
- ⁸⁰ DECAMP 90E look for $Z \to H_1^0 A^0$ as well as $Z \to H_1^0 \ell^+ \ell^-$, $Z \to H_1^0 \nu \overline{\nu}$ with 18610 Z decays. Their search includes signatures in which H_1^0 and A^0 decay to $\gamma \gamma$, $e^+ e^-$, $\mu^+\mu^-$, $\tau^+\tau^-$, or $q\,\overline{q}$. See their figures of $m_{H_1^0}$ vs. $\tan\beta$.
- 81 DECAMP 90H is similar to DECAMP 90E but with 25,000 Z decays.
- 82 DECAMP 90M looked for $Z \to H^0 \ell \ell$, where H^0_1 decays outside the detector. This excludes a region in the $(m_{H_1^0}, \tan\beta)$ plane centered at $m_{H_1^0} = 50$ MeV, $\tan\beta = 0.5$. This limit together with DECAMP 90E result excludes $m_{H_1^0} < 3$ GeV for any $\tan\beta$.

A⁰ (Pseudoscalar Higgs Boson) MASS LIMITS in Supersymmetric Models

Limits on the ${\it A}^{0}$ mass from $e^{+}\,e^{-}$ collisions arise from direct searches in the $e^{+}\,e^{-}$ $A^0\,H^0_1$ channel and indirectly from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H^0_+}$. As discussed in the "Note on Supersymmetry," at the one-loop level and in the simplest cases, these relations depend on the masses of the t quark and \tilde{t} squarks. The limits are weaker for larger t and \tilde{t} masses, while they increase with the inclusion of two-loop radiative corrections. Some specific examples of these dependences are provided in the footnotes to the listed papers.

- 83 ABREU 95H search for $Z\to H_1^0Z^*$ and $Z\to H_1^0A^0$. One-loop corrections are included with $m_t=170$ GeV, $m_{\widetilde{t}}=1$ TeV. The limit becomes weak for larger m_t : at $m_t=190$ GeV, the limit is 14 GeV. The limit at $m_t=170$ GeV would increase to 39 GeV if two-loop radiative corrections were included. m_t and $m_{\widetilde{t}}$ dependences are shown in ...
- rig. o. 84 AKERS 94I search for $Z \to H_0^0 Z^*$ and $Z \to H_0^0 A^0$. One-loop corrections are included with $m_t <$ 200 GeV, $m_{\widetilde{t}} <$ 1 TeV. See Fig. 10 for limits for $\tan \beta <$ 1.
- 85 BUSKULIC 93I search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. One-loop corrections to the Higgs potential are included with any m_t , $m_{\widetilde{t}} > m_t$. For $m_t =$ 140 GeV and $m_{\widetilde{t}} = 1$ TeV, the limit is $m_{A^0} > 45$ GeV. Assumes no invisible H^0 or A^0 decays.
- ⁸⁶ ADRIANI 92G search for $Z \rightarrow H_1^0 Z^*$, $Z \rightarrow H_1^0 A^0 \rightarrow 4b$, $bb\tau\tau$, 4τ , 6b (via $H^0 \to A^0 A^0$), and include constraints from $\Gamma(Z)$. One-loop corrections are included with $90 < m_t < 250$ GeV, $m_t < m_{\widetilde t} < 1$ TeV. The region $m_{A^0} < 11$ GeV is allowed if $42 < m_{H^0} < 62$ GeV, but is excluded by other experiments.
- ⁸⁷ABREU 940 study H_1^0 $A^0 o ext{ four jets and combine with ABREU 94G analysis. The}$ limit applies if the $H_1^{0-}A^0$ mass difference is <4 GeV.
- ⁸⁸ ELLIS 93 analyze possible constraints on the MSSM Higgs sector by electroweak precision measurements and find that m_{A0} is not constrained by the electroweak data.
- ⁸⁹ ABREU 92J searched for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$ with $H_1^0 \cdot A^0 \to \tau \tau$ or jet-jet. Small mass values are excluded by ABREU 91B.
- ⁹⁰ BUSKULIC 92 limit is from $\Gamma(Z)$, $Z \rightarrow H_1^0 Z^*$, and $Z \rightarrow H_1^0 A^0$. The limit is valid for any $m_{H_1^0}$ below the the theoretical limit $m_{H_1^0}$ <64 GeV which holds for $m_{A^0} \sim 0$ in the minimal supersymmetric model. One-loop radiative corrections are included.
- the minimal supersymmetric model. One-loop radiative corrections are included. 91 AKRAWY 91C result from $Z \to H_1^0 A^0 \to 4$ jet or $\tau^+ \tau^- jj$ or 4τ . See paper for the excluded region for the case $\tan \beta < 1$. 92 DECAMP 91I searched for $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0 \to 4$ jets or $\tau \tau jj$ or $3A^0$. Their limits take into account the one-loop radiative corrections to the Higgs potential with varied top and squark masses. For $m_t = 140$ GeV and $m_{\widetilde{q}} = 1$ TeV, the limit is $m_{A^0} > 31 \text{ GeV}.$
- ⁹³ ABREU 90E searched $Z \to H_1^0 A^0$ and $Z \to H_1^0 Z^*$. $m_{A^0} <$ 210 MeV is not excluded
- by this alrayshs. q^2A DEVA 90R result is from $Z\to H_1^0A^0\to 4$ jet or $\tau\tau jj$ or 4τ and $Z\to H_1^0Z^*$. Some region of $m_{A^0}<5$ GeV is not excluded by this analysis.

MASS LIMITS for Associated Higgs Production in e^+e^- Interactions

In multi-Higgs models, associated production of Higgs via virtual or real Z in e^+e^- annihilation, $e^+e^- \to H_1^0 H_2^0$, is possible if H_1^0 and H_2^0 have opposite CP eigenvalues. Limits are for the mass of the heavier Higgs H_2^0 in two-doublet models.

- 95 AKERS 94I search for $Z\to H_1^0\,H_2^0$ with various decay modes. See Fig.11 for the full excluded mass region in the general two-doublet model, from which the limit above is taken. In particular, for $m_{H_1^0}=m_{H_2^0}$ the limit becomes $>\!38$ GeV.
- 96 ADRIANI 92G excluded regions of the $m_{H_1^0}-m_{A^0}$ plane for various decay modes with
- limits B($Z \to H_1^0 H_2^0$) <(2–20) × 10⁻⁴ are shown in Figs. 2–5. 97 DECAMP 90H search for $Z \to H_1^0 e^+ e^-$, $H_1^0 \mu^+ \mu^-$, $H_1^0 \tau^+ \tau^-$, $H_1 q \overline{q}$, low multiplicity final states, τ - τ -jet-jet final states and 4-jet final states.
- 98 KOMAMIYA 90 limits valid for $\cos^2(\alpha-\beta)\approx 1$. They also search for the cases $H_1^0 \to 0$
- $\mu^+\mu^-$, $\tau^+\tau^-$, and $H_2^0\to H_1^0H_1^0$. See their Fig. 2 for limits for these cases. 99 KOMAMIYA 89 assume B($H_1^0\to\mu^+\mu^-$) = 100 %, $2m_\mu < m_{H_1^0} < m_\tau$. The limit is for maximal mixing. A limit of $m_{H_2^0} >$ 18 GeV for the case $H_2^0 \rightarrow H_1^0 H_1^0$ ($H_1^0 \rightarrow$ $\mu^+\,\mu^-)$ is also given. From PEP at $\tilde{E_{\rm CM}}=$ 29 GeV.
- $^{100}\mathrm{LOW}$ 89 assume that H_1^0 escapes the detector. The limit is for maximal mixing. A reduced limit of 24 GeV is obtained for the case $H_2^0 \to H_1^0 f \overline{f}$. Limits for a Higgs-triplet model are also discussed. $E_{
 m cm}^{\it ee}=$ 50–60.8 GeV.
- $^{101}\,\mathrm{The}$ limit assumes maximal mixing and that H_1^0 escapes the detector.
- $^{102}\mathrm{ASH}$ 85 assumes that H_1^0 escapes undetected. The bound applies up to a mixing suppression factor of 5.

H± (Charged Higgs or Techni-pion) MASS LIMITS

Most of the following limits assume B($H^+ \rightarrow \tau^+ \nu$) + B($H^+ \rightarrow c\overline{s}$) = 1. DE-CAMP 90i, BEHREND 87, and BARTEL 86 assume B($H^+
ightarrow au^+
u$) + B($H^+
ightarrow$ $c\overline{s}) + B(H^+ \rightarrow c\overline{b}) = 1$. All limits from Z decays as well as ADACHI 90B assume that H^+ has weak isospin $T_3=\pm1/2$. For a discussion of techni-particles, see EICHTEN 86.

- 103 ABREU 940 study $H^+H^-\to c\overline{s}\,s\overline{c}$ (four-jet final states) and $H^+H^-\to \tau\nu_{\tau}\,\tau\nu_{\tau}.$ Limit for B($\tau\nu_{\tau})=$ 1 is 45.4 GeV.
- $^{104}\,\mathrm{ADRIANI}$ 92G limit improves to 44 GeV if $\mathrm{B}(\tau\nu_{\tau})>$ 0.4.
- ¹⁰⁵ Studied $H^+H^- \rightarrow (\tau \nu) + (\tau \nu)$, $H^+H^- \rightarrow (\tau \nu) + \text{hadrons}$, $H^+H^- \rightarrow \text{hadrons}$.
- 106 DECAMP 92 limit improves to 45.3 GeV for B($\tau \nu$)=1. 107 BUSKULIC 95 give a limit $\tan \beta/m_{H^+} < 0.52 \text{ GeV}^{-1}$ (90%CL) for Type-II models from $b \rightarrow \tau \nu_{\tau} X$ branching ratio.
- 108 ABE 94H search for $t\overline{t}$ production in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV, followed by the decay chain $t \to bH^+$, $H^+ \to \tau^+\nu_\tau$, τ decaying hadronically. The search is sensitive to the region $m_{H^+} < m_t - m_b < m_W$. See their Fig. 3 for the excluded region for $\tan \beta \ge 0.5$ and their Fig. 4 for that in the two-Higgs-doublet model. 109 ABE 94I search for $t\bar{t}$ production in $\rho\bar{p}$ collisions at $E_{\rm Cm} = 1.8$ TeV, followed by the
- decay chain $t\to bH^+$, $H^+\to \tau^+\nu_T$, τ decaying leptonically. For B($H^+\to \tau\nu_T$)=1 (0.5), the region $m_{H^+}< m_t-m_b$, $m_t<(95-110)$ GeV (70 GeV) is excluded at 95% CL. See Fig. 3 for the excluded parameter region in the two-Higgs-doublet model.

- 110 HEWETT 93 and BARGER 93 analyze charged Higgs contribution to $b
 ightarrow s \gamma$ in twodoublet models with the CLEO limit B($b \to s\gamma$) 8.4 × 10 –4 (99% CL) and find be limits on m_{H^\pm} in the type of model (model II) in which different Higgs are responsible for up-type and down-type quark masses. HEWETT 93 give m_{H^+} >110 (70) GeV for m_t >150 (120) GeV using m_b = 5 GeV. BARGER 93 give m_{H^+} >155 GeV for m_t = 150 GeV using m_b = 4.25 GeV. The authors employ leading logarithmic QCD corrections and emphasize that the limits are quite sensitve to m_b .
- 111 BELANGER 93 make an analysis similar to BARGER 93 and HEWETT 93 with an improved CLEO limit B($b \rightarrow s \gamma$) < 5.4 × 10⁻⁴ (95%CL). For the Type II model, the limit m_{H^+} >540 (300) GeV for m_t >150 (120) GeV is obtained. The authors employ leading logarithmic QCD corrections.
- 112 ALITTI 92F search for $t \to bH^+$, $H^+ \to \tau \nu_{\tau}$ with τ decaying hadronically in $p\overline{p}$ collisions at $E_{\rm cm}=630$ GeV. m_{H^+} between 40 and 65 GeV is excluded if m_t-m_H = m_b + (\lesssim a few-10 GeV). See Figs. 5, 6 for the excluded region for B(H^+ \to $\tau \nu_{\tau}$) = 1, 0.5.
- = 1, 0.5. 113 ALBAJAR 91B search for $W\to t\,\overline{b}$ and $t\,\overline{t}$ production in $p\,\overline{p}$ collisions with the decay chain $t\to H^+\,b$, $H^+\to \tau^+\nu$, in single muon plus jets and dimuon channels. For $m_t=60$ GeV, $m_{H^+}<47$ GeV is excluded at 95%CL if $\tan\beta>2.3$. The search is restricted to small values of m_t , and no limit on m_{H^+} is obtained if $m_t>61$ GeV. Note that existing limits on m_t are not valid if $t \to H^+ b$.
- 114 YUZUKI 91 assume photon exchange. The limit is valid for any decay mode $H^+ \to e \nu$, $\mu \nu$, $\tau \nu$, $q \overline{q}$ with five flavors. For B($\ell \nu$) = 1, the limit improves to 25.0 GeV.
- 115 ABREU 90B limit improves to 36 GeV for B(au
 u) = 1.
- $^{116}_{-}$ ADACHI 90B limit improves to 22 GeV for B($\tau\nu)=$ 0.6.
- 117 ADEVA 90M limit improves to 42.5 GeV for B(au
 u)=1.
- $^{118} \, {\rm AKRAWY}$ 90K limit improves to 43 GeV for ${\rm B}(\tau \, \nu) = 1.$
- 119 If B($H^+ \rightarrow \tau^+ \nu$) = 100%, the DECAMP 901 limit improves to 43 GeV.
- 120 SMITH 90B limit applies for $v_2/v_1\ > 2$ in a model in which H_2 couples to u-type quarks and charged leptons.
- 121 Studied $H^+H^ \rightarrow$ $(\tau \nu)$ + $(\tau \nu)$, $H^+H^- \rightarrow (\tau \nu)$ + hadrons. Search for muon opposite hadronic shower.

MASS LIMITS for H^{±±} (doubly-charged Higgs boson)

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT

Heavy Bosons Other Than Higgs Bosons, Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B and COLANGELO 91. $g_R=g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 898. Limits on the $W_L\text{-}W_R$ mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- ¹ JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^{\pm}
- spectrum in the decay of the highly polarized μ^+ . ² KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_{\nu} \cdot \sigma_{\eta} \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.
- of polarized neutrons. Zero mixing assumed. See also NUZNETSOV 949.

 3 KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_{\nu} \cdot \sigma_{n} \rangle$ in the β decay of polarized neutrons. Zero mixing assumed.

 4 BHATTACHARYYA 93 uses $Z \cdot Z'$ mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t =200 GeV and slightly improves for smaller m_t .
- 5 SEVERIJNS 93 measured polarization-asymmetry correlation in $^{107} \ln \beta^+$ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum. 6 IMAZATO 92 measure positron asymmetry in $K^+ \to -\mu^+ \nu_\mu$ decay and obtain
- $\xi P_{\mu}>$ 0.990 (90%CL). If W_R couples to $u\overline{s}$ with full weak strength $(V_{u\overline{s}}^R=1)$, the result corresponds to $m_{W_R}>$ 653 GeV. See their Fig. 4 for m_{W_R} limits for general $|V_{us}^R|^2 = 1 - |V_{ud}^R|^2$.
- ⁷ POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta=0$. Supersedes POLAK 91.
- 8 AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.
- ⁹COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.
- 10 POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta=0$. Superseded by POLAK 92B.
- 11 BARBIERI 898 limit holds for $m_{\nu_R} \leq$ 10 MeV.
- 12 LANGACKER 898 limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.
- class or right-handed quark mixing matrices.

 13 BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.
 14 STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
- $^{15}\,\mathrm{BERGSMA}$ 83 set limit $m_{\,W_{\!2}}/m_{\,W_{\!1}}~>$ 1.9 at CL = 90%.
- 16 CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from V-A at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{WR} >\!\!\! >\!\! 240$ GeV. Assumes a light right-handed neutrino.
- 17 BEALL 82 limit is obtained assuming that W_R contribution to κ_Q^0 + κ_S^0 mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L - W_R Mixing Angle ζ

CL%

VALUE

Lighter mass eigenstate $W_1=W_L\cos\zeta-W_R\sin\zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

- 18 MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{\nu}_{\mu} N \to \overline{\nu}_{\mu} X$ events at Tevatron, assuming left-handed ν and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m_{W_1}^2/m_{W_2}^2)<$ 0.0015. The limit is independent of ν_R mass.
- ¹⁹AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed 20 BARBIERI 898 limit holds for $m_{\nu_R} \leq 10$ MeV.
- $^{21}\,\mathrm{First}$ JODIDIO 86 result assumes $\stackrel{\sim}{m}_{W_{R}}=\infty$, second is for unconstrained $m_{W_{R}}$

Gauge & Higgs Boson Particle Listings Heavy Bosons Other than Higgs Bosons

MASS LIMITS for W' (A Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\overline{p}\to W'X$ with W' decaying to the mode indicated in the comments. New decay channels (e.g., $W'\to WZ$ are assumed to be suppressed. Experiments other than ABE 95M, ABACHI 95E, and ABE 91F assume that the $t\overline{b}$ channel is not open.

- 22 ABE 95M assume that the decay $W'\to WZ$ is suppressed and the (right-handed) neutrino is light, noninteracting, and stable. If $m_{\nu}{=}60$ GeV, for example, the effect on the mass limit is neglibible.
- ²³ ABACHI 95E assume that the decay $W' \rightarrow WZ$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.
- $^{24}\text{ALITTI 93}$ search for resonances in the two-jet invariant mass. The limit assumes $\Gamma(W')/m_{W'}=\Gamma(W)/m_W$ and $\text{B}(W'\to jj)=2/3$. This corresponds to W_{R} with $m_{\nu_R} > m_{W_R}$ (no leptonic decay) and $W_R \to t\, \overline{b}$ allowed. See their Fig. 4 for limits in the $m_{W'} - B(q\overline{q})$ plane.
- 25 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.
- 26 ABE 91F assume leptonic branching ratio of 1/12 for each lepton flavor. The limit from GeV and ν_R does not decay in the detector. Cross section limit $\sigma \cdot {\rm B} < (1-10)\,{\rm pb}$ is given for $m_{W'}=100$ –550 GeV; see Fig. 2.
- ²⁷ ALITTI 91 search is based on two-jet invariant mass spectrum, assuming B($W' o q \overline{q}$)
- = 67.6%. Limit on σ · B as a function of two-jet mass is given in Fig. 7. ²⁸ ALBAJAR 89 cross section limit at 630 GeV is $\sigma(W')$ B($e\nu$) < 4.1 pb (90% CL).
- ²⁹ See Fig. 5 of ANSARI 87D for the excluded region in the $m_{W'}$ -[$(g_{W'}q)^2$ B(W' \rightarrow $(e\overline{
 u})$ plane. Note that the quantity $(g_{W'q})^2$ B($W'
 ightharpoonup (e\overline{
 u})$ is normalized to unity for the standard W couplings.
- the standard W couplings. 30 ARNISON 868 find no excess at large p_T in 148 $W \rightarrow e \nu$ events. Set limit $\sigma \times B(e \nu) < 10$ pb at CL = 90% at $E_{\rm cm} = 546$ and 630 GeV. 31 ARNISON 83D find among 47 $W \rightarrow e \nu$ candidates no event with excess p_T . Also set $\sigma \times B(e \nu) < 30$ pb with CL = 90% at $E_{\rm cm} = 540$ GeV.

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z) THE Z' SEARCHES

The mass bounds depend on the gauge group and the gauge coupling of a Z' boson. The limits listed below are not exhaustive but include only typical Z' bosons that appear frequently in the literature. The following notations are used for these Z' bosons.

 Z'_{SM} : Z'_{SM} is a clone of the Z and is introduced as a convenient way to gauge the limits rather than with a theoretical motivation. It is assumed to have exactly the same couplings as the Z but a different mass.

Left-right symmetric bosons: Z_{LR} is the extra neutral boson which appears in left-right symmetric models with the gauge group $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ or $SU(2)_L \times U(1)_R \times$ $U(1)_{B-L}$, where $U(1)_R$ is the third component of $SU(2)_R$ and the weak hypercharge $Y = T_{3R} + \frac{1}{2}(B-L)$. The Z_{LR} couples to $\alpha T_{3R} - (1/2\alpha)(B-L)$ with the coupling strength g' (the weak hypercharge gauge coupling). The parameter α is model dependent. For left-right symmetric coupling $g_L = g_R$, $\alpha = (1 - 2\sin^2\theta_W)^{1/2}/\sin\theta_W \approx 1.53$, which is used for the limits in the listing unless noted. Another typical case $\alpha = (2/3)^{1/2}$ is identical to Z_{χ} (discussed below) with the coupling $g_{\chi} = g'$.

E₆ bosons: Two new neutral gauge bosons appear in E₆ models. One is contained in the SO(10) subgroup and the other is not:

$$\mathrm{E}_{6} \longrightarrow \mathrm{SO}(10) \times \mathrm{U}(1)_{\psi}$$
 ,

$$SO(10) \longrightarrow SU(5) \times U(1)\chi$$
.

One Z' is assumed to be relatively light, which in general is a linear combination of the two:

$$Z_{\beta} = Z_{\chi} \cos \beta + Z_{\psi} \sin \beta .$$

The gauge quantum numbers of the ordinary quarks and leptons are shown in the table:

f	T_{3R}	Y	$B{-}L$	$\sqrt{24}Q\chi$	$\sqrt{\frac{72}{5}}Q_{\psi}$	Q_{η}
$\phantom{aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa$	0	$-\frac{1}{2}$	-1	+3	+1	$+\frac{1}{6}$
$ u_R$	$+\frac{1}{2}$	0	-1	+5	-1	$+\frac{5}{6}$
e_R^-	$-\frac{1}{2}$	-1	-1	+1	-1	$+\frac{1}{3}$
u_L, d_L	0	$+\frac{1}{6}$	$+\frac{1}{3}$	-1	+1	$-\frac{1}{3}$
u_R	$+\frac{1}{2}$	$+\frac{2}{3}$	$+\frac{1}{3}$	+1	-1	$+\frac{1}{3}$
d_R	$-\frac{1}{2}$	$-\frac{1}{3}$	$+\frac{1}{3}$	-3	-1	$-\frac{1}{6}$

In particular, the χ charge is related to others by $\sqrt{24}Q_{\chi} =$ 4Y - 5(B-L). Also notice that the Z_{ψ} coupling is pure axial for all quarks and leptons.

Another typical case Z_{η} is defined as

$$Z_{\eta} = \sqrt{\frac{3}{8}} Z_{\chi} - \sqrt{\frac{5}{8}} Z_{\psi} ,$$

which appears in a superstring-motivated model.

A reference gauge coupling for these bosons is g' = $e/\cos\theta_W$, which is predicted if there is no intermediate symmetry breaking scale.

In general, these Z' models require the existence of a set of new fermions (belonging to the 27 representation of E₆) to cancel gauge anomalies, and possibly superpartners. An exception is Z_{χ} , for which only right-handed neutrinos are necessary. For the direct limits from hadron colliders, it is often assumed that these new fermions are heavy and are not produced in the decay of the Z'.

- $^{32}\,\mathrm{ABE}$ 95 limit is obtained assuming that Z' decays to known fermions only.
- 33 LANGACKER 928 fit to a wide range of electroweak data including LEP results available early '91. m_t >89 GeV used.
- 34 LANGACKER 92B give 95%CL limits on the Z-Z' mixing -0.0086 < heta < 0.0005. $^{35}\,\mathrm{VILAIN}$ 94B assume $m_{\,t}=$ 150 GeV.
- ³⁶ ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes B($Z' \to q \overline{q}$)=0.7. See their Fig. 5 for limits in the $m_{Z'}$ -B($q \overline{q}$) plane.
- ³⁷ ALLEN 93 limit is from total cross section for $\nu e \to \nu e$, where $\nu = \nu_e$, ν_μ , $\overline{\nu}_\mu$.
- 38 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to
- the inclusion of the assumed K factor. 39 ABE 91D give $\sigma(Z') \cdot B(e^+e^-) < 1.31$ pb (95%CL) for $m_{Z'} > 200$ GeV at $E_{\rm cm} = 1.8$ TeV. Limits ranging from 2 to 30 pb are given for $m_{Z'} = 100$ –200 GeV.
- ⁴⁰ GEIREGAT 91 limit is from comparison of g_V^e from $\nu_\mu e$ scattering with $\Gamma(Z \to ee)$ from LEP. Zero mixing assumed.
- 41 ABE 90° use data for R, R_{ℓ} , and A_{ℓ} . They fix $m_W=80.49\pm0.43\pm0.24$ GeV and $m_Z=91.13\pm0.03$ GeV.
- 42 HAGIWARA 90 perform a fit to $e^+\,e^-$ data at PEP, PETRA, and TRISTAN including
- $\mu^+\,\mu^-$, $\tau^+\,\tau^-$, and hadron cross sections and asymmetries. ⁴³ ALBAJAR 89 cross section limit at 630 GeV is $\sigma(Z')$ B(ee) < 4.2 pb (90% CL).
- ⁴⁴ See Fig. 5 of ANSARI 87D for the excluded region in the $m_{Z'}$ -[$(g_{Z'q})^2$ B(Z' \to $e^+e^-)]$ plane. Note that the quantity $(g_{Z'q})^2$ B $(Z' o e^+e^-)$ is normalized to unity for the standard Z couplings.
- 45 ARNISON 86B find no excess e^+e^- pairs among 13 pairs from Z. Set limit $\sigma \times B(e^+e^-)$ <13 pb at CL = 90% at $E_{\rm cm}$ = 546 and 630 GeV.

Limits for Z_{LR}

 \mathcal{L}_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- $^{
 m 46}\,{
 m ABE}$ 95 limit is obtained assuming that Z' decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric
- $^{\rm 47}$ LANGACKER 928 fit to a wide range of electroweak data including LEP results available early '91. m_t >89 GeV used.
- ⁴⁸LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0025 < \theta < 0.0083$.
- 49 VILAIN 94B assume $m_{ extit{t}}=$ 150 GeV and heta=0. See Fig.2 for limit contours in the mass-mixing plane.
- mass-mixing plane. 50 ADRIANI 93D give limits on the Z-Z' mixing $-0.002 < \theta < 0.015$ assuming the ABE 928 mass limit. 51 ALTARELLI 93B limit is from LEP data available in summer '93 and is for $m_t = 110$ GeV. $m_H = 100$ GeV and $\alpha_S = 0.118$ assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z-Z' mixing angle is in Table 4.
- their Fig. 5). The 90% of limit on the Z-Z mixing angle is in Jaure 4.

 52 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

 53 These limits assume that Z' decays to known fermions only.

 54 These limits assume that Z' decays to all E₆ fermions and their superpartners.

- 55 See Fig. 7b and 8 in DELAGUILA 92 for the allowed region in $m_{Z^{\prime}}$ -mixing plane and $m_{Z'} - m_t$ plane from electroweak fit including '90 LEP data.
- 56 LAYSSAC 92B limit is from LEP data available spring '92. Specific Higgs sector is
- assumed. See also LAYSSAC 92. 57 POLAK 92 limit is from m_{W_R} >477 GeV, which is derived from muon decay parameters assuming light ν_R . Specific Higgs sector is assumed.
- assuming light ν_R . Specific rings sector is assumed. S8 POLAK 928 limit is from a simultaneous fit to charged and neutral sector in SU(2)_L×SU(2)_R×U(1) model using Z parameters, m_W , and low-energy neutral current data as of 1991. Light ν_R assumed and $m_t = m_H = 100$ GeV used. Supersedes POLAK 91. S9 RENTON 92 limits use LEP data taken up to '90 as well as m_W , ν N, and atomic parity with the data. Specific Higgs structure is assumed.
- NEUTON 22 mints use Let data taken up to 30 as well as m_W , DN, and atomic party violation data. Specific Higgs structure is assumed. 60 ALTARELLI 91B is based on Z mass, widths, and A_{FB} . The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and $m_{H0} < 1$ TeV assumed. For large m_t , the bound improves drastically. Bounds for Z- Z^\prime mixing angle and Z mass shift without this model assumption are also given in the
- From ν N neutral current data with $m_Z=91.10\pm0.04$ GeV, $m_t>77$ GeV, $m_{H^0}<1$ TeV assumed.
- TeV assumed. GeV polark 91 limit is from a simultaneous fit to charged and neutral sector in $\mathrm{SU}(2)_L \times \mathrm{SU}(2)_R \times \mathrm{U}(1)$ model using $m_W, \, m_Z,$ and low-energy neutral current data as of 1990. Light ν_R assumed and $m_t = m_H = 100$ GeV used. Superseded by POLAK 928. Garrier Special Speci
- 64 HE 90B model assumes a specific Higgs sector. Neutral current data of COSTA 88 as well as m_Z is used. g_R is left free in the fit.
- $^{65}\,\mathrm{BARBIERI}$ 898 limit holds for $m_{\nu_R} \leq$ 10 MeV.
- ⁶⁶ DELAGUILA 89 limit is based on $\sigma(p\overline{p}\to Z')\cdot B(Z'\to e^+e^-)<1.8$ pb at CERN $p\overline{p}$
- collider.

 67 A wide range of neutral current data as of 1986 are used in the fit.
- $^{68}\,\mathrm{A}$ wide range of neutral current data as of 1985 are used in the fit.
- 69 ADEVA 85B measure asymmetry of μ -pair production, following formalism of RIZZO 81.

Limits for Z_{χ} Z_{χ} is the extra neutral boson in SO(10) \to SU(5) \times U(1) χ . $g_{\chi}=e/\cos\theta_{W}$ is assumed unless otherwise stated. We list limits with the assumption $\rho=1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed

- $^{70}\,\mathrm{ABE}$ 95 limit is obtained assuming that Z' decays to known fermions only. See their Fig. 3 for the mass bound of Z^\prime decaying to all allowed fermions and supersymmetric
- 71 LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t >$ 89 GeV used.
- 72 LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0048 < \theta < 0.0097$.
- T-LANGALKER 92B give 95%-CL limits on the Z-2' mixing −0.0048 < θ < 0.0097.
 3ABREU 95M limit is for α_S=0.123, m_F=150 GeV, and m_H=300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13.
 NARDI 95 give 90%CL limits on Z-Z' mixing −0.0032 < θ < 0.0031 for M_Z, >500 GeV, m_F=170 GeV, α_S=0.12. The bound is relaxed under the simultaneous presence of the mixing of the known fermions with new heavy states, −0.0032 < θ < 0.0070.
- 75 BUSKULIC 94 give 95%CL limits on the Z-Z' mixing -0.0091 < heta < 0.0023
- 76 VILAIN 94B assume $m_{ extit{t}}=$ 150 GeV and heta=0. See Fig. 2 for limit contours in the
- 77 ADRIANI 93D give limits on the Z- Z^{\prime} mixing $-0.004 < \theta < 0.015$ assuming the ABE 92B mass limit.
- 78 ALTARELI 938 limit is from LEP data available in summer '93 and is for $m_t=110$ GeV. $m_H=100$ GeV and $\alpha_S=0.118$ assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z-Z' mixing angle is in their Fig. 2.
- 79 These limits assume that Z' decays to known fermions only. 80 These limits assume that Z' decays to all E $_6$ fermions and their superpartners.
- 81 See Fig. 7a and 8 in DELAGUILA 92 for the allowed region in $m_{Z^{\prime}}$ -mixing plane and $m_{Z^{\prime}}-m_t$ plane from electroweak fit including '90 LEP data.
- 82 LAYSSAC 92B limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92.
 83 LEIKE 92 is based on '90 LEP data published in LEP 92.
- 84 RENTON 92 limits use LEP data taken up to '90 as well as m_W , ν N, and atomic parity violation data. Specific Higgs structure is assumed.
- ⁸⁵ ALTARELLI 91B is based on Z mass, widths, and A_{FB} . The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and $m_{H^0} < 1$ TeV assumed. For large m_t , the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the
- 86 BUCHMUELLER 91 limit is from LEP data. Specific assumption is made for the Higgs
- sector. 87 DELAGUILA 91 bounds have extra assumption of superstring motivated Higgs sector. From ν N neutral current data with $m_Z=91.10\pm0.04$ GeV, $m_{t}>77$ GeV, $m_{H^0}<1$
- 88 FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_{
 u}~<~0.5$ and is valid for $m_{
 u_R}^{}~<~1$ MeV.
- 89 GONZALEZ-GARCIA 91 limit is based on low-energy neutral current data, Z mass and widths, m_W from ABE 90G, 100 $<\!m_t<\!$ 200 GeV, $m_{H^0}=\!$ 100 GeV assumed. Dependence on m_t is shown in Fig. 7.
- 90 MAHANTHAPPA 91 limit is from atomic parity violation in Cs with $m_W,\,m_Z.$
- $^{91}\,\mathrm{ABE}$ 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}.$
- 92 ABE 90F fix $m_{W}=80.49\pm0.43\pm0.24$ GeV and $m_{Z}=91.13\pm0.03$ GeV.
- $^{93}e^+e^-$ data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{c\overline{c}}$ below Z as well as $\nu_{\mu}e$ scattering data of GEIREGAT 89 is used in the fit. 94 BARGER 90B limit is based on CDF limit $\sigma(p\overline{p}\to Z')\cdot B(Z'\to e^+e^-)<1$ pb
- (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z' decay.
- 95 GLASHOW 90 model assumes a specific Higgs sector. See GLASHOW 90B.
- ⁹⁶ These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_{
 u} < 1$) constrains Z' masses if $u_{\mathcal{R}}$ is light ($\lesssim 1$ MeV).
- 97 GRIFOLS 90 limit holds for $m_{\nu_R}\lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.
- 98 HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-,~\tau^+\tau^-,$ and hadron cross sections and asymmetries. The upper mass limit disappears at 2.7 s.d.
- ⁹⁹ DELAGUILA 89 limit is based on $\sigma(p\bar{p}\to Z')$ B($Z'\to e^+e^-$) < 1.8 pb at CERN $p\bar{p}$
- 100 DORENBOSCH 89 obtain the limit $(g_\chi/g_Z)^2 \cdot (m_Z/m_{Z_\chi})^2 < 0.11$ at 95% CL from the processes $\overline{\nu}_{\mu}\,e\,\rightarrow\,\,\overline{\nu}_{\mu}\,e$ and $\nu_{\mu}\,e\,\rightarrow\,\,\overline{\nu_{\mu}}\,e$.
- $^{101}\,\mathrm{A}$ wide range of neutral current data as of 1986 are used in the fit.
- $^{102}\,Z^\prime$ mass limits from non-observation of an excess of $\ell^+\,\ell^-$ pairs at the CERN $p\,\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z^\prime decays only into light quarks and leptons.
- 103 MARCIANO 87 limit from unitarity of Cabibbo-Kobayashi-Maskawa matrix.
- $104\,\mathrm{A}$ wide range of neutral current data as of 1985 are used in the fit.

Limits for Z_{ψ} Z_{ψ} is the extra neutral boson in E₆ \rightarrow SO(10) \times U(1) $_{\psi}$. $g_{\psi}=e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho=1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- $^{105} \mathrm{ABE}$ 95 limit is obtained assuming that Z' decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric fermions.
- 106 LANGACKER 928 fit to a wide range of electroweak data including LEP results available early '91. m_t >89 GeV used.
- 107 LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0025~<~\theta<~0.013$.
- 108 ABREU 95M limit is for α_{S} =0.123, m_{t} =150 GeV, and m_{H} =300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13.
- NARDI 95 give 90%CL limits on Z-Z' mixing $-0.0056 < \theta < 0.0055$ for $M_{Z'} >$ 500 GeV, m_t =170 GeV, m_H =250 GeV, α_S =0.12. The bound is relaxed under the simultaneous presence of the mixing of the known fermions with new heavy states, $-0.0066 < \theta <$
- 111 ADRIAN 930 give limits on the Z-Z' mixing $-0.003 < \theta < 0.020$ assuming the ABE 92B mass limit. 112 These limits assume that Z' decays to known fermions only.
- 113 These limits assume that Z^\prime decays to all E $_6$ fermions and their superpartners.
- 114 LEIKE 92 is based on '90 LEP data published in LEP 92.
- $^{115}\,\mathrm{ABE}$ 90F use data for R, $R_{\ell\,\ell}$, and $A_{\ell\,\ell}$
- $^{116} \mathrm{ABE}$ 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
- The Her Barrian W = 0.0.3 ± 0.0.3 ± 0.0.4 Gebox Z as well as $\nu_{\mu}e$ scattering data of GEIREGAT 89 is used in the fit.

 118 BARGER 908 limit is based on CDF limit $\sigma(p\bar{p}\to Z')\cdot B(Z'\to e^+e^-)<1$ pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z' decay.
- 119 These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_{
 u} < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).
- 120 GRIFOLS 90D limit holds for $m_{\nu_R}\lesssim 1$ MeV. See also RIZZO 91. $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries. 122A wide range of neutral current data as of 1986 are used in the fit.
- $^{123}\,\mathrm{A}$ wide range of neutral current data as of 1985 are used in the fit.

Limits for Z_n

 Z_{η} is the extra neutral boson in E $_{6}$ models, corresponding to $Q_{\eta}=\sqrt{3/8}~Q_{\chi}~ \sqrt{5/8}~Q_{\psi}\cdot~g_{\eta}=e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho=1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 124 ABE 95 limit is obtained assuming that Z' decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric
- fermions. 125 LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t > 89$ GeV used.
- early 91. m_t >89 GeV used. 126 LANGACKER 928 give 95%CL limits on the Z-Z' mixing $-0.038 < \theta < 0.002$. 127 ABREU 95M limit is for α_s =0.123, m_t =150 GeV, and m_H =300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13. 128 NARDI 95 give 90%CL limits on Z-Z' mixing $-0.0087 < \theta < 0.0075$ for M_{Z^1} >500 GeV,
- m_t =170 GeV, m_H =250 GeV, α_s =0.12. The bound is relaxed under the simultaneous presence of the mixing of the known fermions with new heavy states, -0.0087 $< \theta <$
- 129 VILAIN 94B assume $m_t=$ 150 GeV and heta=0. See Fig. 2 for limit contours in the mass-mixing plane.
- 130 ADRIANI 930 give limits on the Z-Z' mixing $-0.029 < \theta < 0.010$ assuming the ABE 928 mass limit. 131 ALTARELLI 938 limit is from LEP data available in summer '93 and is for $m_t=110$
- GeV. $m_H=100$ GeV and $\alpha_S=0.118$ assumed. The 90%CL limit on the $\it Z-Z'$ mixing angle is in Fig. 2.
- These limits assume that Z' decays to known fermions only.
- 133 These limits assume that Z' decays to all E_6 fermions and their superpartners.
- 134 See Fig. 7d in DELAGUILA 92 for the allowed region in m_{7l} -mixing plane from elec-

- 134 See Fig. 7d in DELAGUILA 92 for the allowed region in m_{Z/r}-mixing plane from electroweak fit including '90 LEP data.
 135 LAYSSAC 92B limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92.
 136 LEIKE 92 is based on '90 LEP data published in LEP 92.
 137 RENTON 92 limits use LEP data taken up to '90 as well as m_W, νN, and atomic parity violation data. Specific Higgs structure is assumed.
 138 ALTARELLI 91B is based on Z mass, widths, and A_{FB}. The limits are for superstring motivated models with extra assumption on the Higgs sector. m_t > 90 GeV and m_{HO} < 1 TeV assumed. For large m_t, the bound improves drastically. Bounds for 2-z^r/z mixing angle and Z mass shift without this model assumption are also given in the Z-Z' mixing angle and Z mass shift without this model assumption are also given in the
- paper. 139 GONZALEZ-GARCIA 91 limit is based on low-energy neutral current data, LEP Z mass and widths, m_W from ABE 906. 100 $< m_t <$ 200 GeV, $m_{H^0} =$ 100 GeV assumed. Dependence on m_t is shown in Fig. 8.
- 140 ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. 141 ABE 90F fix $m_W=80.49\pm0.43\pm0.24$ GeV and $m_Z=91.13\pm0.03$ GeV.
- 142 $_{e}^{+}e^{-}$ data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{C\overline{c}}$ below Z as well as $\nu_{\mu}e$ scattering data of GEIREGAT 89 is used in the fit. 143 BARGER 908 limit is based on CDF limit $\sigma(\rho\overline{\rho}\to Z')$.B($Z'\to e^+e^-$) < 1 pb
- (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z^\prime decay.
- 144 These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_{\nu} < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV). 145 GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91. 146 HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including
- , and hadron cross sections and asymmetries.
- 147 DELAGUILA 89 limit is based on $\sigma(p\,\overline{p}\to Z')\cdot B(Z'\to e^+e^-)<1.8$ pb at CERN $p\,\overline{p}$
- 148 A wide range of neutral current data as of 1986 are used in the fit.
- $^{149}Z_{\eta}$ mass limits obtained by combining constraints from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\bar{p}$ collider and the global analysis of neutral current data by COSTA 88. Least favorable spectrum of three (E_6 27) generations of particles and their superpartners are assumed.
- $^{150}Z'$ mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z^\prime decays only into light quarks and leptons. ¹⁵¹BARGER 868 limit is based on UA1/UA2 limit on $p\overline{p} \rightarrow Z'$, $Z' \rightarrow e^+e^-$ (Lepton
- Photon Symp., Kyoto, '85). Extra decay channels for Z^\prime are assumed not be open.
- $152\,\mathrm{A}$ wide range of neutral current data as of 1985 are used in the fit.

Limits for other Z' $Z_{\beta} = Z_{\chi} \cos \beta + Z_{\psi} \sin \beta$

- 153 Fig. 7c and 7e in DELAGUILA 92 give limits for $an\!eta\!=-1/\sqrt{15}$ and $\sqrt{15}$ from elec-
- troweak fit including '90 LEP data.

 154 ALTARELLI 91 limit is from atomic parity violation in Cs together with LEP, CDF data. Z-Z' mixing is assumed to be zero to set the limit.
- 155 MAHANTHAPPA 91 limit is from atomic parity violation in Cs with m_W , m_Z . See Table III of MAHANTHAPPA 91 (corrected in erratum) for limits on various Z' models.
- 156 GRIFOLS 90c obtains a limit for Z' mass as a function of mixing angle β (his $\theta=\beta-\pi/2$), which is derived from a LAMPF experiment on $\sigma(\nu_{\varrho}\,e)$ (ALLEN 90). The result is shown in Fig. 1.
- 157 See Table I of DELAGUILA 89 for limits on various Z^\prime models.
- 158 $g_{eta}=e/{{\cos} heta_W}$ and ho=1 assumed.

- $^{159}\,\mathrm{A}$ wide range of neutral current data as of 1986 are used in the fit.
- 160 Z' mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\,\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z^\prime decays only into light quarks and leptons.

MASS LIMITS for Leptoquarks from Pair Production

These limits rely only on the color or electroweak charge of the leptoquark.

 161 ABACHI 95G search for scalar leptoquarks using $\mu\mu+{
m jets}$ and $\mu\nu_{\mu}+{
m jets}$ events in $ho\overline{
ho}$ collisions at $E_{\rm cm}=1.8$ TeV. The limit is for B(μq) = B(νq) = 0.5 and improves to >119 GeV for B(μq) = 1.

162 ABE 95U search for scalar leptoquarks of charge Q=2/3 and -1/3 using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{\text{Cm}}=1.8$ TeV. The limit is for $\mathrm{B}(\mu\,q)=\mathrm{B}(\nu\,q)=0.5$ and improves to > 131 GeV for $\mathrm{B}(\mu\,q)=1$.

163 ABACHI 948 search for eejj and $e\nu jj$ events in $\rho\bar{\rho}$ collisions at $E_{\rm cm}=1.8$ TeV. ABACHI 948 obtain the limit >120 GeV for ${\rm B}(eq)={\rm B}(\nu q)=0.5$ and >133 GeV for ${\rm B}(eq)=1$. A change in the ${\rm D}^0$ luminosity monitor constant reduces the first bound to >116 GeV quoted above (see FERMILAB-TM-1911). This limit does not depend on the

164 ABE 93 search for $\ell\ell j$ events in $\rho \bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit is for $B(eq) = B(\nu q) = 0.5$ and improves to >113 GeV for B(eq) = 1. This limit does not depend on electroweak quantum numbers of the leptoquark.

165 Limit is for charge -1/3 isospin-0 leptoquark with B(ℓq) = 2/3.

- 166 First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.
- 167 Limits are for charge -1/3, isospin-0 scalar leptoquarks decaying to ℓ^-q or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks. 168 ADRIANI 93M limit for charge -1/3, isospin-0 leptoquark decaying to au b.
- 169 ADRIANI 93M limit for charge -1/3, isospin-0 leptoquark decaying to τb.
 169 ABREU 92F limit is for charge -1/3 isosin-0 leptoquark with B(μq)=2/3. If first and second generation leptoquarks are degenerate, the limit is 43.0 GeV, and for a charge 2/3 second generation leptoquark 43.4 GeV. Cross-section limit for pair production of states decaying to ℓq is given in the paper.
 170 ALITTI 92E search for ℓℓjj and ℓνjj events in pp̄ collisions at E_{CM}=630 GeV. The limit is for B(eq) = 1 and is reduced to 67 GeV for B(eq) = B(νq) = 0.5. This limit does not depend on electroweak quantum numbers of the leptoquark.
 171 KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of de+ and uv̄ (su+ and cv̄). See paper for limits for specific branching ratios.
- $d\,e^+$ and $u\overline{\,}$ (s $\,\mu^+$ and $\,c\,\overline{\,}$). See paper for limits for specific branching ratios.
- 172 BARTEL 878 limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint B(X ightarrow $c\overline{\nu}_{\mu}$) + B(X ightarrow
- $173\,\mathrm{BEHREND}$ 86B assumed that a charge 2/3 spinless leptoquark, χ , decays either into $s\mu^+$ or $c\overline{\nu}$: $B(X \to s\mu^+) + B(X \to c\overline{\nu}) = 1$.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q- ℓ -leptoquark coupling g_{LQ} . It is often assumed that

- $^{188}\!$ ABE 95N assume axigluons decaying to quarks in the Standard Model only.
- 189 ABE 93G assume $\Gamma(g_A)=N\alpha_S m_{g_A}/6$ with N=10.
- 190 CUYPERS 91 compare $\alpha_{\rm S}$ measured in \varUpsilon decay and that from R at PEP/PETRA energies.
- 191 ABE 90H assumes $\Gamma(g_A) = N\alpha_5 m_{g_A}/6$ with N = 5 ($\Gamma(g_A) = 0.09 m_{g_A}$). For N = 10, the excluded region is reduced to 120–150 GeV.
- 192 ROBINETT 89 result demands partial-wave unitarity of J=0 t $\overline{t} \to t\overline{t}$ scattering amplitude and derives a limit $m_{g_A}>0.5$ m_t . Assumes $m_t>56$ GeV.
- 193 ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A)<0.4$ m_{g_A} assumed. See also BAGGER 88.
- 194 CUYPERS 88 requires $\Gamma(\Upsilon \to gg_A) < \Gamma(\Upsilon \to ggg)$. A similar result is obtained by
- DONCHESKI 88. requires $\Gamma(T \to g g_A) \setminus \Gamma(T \to g g g) \times S$ minimal result is obtained by DONCHESKI 88 requires $\Gamma(T \to g q \overline{q}) / \Gamma(T \to g g g) \times S$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to $m_{g_A} > 21$ GeV.

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, or a photon pair as shown in the comments. The limits are for the product of branching ratios.

- 196 ACTON 93E give $\sigma(e^+e^-\to X^0\gamma)$ -B(X $^0\to \gamma\gamma)<$ 0.4 pb (95%CL) for $m_{\chi0}=60\pm$ 2.5 GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0)$ -B(X $^0\to \gamma\gamma)^2<$ 20 MeV for $m_{\chi0}=60\pm$ 1 GeV.
- 197 ABREU 920 give σ_Z · B($Z \rightarrow \gamma X^0$) · B($X^0 \rightarrow$ hadrons) <(3–10) pb for $m_{X^0} = 10$ –78 GeV. A very similar limit is obtained for spin-1 X^0 .
- 198 ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z + \mathrm{B}(Z \to \gamma X^0) + \mathrm{B}(X^0 \to \mathrm{hadrons}) < (2-10) \,\mathrm{pb}$ (95%CL) is given for $m_{\chi 0} = 25$ –85 GeV.
- 199 ACTON 91 searches for $Z \to Z^* X^0$, $Z^* \to e^+ e^-$, $\mu^+ \mu^-$, or $\nu \overline{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM Higgs boson.
- 200 ACTON 91B limits are for $m_{\chi^0}=$ 60-85 GeV.
- 201 ADEVA 91D limits are for $m_{\chi^0}=$ 30–89 GeV.
- $^{202}\mathrm{ADEVA}$ 91D limits are for $m_{\ensuremath{\chi^0}} =$ 30–86 GeV.
- 203 AKRAWY 90.1 give $\Gamma(Z\to \gamma X^0)\cdot B(X^0\to hadrons)<1.9$ MeV (95%CL) for $m_{X^0}=32\text{--}80$ GeV. We divide by $\Gamma(Z)=2.5$ GeV to get product of branching ratios. For nonresonant transitions, the limit is $B(Z\to \gamma q\,\overline{q})<8.2$ MeV assuming three-body phase space distribution.

MASS LIMITS for a Heavy Neutral Boson Coupling to e+e-

 204 ODAKA 89 looked for a narrow or wide scalar resonance in $e^+\,e^-\,
ightarrow\,$ hadrons at $E_{
m cm}$

= 55.0–60.8 GeV. $_{205\,\mathrm{DERRICK}}$ 86 found no deviation from the Standard Model Bhabha scattering at E_{Cm} = 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+e^-)$ - m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0 , in which case the limit applies for $\Gamma(X^0 \to e^+e^-) =$

30 MeV. 206 ADEVA 85 first limit is from 2γ , $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. $E_{\rm cm}=40$ –47 GeV. Supersedes ADEVA 84.

²⁰⁷BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \rightarrow e^+e^-$ and $\mu^+\mu^$ at $E_{\rm cm}=34.7$ GeV. See Fig. 5 for excluded region in the $m_{\chi^0}-\Gamma(\chi^0)$ plane.

 208 ADEVA 84 and BEHREND 84c have $E_{
m cm}=$ 39.8–45.5 GeV. MARK-J searched X^0 in $e^+e^- \to {\rm hadrons}, 2\gamma, \mu^+\mu^-, e^+e^- {\rm and}$ CELLO in the same channels plus τ pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_X > E_{\rm Cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-) = 2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84c was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

The limit is for $\Gamma(X^0 \to e^+e^-) \cdot B(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0 .

Axions (A^0) and Other Very Light Bosons, Searches for

AXIONS AND OTHER VERY LIGHT BOSONS

In this section we list limits for very light neutral (pseudo) scalar bosons that couple weakly to stable matter. These have been proposed to solve a variety of mostly theoretical concerns. Typical examples are pseudo-Goldstone bosons like axions (A^0) [1], familons [2], and Majorons [3,4], associated, respectively, with spontaneously broken Peccei-Quinn [5], family, and lepton-number symmetries.

In QCD, SU(3) gauge invariance does not forbid a term $\theta(g_s^2/32\pi^2)F^{\mu\nu a}\widetilde{F}_{\mu\nu}^a$ in Lagrangian. However, CP invariance is broken if $\theta \neq 0$ or π , and the parameter θ has to be small $\lesssim 10^{-9}$ in order not to generate too large electric dilopole moment of neutron. This is called strong CP problem. Peccei-Quinn symmetry gives a natural solution to the strong CP problem. The axion mass and its coupling to stable particles are inversely proportional to the scale of Peccei-Quinn symmetry breaking, f_A . The original axion model [1,5] assumed $f_A \sim v$, where $v = (\sqrt{2}G_F)^{-1/2} = 247$ GeV is the scale of the electroweak

symmetry breaking, and had two Higgs doublets as minimal ingredients. By requiring tree-level flavor conservation, the axion mass and its couplings were completely fixed in terms of one parameter, the ratio of the vacuum expectation values of the two Higgs fields. The result of extensive experimental searches for such an axion have been negative [6].

Observation of a narrow-peak structure in positron spectra from heavy ion collisions [7] suggested a particle of mass 1.8 MeV that decays into e^+e^- . Variants of the original axion model, which keep $f_A \sim v$, but drop the constraints of tree-level flavor conservation, were proposed [8]. Extensive searches for this particle, $A^0(1.8 \text{ MeV})$, ended up with another negative result [9].

Another way to save the Peccei-Quinn idea is to introduce a new scale $f_A \gg v$. Then the A^0 mass becomes smaller and its coupling weaker, thus one can easily avoid all the existing experimental limits; such models are called invisible axion models [10,11]. See the note on Invisible Axions later in this section.

Familons arise when there is a global horizontal symmetry (a symmetry which interchanges different generations) broken spontaneously. They could be either scalars or pseudoscalars. An SU(3) horizontal symmetry among three generations is non-anomalous and hence the familons are exactly massless. In this case, familons are scalars. If one has larger horizontal symmetries with separate groups of left-handed and right-handed fields, one also has pseudo-scalar familons. Some of them have flavor-off-diagonal couplings such as $\partial_{\mu}\phi_{F}\bar{d}\gamma^{\mu}s/F$ or $\partial_{\mu}\phi_{F}\bar{e}\gamma^{\mu}\mu/F$, and the decay constant F can be different for individual operators. The decay constants have lower bounds constrained by flavor-changing processes. For instance, $B(K^+ \to \pi^+\phi_F) < 1.7 \times 10^{-9}$ [12] gives $F_{K\pi} > 1.3 \times 10^{11}$ GeV [2].

If there is a global lepton number symmetry and if it breaks spontaneously, there is a Majoron. The triplet Majoron model [4] has a weak-triplet Higgs boson, and the Majoron couples to Z. The original version is now excluded by the invisible Z decay width. The model would remain viable if there were an additional singlet Higgs boson and if the Majoron were mainly a singlet [13]. In the singlet Majoron model [3], lepton number symmetry is broken by a weak-singlet scalar field, and there are right-handed neutrinos that acquire Majorana masses. The left-handed neutrino masses are generated by a "seesaw" mechanism [14]. The scale of lepton number breaking can be much higher than the electroweak scale in this case. Astrophysical constraints require the decay constant to be $\gtrsim 10^9~{\rm GeV}$ [15].

Other light bosons (scalar, pseudoscalar or vector) are constrained by "fifth force" experiments. For a compilation of constraints, see [16].

³ AMSLER 94B looked for a peak in missing-mass distribution.

The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0) > 10^{-23}\,\mathrm{sec}$.

 5 ATIYA 93 looked for a peak in missing mass distribution. The limit is for massless stable A^0 particles and extends to $m_{A^0}{=}80$ MeV at the same level. See paper for dependence on finite lifetime.

 6 ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable A^0 of m_{A^0} =150–250 MeV, and the limit becomes stronger (10 $^{-8}$) for m_{A^0} =180–240 MeV

MeV. 7 NG 93 studied the production of X^0 via $\gamma\gamma\to\pi^0\to\gamma X^0$ in the early universe at $T\simeq 1$ MeV. The bound on extra neutrinos from nucleosyntheis $\Delta N_{\nu}<0.3$ (WALKER 91) is employed. It applies to $m_{X^0}\ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0 .

⁸ ALLIEGRO 92 limit applies for m_{A0} =150–340 MeV and is the branching ratio times the decay probability. Limit is $< 1.5 \times 10^{-8}$ at 99%CL.

 $m_{\chi_0} = 0.130$ MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires χ_0 to be a vector particle.

ilfetime. Covariance requires X^0 to be a vector particle. 10 MEJJERDREES 92 limit applies for $\tau_{X^0}=10^{-23}$ – 10^{-11} sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained for $m_{X^0}=25$ –120 MeV. Angular momentum conservation requires that X^0 has spin ≥ 1 . 11 ATIYA 908 limit is for $\mathrm{B}(K^+\to\pi^+A^0)$ - $\mathrm{B}(A^0\to\gamma\gamma)$ and applies for $m_{A^0}=50$ MeV,

 11 ATIYA 908 limit is for B($K^+\to\pi^+A^0$)·B($A^0\to\gamma\gamma$) and applies for $m_{A^0}=$ 50 MeV, $\tau_{A^0}<10^{-10}$ s. Limits are also provided for 0 < $m_{A^0}<100$ MeV, $\tau_{A^0}<10^{-8}$ s. 12 KORENCHENKO 87 limit assumes $m_{A^0}=1.7$ MeV, $\tau_{A^0}\lesssim10^{-12}$ s, and B($A^0\to12$ K)

 $e^{+}e^{-})=1$. 13 EICHLER 86 looked for $\pi^{+}\to e^{+}\nu A^{0}$ followed by $A^{0}\to e^{+}e^{-}$. Limits on the branching fraction depend on the mass and and lifetime of A^{0} . The quoted limits are valid when $\tau(A^{0})\gtrsim 3$. $\times 10^{-10}$ s if the decays are kinematically allowed.

¹⁴ YAMAZAKI 84 looked for a discrete line in $K^+ \to \pi^+ X$. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.

 $\begin{array}{l} \text{(3-36) MeV}_{\text{i}} \text{ independent of Microst A Costys position)} \text{ of } m_{A^0} < \text{100 MeV as BR} \\ \text{(4. \times10^{-8}$ for $\tau(A^0 \to n\gamma'\text{s})$ > 1. \times10^{-9}$ s, BR < 1.4 \times10^{-6}$ for $\tau < 1. \times10^{-9}$ s.} \end{array}$

 16 ASANO 81B is KEK experiment. Set B($K^+ \to \pi^+ A^0) < 3.8 \times 10^{-8}$ at CL = 90%. 17 ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 (3 $<\!m$ $<\!40$ MeV) contradicts experimental muon anomalous magnetic moments.

$< 1.2 \times 10^{-4}$	90		³¹ SIVERTZ	82	CUSB	$\Upsilon(3S) \rightarrow A^0 \gamma$

 18 BALEST 95 looked for a monochromatic γ from $\varUpsilon(15)$ decay. The bound is for $m_{A0} < 5.0$ GeV. See Fig. 7 in the paper for bounds for heavier $m_{A^0}.$ They also quote a bound on branching ratios 10^3–10^5 of three-body decay $\gamma X \overset{A}{\overline{X}}$ for $0 < m_{\widetilde{X}} < 3.1$ GeV.

19 The combined limit of ANTREASYAN 90c and EDWARDS 82 excludes standard axion with m_{A^0} < 2 m_e at 90% CL as long as $C_{\varUpsilon}C_{J/\psi}$ > 0.09, where C_V ($V=\varUpsilon$, J/ψ) with $m_{A0} < 2m_e$ at 90% CL as long as ${\rm C} \gamma {\rm C} J/\psi > 0.07$, misses ${\rm C}_V < 1.07$, is the reduction factor for $\Gamma(V \to A^0 \gamma)$ due to QCD and/or relativistic corrections. The same data excludes 0.02 < x < 260 (90% CL) if $C\gamma = C_J/\psi = 0.5$, and further combining with ALBRECHT 86D result excludes $5 \times 10^{-5} < x < 260$. x is the ratio of the vacuum expectation values of the two Higgs fields. These limits use conventional assumption $\Gamma(A^0 \to ee) \propto x^{-2}$. The alternative assumption $\Gamma(A^0 \to ee) \propto x^2$ gives a somewhat different excluded region 0.00075 < x < 44.

 m_{A^0} < 20 MeV.

²¹ The second DRUZHININ 87 limit is valid when au_{A^0}/m_{A^0} < 5 imes 10 $^{-13}$ s/MeV and m_{A^0} < 20 MeV.

²² The third DRUZHININ 87 limit is valid when $au_{A^0}/m_{A^0} > 7 imes 10^{-12}$ s/MeV and $m_{A^0}~<$ 200 MeV.

 $^{23}\tau_{A0}^{AO}<1\times10^{-13}{\rm s}$ and $m_{A0}<1.5$ GeV. Applies for $A^0\to\gamma\gamma$ when $m_{A0}<100$ MeV. $^{24}\tau_{A0}>1\times10^{-7}{\rm s}$.

 25 Independent of τ_{A^0} .

²⁶BOWCOCK 86 looked for A^0 that decays into e^+e^- in the cascade decay \varUpsilon (2S) ightarrow $\Upsilon(1S)\pi^+\pi^-$ followed by $\Upsilon(1S)\to A^0\gamma$. The limit for B($\Upsilon(1S)\to A^0\gamma$)B($A^0\to A^0\gamma$) $e^+\,e^-$) depends on m_{A^0} and au_{A^0} . The quoted limit for m_{A^0} =1.8 MeV is at au_{A^0} \sim 2. \times 10⁻¹²s, where the limit is the worst. The same limit $2.\times$ 10⁻³ applies for all lifetimes for masses $2m_e < m_{A^0} < 2m_{\mu}$ when the results of this experiment are combined with the results of ALAM 83. 27 MAGERAS 86 looked for Υ (15) $\rightarrow \ \gamma A^0 \ (A^0 \rightarrow e^+e^-)$. The quoted branching fraction limit is for $m_{A^0} = 1.7$ MeV, at $\tau(A^0) \sim 4.\times$ 10⁻¹³s where the limit is the worst.

worst. 28 ALAM 83 is at CESR. This limit combined with limit for B $(J/\psi \to A^0 \gamma)$ (EDWARDS 82)

excludes standard axion.

29 NICZYPORUK 83 is DESY-DORIS experiment. This limit together with lower limit 9.2×10^{-4} of B($\Upsilon\to A^0\,\gamma$) derived from B(J/ ψ (1S) $\to A^0\,\gamma$) limit (EDWARDS 82) excludes standard axion.

excludes standard axion. 30 EDWARDS 82 looked for $J/\psi \to \gamma A^0$ decays by looking for events with a single To free graph $\sim 1/2$ the $J/\psi = 7\gamma$ decays by looking in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

 31 SIVERTZ 82 is CESR experiment. Looked for $m au
ightarrow \gamma A^{0}$, A^{0} undetected. Limit for 1S (3S) is valid for m_{A^0} <7 GeV (4 GeV).

		³⁷ AMALDI ³⁸ CARBONI	85 83	CNTR CNTR	

 32 The ASAI 94 limit is based on inclusive photon spectrum and is independent of A^0 decay

 33 The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0}<10^{-13}~m_{A^0}$ [keV] s. 34 ASAI 91 limit translates to $g_{A^0~e^+e^-}^2/4\pi<~1.1\times10^{-11}$ (90%CL) for $m_{A^0}<800$

35 The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of A^0 decay modes. $A^0 = \frac{1}{2} \left(\frac{1}{2} \right)^{1/2} = \frac{1}{2} \left(\frac{$

 $^{A'}$ decay modes. 36 ORITO 89 limit translates to $g_{A^0\,e\,e}^2/4\pi < 6.2\times 10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0} : $B<7.6\times 10^{-6}$ at 100 keV. 37 AMALDI 85 set limits $B(A^0\gamma)$ / $B(\gamma\gamma\gamma)<(1-5)\times 10^{-6}$ for $m_{A^0}=900$ –100 keV

which are about 1/10 of the CARBONI 83 limits.

 38 CARBONI 83 looked for orthopositronium $\to A^0 \gamma$. Set limit for A^0 electron coupling squared, $g(eeA^0)^2/(4\pi) < 6. \times 10^{-10}$ –7. $\times 10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from g–2 experiments.

A⁰ (Axion) Search in Photoproduction

DOCUMENT ID COMMENT

 39 BASSOMPIE... 95 $~m_{\ensuremath{A^0}} = 1.8 \pm 0.2 \; \mathrm{MeV}$

 39 BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of $e^+\,e^-$ pairs in the region $m_{\,e^+\,e^-}=1.8\pm0.2$ MeV. They obtained bounds on the production rate A^0 for $\tau(A^0)=10^{-18}\text{-}10^{-9}\,\text{sec}$. They also obtained bounds on the production rate A^0 for $\tau(A^0)=10^{-18}$ found an excess of events in the range $m_{e^+e^-}=2.1$ –3.5 MeV.

A0 (Axion) Production in Hadron Collisions

Limits are for $\sigma(A^0) / \sigma(\pi^0)$.

 $^{
m 40}\,{\rm BLUEMLEIN}$ 92 is a proton beam dump experiment at Serpukhov with a secondary

target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0 . See Fig. 5 for the excluded region in m_{A^0} -x plane. For the standard axion, 0.3 <x<25 is excluded at 95% CL. If combined with BLUEMLEIN 91, 0.008 <x<32 is excluded. 41 MEIJERDREES 92 give $\Gamma(\pi^-p \to nA^0)$ -B($A^0 \to e^+e^-$)/ $\Gamma(\pi^-p \to al)$) < 10-5 (90% CL) for $m_{A^0} = 100$ MeV, $\tau_{A^0} = 10^{-11}$ - 10^{-23} sec. Limits ranging from 2.5 × 10^{-3} to 10^{-7} are given for $m_{A^0} = 25$ -136 MeV. 10^{-3} to 10^{-7} are given for $m_{A^0} = 25-136$ MeV.

42 BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \rightarrow e^+e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0} -x plane ($x=\tan\beta=v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2$ MeV for most x>1, 0.2–11 MeV for most x<1. ⁴³ FAISSNER 89 searched for $A^0 \rightarrow e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e-20$

MeV is excluded. Lower limit on f_{A^0} of $\simeq 10^4$ GeV is given for $m_{A^0} = 2 m_e$ -20 MeV.

 44 DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass $\sim 1.1, \sim 2.1,$ and ~ 9 MeV, lifetimes 10^{-16} – 10^{-15} s decaying to e^+e^- and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A A22 183 (1953)). criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 898 is a reply which contests the criticism.

decay. DEBOLE 898 is a reply which contests the criticism. 45 EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 \pm 0.59 MeV, lifetime $(0.15\pm0.01)\times10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at \sim 4 GeV/c/nucleon. 46 FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event

for $A^0 \to \gamma \gamma$. A standard axion decaying to 2γ is excluded except for a region $x \simeq 1$. Lower limit on f_{A^0} of $10^2 - 10^3$ GeV is given for $m_{A^0} = 0.1 - 1$ MeV.

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- 47 BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range $m_{A^0}=$ (20–200) MeV, which excludes the A^0 decay constant $\mathit{f}(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$ - m_{A^0} plane.
- ⁴⁸BERGSMA 85 look for $A^0 \rightarrow 2\gamma$, e^+e^- , $\mu^+\mu^-$. First limit above is for $m_{A^0}=1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on $f_{A0} - m_{A0}$ plane, where f_{A0} is A^0 decay constant. For Peccel-Quinn PECCEI 77 A^0 , m_{A0} <180 keV and τ >0.037 s. (CL = 90%). For the axion of FAISSNER 818 at 250 keV, BERGSMA 85 expect 15 events but observe zero.

49 FAISSNER 83 observed 19 1-γ and 12 2-γ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.

50 FAISSNER 83B extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ 's are not at variance with LAMPF upper limit of 450 γ 's. Derived from LAMPF limit that $[\sigma r(A^0)/d\omega$ at $90^0]m_{A^0}/\tau_{A^0} < 14 \times 10^{-35}$ cm² sr⁻¹ MeV ms⁻¹. See

iimit that $\lfloor d\sigma(A^{\rm u})/d\omega$ at $90^{\rm o} \rfloor m_{A0}/\tau_{A0} < 14 \times 10^{-35}~{\rm cm}^2~{\rm sr}^{-1}$ MeV ms⁻¹. See comment on FRANK 838. 51 FRANK 838 stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ 's. See comment on FAISSNER 838. 40 FFMAN 83 set CL = 90% limit $d\sigma/dt$ B(e^+e^-) $< 3.5 \times 10^{-32}~{\rm cm}^2/{\rm GeV}^2$ for 140 $< m_{A0} < 160$ MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.

53 FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-γ peak rate remarkably decreases if iron wall is set in front of the decay

54 FAISSNER 81 see excess μe events. Suggest axion interactions.

 55 FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 \pm 5.0 events of 2γ decay of long-lived neutral penetrating particle with $m_{2\gamma}\lesssim$ 1 MeV. Axion interpretation with η - A^0 mixing gives $m_{A^0}=250\pm25$ keV, $\tau_{(2\gamma)}=(7.3\pm3.7)\times10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEKSEEV 82, CAVAIGNAC 83, and ANANEV 85. SEEV 82, CAVAIGNAC 83, and ANANEV 85. CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86 \sim 5.6) \times 10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200

axion production underestimated and mass overestimated. Correct value around 200

 $^{57}_{\rm KeV.S}^{\rm KeV.}$ RollsSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \rightarrow e^+e^-$ decay. Assuming $A^0/\pi^0=5.5\times 10^{-7}$, obtained decay rate limit $20/(A^0$ mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$

⁵⁸ JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interactaction}) < 7. \times 10^{-68}]$ cm⁴, CL = 90%]. Second limit is from nonobservation of axion decays into 2γ 's or e^+e^- , and for axion mass a few MeV. 59 SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.

60 BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^- . No signal found. CL = 90% limits for model parameter(s) are given.

61 COTEUS 79 is a beam dump experiment at BNL.

62 DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distri-

butions due to energy lost to weakly interacting particles. 63 BELLOTTI 78 first value comes from search for 40 \rightarrow $^{e+}e^-$. Second value comes from search for 40 \rightarrow $^{e+}e^-$. For any mass satisfying this,

limit is above value $\times (\text{mass}^{-4})$. Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67} \text{ cm}^4.$

64 BOSETTI 78B quotes $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67} \text{ cm}^4$.

65 DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.

66 MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).
67 VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A⁰ (Axion) Searches in Reactor Experiments

DOCUMENT ID TECN COMMENT ● ● • We do not use the following data for averages, fits, limits, etc. ● ● 95 CNTR Reactor; $A^0 \rightarrow e^+e^-$ ⁶⁸ ALTMANN 69 KETOV Reactor, $A^0 \rightarrow \gamma \gamma$ 86 SPEC 86 SPEC Reactor; $A^0 \rightarrow \gamma \gamma$ ⁷⁰ косн 71 DATAR 82 CNTR Light water reactor 72 VUILLEUMIER 81 CNTR Reactor, $A^0 \rightarrow 2\gamma$

- 68 ALTMANN 95 looked for A^0 decaying into e^+e^- from the Bugey 5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma) \times B(A^0)$ e+e-> $(10^{-16} \text{ for } m_{A^0} = 1.5 \text{ MeV}$ at 90% CL. The limit is weaker for heavier A^0 . In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0}, f_{X^0}) plane.
- 69 KETOV 86 searched for A^{0} at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of 0.8 [100 keV/ m_{A^0}]⁶ \times 10⁻⁶ per fission. In the standard axion model, this corresponds to $m_{A^0}~>$ 150 keV. Not valid for $m_{A^0}~\gtrsim$
- 70 $^{\rm I}$ MeV. 70 $^{\rm I}$ MeV. 70 $^{\rm I}$ MeV. 86 searched for $A^0 \to \gamma \gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} > 1022$

- 71 DATAR 82 looked for ${\it A}^0
 ightarrow 2\gamma$ in neutron capture (${\it np}
 ightarrow {\it d} {\it A}^0$) at Tarapur 500 MW reactor. Sensitive to sum of I=0 and I=1 amplitudes. With ZEHNDER 81 [(I=0)](I=1)] result, assert nonexistence of standard A^0 .
- 72 VUILLEUMIER 81 is at Grenoble reactor. Set limit m_{A^0} <280 keV.

A^0 (Axion) and Other Light Boson (X^0) Searches in Nuclear Transitions

- 73 TSUNODA 95 looked for axion emission when ²⁵²Cf undergoes a spontaneous fission, with the axion decaying into $e^+\,e^-$. The bound is for $m_{\mbox{$A^0$}}{=}$ 40 MeV. It improves to $\rm 2.5 \times 10^{-5}$ for $m_{A0}{=}200$ MeV.
- 74 MINOWA 93 studied chain process, 139 Ce \rightarrow 139 La* by electron capture and M1 transition of $^{139}\text{La}^*$ to the ground state. It does not assume decay modes of A^0 . The bound applies for $m_{A^{\scriptsize 0}} < 166$ keV.
- $^{75}\,\mathrm{HICKS}$ 92 bound is applicable for $\tau_{X^0}~<4\times10^{-11}$ sec.
- 76 The ASANUMA 90 limit is for the branching fraction of X^0 emission per $^{241}{\rm Am}\,\alpha$ decay and valid for $\tau_{X^0}~<~3\times 10^{-11}~{\rm s}.$
- ⁷⁷The DEBOER 90 limit is for the branching ratio 8 Be* (18.15 MeV, $^{1+}$) \rightarrow 8 Be 4 0, $A^0 \rightarrow e^+e^-$ for the mass range $m_{A^0} = 4$ –15 MeV.
- ⁷⁸ The BINI 89 limit is for the branching fraction of 16 O* (6.05 MeV, $^{0+}$) \rightarrow 16 O 0 , $X^0
 ightarrow e^+e^-$ for $m_X=$ 1.5–3.1 MeV. $au_{X^0} \lesssim 10^{-11}\,\mathrm{s}$ is assumed. The spin-parity
- of X is restricted to 0^+ or 1^- .

 79 AVIGNONE 88 looked for the 1115 keV transition $C^* \to CuA^0$, either from $A^0 \to 2\gamma$ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.
- ⁸⁰ DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \rightarrow e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13} – 10^{-8} s. The above limit is for $\tau=5\times 10^{-13}$ s and m=1.7 MeV; see the paper for the τ -m dependence of the
- ⁸¹ The limit is for the branching fraction of $^{16}O^*(6.05 \text{ MeV}, 0^+) \rightarrow ^{16}OX^0, X^0 \rightarrow$ $e^+\,e^-$ against internal pair conversion for $m_{\chi^0}=$ 1.7 MeV and $\tau_{\chi^0}~<~10^{-11}\,{\rm s}.$ Similar limits are obtained for $m_{\chi^0}=1.3$ –3.2 MeV. The spin parity of χ^0 must be either 0+ or 1-. The limit at 1.7 MeV is translated into a limit for the x^0 -nucleon coupling constant: $g_{\chi 0\,NN}^2/4\pi~<~2.3\times10^{-9}$.
- ⁸² The DOEHNER 88 limit is for $m_{A^0}=1.7$ MeV, $au(A^0)<10^{-10}$ s. Limits less than
- $^{A^0}$ are obtained for $m_{A^0}=1.2$ –2.2 MeV. 83 SAVAGE 88 looked for A^0 that decays into $e^+\,e^-$ in the decay of the 9.17 MeV $J^P=2^+$ state in 14 N, 17.64 MeV state $J^P=1^+$ in 8 Be, and the 18.15 MeV state $J^P=1^+$ in 8 Be. This experiment constrains the isovector coupling of A^0 to hadrons, if m_{A^0} = (1.1 \rightarrow 2.2) MeV and the isoscalar coupling of A^0 to hadrons, if $m_{A^0} = (1.1)^{-1}$ 2.6) MeV. Both limits are valid only if $\tau({\it A}^0) \lesssim 1 \times 10^{-11}$ s.
- 84 Limits are for $\Gamma(A^0(1.8~{\rm MeV}))/\Gamma(\pi{\rm M1})$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for au_{A^0} $< 2 imes 10^{-11} \mathrm{s}.$ $^6 ext{Li}$ isovector decay data strongly disfavor PECCEI 86 model I, whereas the ^{10}B and ^{14}N isoscalar decay data strongly reject PECCEI 86 model II and III.

Axions (A^0) and Other Very Light Bosons

- 85 SAVAGE 86B looked for A^0 that decays into $e^+\,e^-$ in the decay of the 9.17 MeV $J^P=$ 2+ state in 14 N. Limit on the branching fraction is valid if $\tau_{A^0}\lesssim$ 1. \times 10 $^{-11}{\rm s}$ for m_{A^0}
- = (1.1–1.7) MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons. 86 ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (Li* decay) and below $2m_e$ for deuteron* decay.
- 87 CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{\rm 97}{\rm Nb^*decay}$ and axion with $m_{\ensuremath{A^0}}$ between 275 and 288 keV (deuteron* decay).
- 88 ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard ${\it A}^{0}$ at CL = 95% mass-ranges $m_{A^{\scriptsize 0}}~<\!\!400$ keV (Li* decay) and 330 keV $<\!\!m_{A^{\scriptsize 0}}~<\!\!2.2$ MeV. (deuteron* decay).
- ⁸⁹ LEHMANN 82 obtained $A^0 \rightarrow 2\gamma$ rate $< 6.2 \times 10^{-5}/s$ (CL = 95%) excluding m_{A^0} between 100 and 1000 keV.

 90 ZEHNDER 82 used Goesgen 2.8GW light-water reactor to check A^0 production. No
- 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0 . Set limit m_{A^0} <60 keV for any
- 91 ZHNDER 81 looked for Ba* \rightarrow A^0 Ba transition with $A^0 \rightarrow 2\gamma$. Obtained 2γ coincidence rate $< 2.2 \times 10^{-5}/s$ (CL = 95%) excluding $m_{A^0} >$ 160 keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.
- 92 CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A⁰ (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \rightarrow e^+e^-)$

- $^{101}\,\text{HALLIN}$ 92 quote limits on lifetime, 8 \times 10 $^{-14}$ –5 \times 10 $^{-13}$ sec depending on mass, assuming B(A^0 $\to e^+e^-)=$ 100%. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.
- 102 HENDERSON 92C exclude axion with lifetime τ_{A0} =1.4 \times 10 $^{-12}$ –4.0 \times 10 $^{-10}$ s, assuming B($A^0\to e^+e^-$)=100%. HENDERSON 92c also exclude a vector boson with au=1.4 × 10^{-12} –6.0 × 10^{-10} s.
- 103 WU 92 quote limits on lifetime > 3.3 × 10⁻¹³ s assuming B($A^0 \rightarrow e^+e^-$)=100%. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.
- ¹⁰⁴WIDMANN 91 bound applies exclusively to the case B($A^0 \rightarrow e^+e^-$)=1, since the detection efficiency varies substantially as $\Gamma(A^0)_{\text{total}}$ changes. See their Fig. 6.
- 105 JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13} s $< \tau(A^0)$ $<7.5\times10^{-12}\,\mathrm{s}$ (95% CL) at $m_{A^0}=1.832$ MeV. Comparable limits can be set for $m_{A^0} = 1.776 - 1.856 \text{ MeV}.$
- 106 See also TSERTOS 88B in references.

 107 The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.
- 108 VANKLINKEN 88 looked for relatively long-lived resonance ($au=10^{-10}$ – 10^{-12} s). The
- sensitivity is not sufficient to exclude such a narrow resonance. 109 MAIER 87 obtained limits $R\Gamma\lesssim 60$ eV (100 eV) at $m_{A0}\simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\rm cm}\simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma=\Gamma_{e\,e}^2/\Gamma_{total}.$ For a discussion implying that $\Delta E_{\rm cm} \simeq 10$ keV, see TSERTOS 89.
- 110 VONWIMMERSPERG 87 measured Bhabha scattering for $E_{\rm cm}=1.37$ –1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{\rm cm}=14.5\pm6.8$ keV-b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

 τ^{135} BERNATOWICZ 92 studied double- β decays of τ^{128} Te and τ^{130} Te, and found the ratio τ^{130} Te)/ τ^{128} Te) = $(3.52\pm0.11)\times10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of τ^{128} Te of $(7.7\pm0.4)\times10^{24}$ year.

We calculated 90% CL limit as $(7.7-1.28\times0.4-7.2)\times10^{24}$. 136 TANAKA 93 also quote limit 5.3 $\times10^{19}$ years on two Majoron emission. 137 VERGADOS 82 sets limit $g_H < 4\times10^{-3}$ for (dimensionless) lepton-number violating coupling, g_H , of scalar boson (Majoron) to neutrinos, from analysis of data on double β decay of ^{48}Ca .

INVISIBLE A^0 (AXION)

As discussed in the note on "Axions and Other Light Bosons," the so-called invisible axion models decouple the scale of the Peccei-Quinn symmetry breaking from the electroweak scale, and avoid the constraints from negative accelerator searches for the axion. Two classes of models are discussed commonly in the literature. One introduces new heavy quarks that carry Peccei-Quinn charge while the usual quarks and leptons do not (KSVZ axions or "hadronic" axions) [1]. The other does not need additional quarks but requires two Higgs doublets, and all quarks and leptons carry Peccei-Quinn charges (DFSZ axions or "GUT" axions) [2]. All models contain at least one electroweak singlet scalar boson that acquires an expectation value and breaks the Peccei-Quinn symmetry.

The common property of all axion models is the effective coupling

$$\mathcal{L} = \left(\theta_{\text{eff}} - \frac{\phi_A}{f_A}\right) \frac{g_s^2}{32\pi^2} F^{\mu\nu a} \widetilde{F}^a_{\mu\nu} , \qquad (1)$$

where ϕ_A is the axion field, θ_{eff} is the effective QCD vacuum angle after the diagonalization of the quark masses, g_s the QCD coupling constant, $F^{\mu\nu a}$ the gluon field strength and $\widetilde{F}^a_{\mu\nu}=$ $\frac{1}{2}\epsilon_{\mu\nu\rho\sigma} F^{\rho\sigma a}$. It is often convenient to define the axion decay constant f_A with this Lagrangian [3]. The QCD instanton effect induces a potential for ϕ_A whose minimum is at $\phi_A = \theta_{eff} f_A$, cancelling θ_{eff} and solving the strong CP problem. The mass of the axion is related to f_A by

$$m_A = 0.62 \times 10^{-3} \text{eV} \times (10^{10} \text{GeV}/f_A) \ .$$
 (2)

The constraints on the axion mass from various experiments, astrophysics, and cosmology are derived from the interactions of the axion with either photons, electrons, or nucleons. We use the following notation for their coupling constants $G_{A\gamma\gamma}$ and

$$\mathcal{L}_{A\gamma\gamma} = -\frac{1}{4} G_{A\gamma\gamma} \phi_A F^{\mu\nu} \widetilde{F}_{\mu\nu} = G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B} , \qquad (3)$$

$$\mathcal{L}_{Aff} = G_{Aff} \, \partial_{\mu} \phi_A \, \overline{f} \gamma^{\mu} \gamma_5 \, f \, , \tag{4}$$

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

for f = e, p, n. The relations of these coupling constants to f_A (and m_A) are model dependent, and are listed in Table 1.

Table 1: The coupling constants of the axion to the matter particles in DFSZ and KSVZ models, taken from Ref. [5] where the results of Ref. [6] were used. These dimensionless coupling constants are related to those in the Lagrangian by $G_{Aii} = c_i/2f_A$ for $i = \gamma, e, p, n$. The parameter β is an arbitrary angle whose tangent is defined by the ratio between the expectation values of the two Higgs doublets in the DFSZ model. A rational number E/N in the KSVZ model depends on the number of new quarks and their charges. The coupling to nucleons are subject to certain ambiguities in hadronic matrix elements [4] that are not shown here. All entries have small uncertainties from the current quark masses.

	DFSZ	KSVZ
$\overline{c_{\gamma}}$	0.0017	0.0023(E/N - 1.92)
c_e	$(1/3)\cos^2\beta$	0
c_p	$-0.10 - 0.45\cos^2\beta$	-0.39
c_n	$-0.18 + 0.39\cos^2\beta$	+0.04

For illustrative purposes, we depict various constraints on f_A (and m_A) for the case of the KSVZ model in Fig. 1, using only representative constraints. What follows is a brief discussion of each of the constraints shown in the figure. The bounds on the DFSZ axion are similar.

Astrophysics puts a lower bound on f_A , because a small f_A leads to a large coupling of the axion to nucleons, electrons, and photons and thus to a large "exotic" energy-loss rate. In horizontal-branch (HB) stars, the Primakoff process γ + $(^4He, e^-) \rightarrow (^4He, e^-) + A^0$ would be the dominant axionic energy-loss mechanism. It would accelerate the consumption of nuclear fuel and thus shorten the helium-burning lifetime of these stars. The observable number fraction of HB stars in globular clusters would be significantly reduced relative to theoretical expectations unless $G_{A\gamma\gamma} < 0.6 \times 10^{-10} \text{ GeV}^{-1}$ [5]. The duration of the neutrino burst from supernova (SN) 1987A observed at the Kamiokande and IMB detectors was consistent with expectations, while axion emission would have cooled the core and shortened the burst duration [7]. The dominant emission process is axion bremsstrahlung in nucleonnucleon collisions, a process that needs to be calculated in a hot and dense nuclear medium where many-body effects are important. Early calculations overestimated the emission rate to some extent. A more realistic treatment leads to a somewhat diminished limit of about $f_A > 0.6 \times 10^9$ GeV [8], [9], although the treatment of many-body effects in this result is still under study. The cooling argument does not exclude $f_A \lesssim 0.6 \times 10^6$ GeV; in this range of f_A , the axions produced in the SN core are trapped [10]. Still, $f_A \lesssim 0.3 \times 10^6$ GeV is excluded because the trapped axions result in a burst similar to that of the neutrinos and can produce signals in water

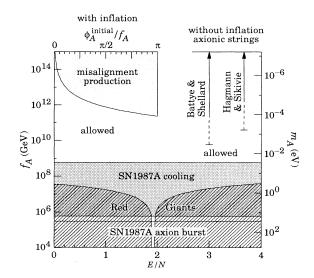

Figure 1: An illustration of the astrophysical and cosmological constraints on the axion decay constant f_A (and equivalently on m_A) in the KSVZ model. The constraint on the DSFZ model is similar except for the small window at $f_A \sim 10^6$ GeV, and one needs inflation. Shaded regions are excluded based on the arguments given in the text, though both sides have large uncertainties. The lower bound on f_A from red giants depends on the parameter E/N. All the other constraints do not. If there is inflation, there is an upper bound on f_A from misalignment production, which depends on the initial value of the axion field $\phi_A^{\rm initial}$ after inflation is over. If there is not, cosmic strings generated by Peccei-Quinn symmetry breaking produce axions, which contribute to the present mass density. Estimates of the resulting mass density vary. Here, upper bounds on f_A from two groups are shown, each of them with rather large ambiguity shown by dashed lines.

Cherenkov detectors [11]. For KSVZ axions with $E/N \approx 2$, there exists an apparent small window between these two SN arguments.

Cosmology usually puts an upper bound on f_A , because the predicted cosmic mass density in axions is proportional to $f_A^{1.175}$. The DFSZ model and the KSVZ model with more than one new quark leads to domain walls that have to be diluted away by inflation. On the other hand, the axion field does not know during inflation where the true minimum of its potential is, and is "misaligned" [12]. It begins a coherent oscillation from its misaligned initial value after the QCD phase transition and contributes to the present energy density [13] as $\Omega_a h^2 \simeq 0.2 (f_A/10^{12} \text{ GeV})^{1.175} (\phi_A^{\text{initial}}/2\pi f_A)^2 \leq 1$ for a small misalignment $\phi_A^{\text{initial}}/f_A \lesssim 1$. The KSVZ model with a single new quark does not produce domain walls and does not need inflation. Without inflation, there are cosmic strings created at

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

the time of the Peccei–Quinn symmetry breaking, that emit axions and eventually decay (or collapse). There is an ongoing controversy on the estimate of the relic energy density of the emitted axions [14]. Furthermore, cosmological bounds change if there is additional entropy production [15] or a dissipation of the coherent oscillation into lighter particles [16].

It has been widely argued that a fundmental theory will not possess global symmetries; gravity, for example, is expected to violate them. Global symmetries such as baryon number typically arise as an indirect consequence of gauge symmetries and renormalizability (accidental symmetry). It has been noted [17] that the Peccei-Quinn symmetry, from this perspective, must also arise as an accidental one and must hold to an extraordinary degree of accuracy in order to solve the strong CP problem. See, for example, Ref. [17] for a possible resolution to this problem; string theory also provides sufficiently good symmetries (see for a review, [18]).

Invisible A⁰ (Axion) MASS LIMITS from Astrophysics and Cosmology

 $v_1=v_2$ is usually assumed ($v_i=$ vacuum expectation values). For a review of these limits, see RAFFELT 90C and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview. DE(eV) DOCUMENTID TECN COMMENT

- 138 RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).
- 139 ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5 \times 10^{-13}$, from energy loss via axion emission. 140 BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2 γ
- 140 BERSHADY 91 searched for a line at wave length from 3100–8300 Λ expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies. 141 KIM 91C argues that the bound from the mass density of the universe will change dras-
- 141 KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an upperbound rather than a lowerbound.
- 142 RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.
- 143 RESSELL 91 uses absence of any intracluster line emission to set limit.

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- 144 ENGEL 90 rule out $10^{-10}\lesssim$ $g_{AN}\lesssim10^{-3},$ which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to 2.5×10^{-3} eV $\lesssim m_{A^0} \lesssim 2.5 \times 10^{-3}$ 10⁴ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.
- 145 RAFFELT 90D is a re-analysis of DEARBORN 86.
- 146 The region $m_{A^0} \gtrsim$ 2 eV is also allowed.
- 147 ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.
- 148 MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2-4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 888.
- 149 RAFFELT 888 derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100$ erg g $^{-1}$ s $^{-1}$, which gives a firmer basis for the axion limits based on red giant cooling.
- $^{150}\,\mathrm{RAFFELT}$ 87 also gives a limit $g_{A\gamma}~<~1\times10^{-10}~\mathrm{GeV}^{-1}.$
- $^{151}\,\mathrm{DEARBORN}$ 86 also gives a limit $g_{A\gamma}~<~1.4\times10^{-11}~\mathrm{GeV}^{-1}.$
- 152 RAFFELT 86 gives a limit $g_{A\gamma}~<~1.1\times10^{-10}~{\rm GeV}^{-1}$ from red giants and $<2.4\times10^{-9}$
- $\rm GeV^{-1}$ from the sun. 153 KAPLAN 85 says $m_{A^0} <$ 23 eV is allowed for a special choice of model parameters.
- 154 FUKUGITA 82 gives a limit $g_{A\gamma}~<~2.3 \times 10^{-10}~{\rm GeV}^{-1}$.

Search for Relic Invisible Axions

Limits are for $[{\it G_{A\gamma\gamma}}/m_{A^0}]^2 \rho_A$ where ${\it G_{A\gamma\gamma}}$ denotes the axion two-photon coupling, $L_{\mathrm{int}}=rac{G_{A\gamma\gamma}}{4}\phi_AF_{\mu\nu}\widetilde{F}^{\mu\nu}=G_{A\gamma\gamma}\phi_A\mathbf{E}\cdot\mathbf{B}$, and ho_A is the axion energy density near the earth.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT

$< 2 \times 10^{-41}$		¹⁵⁵ HAGMANN	90	CNTR	$m_{A^0} =$
<1.3 × 10 ⁻⁴²	95	¹⁵⁶ WUENSCH	89	CNTR	$(5.4-5.9)10^{-6} \text{ eV}$ $m_{A^0} = (4.5-10.2)10^{-6}$
$< 2 \times 10^{-41}$	95	¹⁵⁶ WUENSCH			$m_{A^0}^{\text{ev}} =$
					(** 0 ** 0)*0-6 .)/

155 HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

156 WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2=$ with $[G_{A\gamma\gamma}/m_{A0}]^2=2\times 10^{-14}~{
m MeV}^{-4}$ (the three generation DFSZ model) and $\rho_A=300~{
m MeV}/{
m cm}^3$ that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A0})^2~\rho_A=4\times 10^{-44}.$ Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A⁰ (Axion) Limits from Photon Coupling

Limits are for the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L=G_{A\gamma\gamma}\phi_A {f E}\cdot {f B}.$ Related limits from astrophysics can be found in the "Invisible A⁰ (Axion) Mass Limits from Astrophysics and Cosmology" section.

- 162 These experiments measured induced magnetization of a bulk material by the spindependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.
- These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either
- 164 WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

LEPTONS

e

 $J = \frac{1}{2}$

e MASS

The mass is known much more precisely in u (atomic mass units) than in MeV (see the footnote). The conversion from u to MeV, $1\,u=931.49432\pm0.00028$ MeV, involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
0.51099907±0.00000015	¹ FARNHAM	95	CNTR	Penning
• • We do not use the follow	wing data for average	s, fits	s, limits,	etc. • •
$0.51099906 \pm 0.00000015$	² COHEN	87	RVUE	1986 CODATA value
0.5110034 ± 0.0000014	COHEN	73	RVUE	1973 CODATA value

1 FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}\text{C}^{+6}$ ion. The result is $m_e=0.0005485799111(12)\,\text{u}$, where the figure in parenthesis is the 1σ uncertainty in the last digit. The uncertainty after conversion to MeV is dominated by the uncertainty in the electron charge.

² COHEN 87 (1986 CODATA) value in atomic mass units is 0.000548579903(13). See footnote on FARNHAM 95.

$$(m_{e^+}-m_{e^-}) / m_{\rm average}$$

A test of CPT invariance.

 $^{\rm 8}$ ABDULLAH 90 uses the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

e MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45**, 1 June, Part II (1992), p. VI.10). We use the best "disappearance" limit for the Summary Tables. The best limit for the specific channel $e^- \to \nu \gamma$ is much better.

Note that we use the mean life rather than what is often reported, the half life.

tios.

MUELLER 92 argues that an inequality of the charge magnitudes would, through higher-order vacuum polarization, contribute to the net charge of atoms.

 $J = \frac{1}{2}$

μ MASS

The mass is known more precisely in u (atomic mass units) than in MeV (see the footnote to COHEN 87). The conversion from u to MeV, 1 u 931.49432 ± 0.00028 MeV, involves the relatively poorly known electronic

Where $m_{\mu}/m_{\rm e}$ was measured, we have used the 1986 CODATA value for $m_{\rm e}=0.51099906\pm0.00000015$ MeV.

10 COHEN 87 (1986 CODATA) value was fitted using their own selection of the following data. Because their value is from a multiparameter fit, correlations with other quantities may be important and one cannot arrive at this result by any average of these data alone.

μ- DECAY MODES

 μ^+ modes are charge conjugates of the modes below.

	Mode		Fraction ((F _i /F)	Confidence	level
Γ ₁	$e^- \overline{\nu}_e \nu_\mu$		≈ 100%			
	$e^- \overline{\nu}_e \nu_\mu \gamma$		[a] (1.4±0	0.4) %		
Γ3	$e^-\overline{ u}_e u_\mue^+e^-$		[b] (3.4±0	$0.4) \times 10^{-5}$		
	Lepton Far	nily number (LF) violatir	ng modes		
Γ_4	$e^- \nu_e \overline{\nu}_\mu$	LF	[c] < 1.2	%		90%
Γ_5	$e^-\gamma$	LF	< 4.9	$\times 10^{-11}$		90%
Γ_6	$e^{-}e^{+}e^{-}$	LF	< 1.0	$\times 10^{-12}$		90%
Γ7	$e^- 2\gamma$	LF	< 7.2	$\times 10^{-11}$		90%

- [a] This only includes events with the γ energy > 10 MeV. Since the $e^-\,\overline{\nu}_e\,\nu_\mu$ and $e^-\,\overline{
 u}_e\,
 u_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [b] See the Particle Listings below for the energy limits used in this measure-
- [c] A test of additive vs. multiplicative lepton family number conservation.

²⁴GORDEEV 94 quote limits on both $f=G_{M\overline{M}}/G_F$ and on the probability $W_{M\overline{M}}$ 5.1×10^{-7} (90% CL). Final results are based on the full data set.

MUON DECAY PARAMETERS

(by W. Fetscher and H.-J. Gerber, ETH Zürich)

All measurements in direct muon decay, $\mu^- \rightarrow e^- + 2$ neutrals, and its inverse, $\nu_{\mu} + e^{-} \rightarrow \mu^{-} + \text{neutral}$, are successfully described by the "V-A interaction," which is a particular case of a local, derivative-free, lepton-number-conserving, four-fermion interaction [1]. The matrix element is given below. The $V\!-\!A$ form and the nature of the neutrals $(\nu_{\mu}$ and $\overline{\nu}_{e})$, and hence the doublet assignments $(\nu_e \ e^-)_L$ and $(\nu_\mu \ \mu^-)_L$, can be determined from experiments [2,3].

All results in direct muon decay (energy spectra, polarizations, and angular distributions) and in inverse muon decay (the reaction cross section) at energies well below $m_W c^2$ may be

 μ

parametrized in terms of amplitudes $g_{\varepsilon\mu}^{2}$ and the Fermi coupling constant G_{F} , using the matrix element

$$\frac{4G_F}{\sqrt{2}} \sum_{\substack{\gamma = S, V, T\\ \epsilon, \mu = R}} g_{\epsilon\mu}^{\gamma} \langle \overline{e}_{\epsilon} \mid \Gamma^{\gamma} \mid (\nu_e)_n \rangle \langle (\overline{\nu}_{\mu})_m \mid \Gamma_{\gamma} \mid \mu_{\mu} \rangle . \tag{1}$$

We use the notation of Fetscher et al. [2], who in turn use the sign conventions and definitions of Scheck [4]. Here $\gamma = S, V, T$ indicate a scalar, vector, or tensor interaction; and $\varepsilon, \mu = R, L$ indicate a right- or left-handed chirality of the electron or muon. The chiralities n and m of the ν_e and $\overline{\nu}_{\mu}$ are then determined by the values of γ, ε , and μ . The particles are represented by fields of definite chirality [5].

As shown by Langacker and London [6], explicit lepton-number nonconservation still leads to a matrix element equivalent to Eq. (1). They conclude that it is not possible, even in principle, to test lepton-number conservation in (leptonic) muon decay if the final neutrinos are massless and are not observed.

The ten complex amplitudes $g_{\varepsilon\mu}^{\gamma}$ (g_{RR}^{T} and g_{LL}^{T} are identically zero) and G_{F} constitute 19 independent (real) parameters to be determined by experiment. The V-A interaction corresponds to the single amplitude g_{LL}^{V} being unity and all the others being zero.

C. Jarlskog [7] has noted that certain experiments observing the decay electron are especially informative if they yield the V-A values. Indeed, all (direct) muon decay experiments are compatible with an arbitrary mix of the scalar and vector amplitudes g_{LL}^S and g_{LL}^V —in the extreme, even with the purely scalar $g_{LL}^S = 2$, $g_{LL}^V = 0$. The decision in favor of V-A comes from the quantitative observation of inverse muon decay, which would be forbidden for pure g_{LL}^S [2].

The differential decay probability to obtain an e^{\pm} with (reduced) energy between x and x+dx, emitted in the direction \widehat{z} at an angle between θ and $\theta+d\theta$ with respect to the muon polarization vector \vec{P}_{μ} , and with its spin pointing in the arbitrary direction $\widehat{\zeta}$, is given by

$$\begin{split} \frac{d^2\Gamma}{dx\;d\cos\theta} &= \frac{m_\mu}{4\pi^3}\,W_{e\mu}^4\,G_F^2\,\sqrt{x^2-x_0^2} \\ &\quad \times \left(F_{IS}(x)\pm P_\mu\cos\theta\,F_{AS}(x)\right) \\ &\quad \times \left[1+\vec{P}_e(x,\theta)\cdot\widehat{\zeta}\right]\,. \end{split}$$

Here $W_{e\mu} = \max(E_e) = (m_{\mu}^2 + m_e^2)/2m_{\mu}$ is the maximum e^{\pm} energy, $x = E_e/W_{e\mu}$ is the reduced energy, and $x_0 = m_e/W_{e\mu} = 9.67 \times 10^{-3}$. The quantity $P_{\mu} = |\vec{P}_{\mu}| \cdot \hat{\zeta}$ has the significance of the direction in which a perfect polarization-sensitive electron detector would be most sensitive. The isotropic part of the spectrum, $F_{IS}(x)$, the anisotropic part, $F_{AS}(x)$, and the electron polarization, $\vec{P}_e(x,\theta)$, depend on bilinear combinations—called

decay parameters—of the coupling constants $g_{\varepsilon\mu}^{\gamma}$. Neglecting possible nonzero neutrino masses, we have, in terms of the decay parameters ρ , η , ξ , δ , etc.,

$$\begin{split} F_{IS}(x) &= x(1-x) + \frac{2}{9}\rho(4x^2 - 3x - x_0^2) + \eta \, x_0(1-x) \\ F_{AS}(x) &= \frac{1}{3}\xi \, \sqrt{x^2 - x_0^2} \\ &\qquad \times \left[1 - x + \frac{2}{3}\delta\Big(4x - 3 - (\sqrt{1 - x_0^2} - 1)\Big) \right] \\ \vec{P}_e(x,\theta) &= P_{T_1}\, \hat{x} + P_{T_2}\, \hat{y} + P_L\, \hat{z} \; . \end{split}$$

Here \widehat{x} , \widehat{y} , and \widehat{z} are orthogonal unit vectors defined as follows:

 \hat{z} is along the e momentum

 $\widehat{y} = [\widehat{z} \times \vec{P_{\mu}}]/|[\widehat{z} \times \vec{P_{\mu}}]|$ is transverse to the e momentum and perpendicular to the "decay plane" $\widehat{x} = \widehat{y} \times \widehat{z} \quad \text{is transverse to the } e \text{ momentum and in the "decay plane."}$

The components of \vec{P}_e then are given by

$$\begin{split} P_{T_1}(x,\theta) &= P_{\mu} \sin \theta \, F_{T_1}(x) \Big/ \Big(F_{IS}(x) \pm P_{\mu} \cos \theta \, F_{AS}(x) \Big) \\ P_{T_2}(x,\theta) &= P_{\mu} \sin \theta \, F_{T_2}(x) \Big/ \Big(F_{IS}(x) \pm P_{\mu} \cos \theta \, F_{AS}(x) \Big) \\ P_{L}(x,\theta) &= \pm F_{IP}(x) + P_{\mu} \cos \theta \\ &\qquad \times F_{AP}(x) \Big/ \Big(F_{IS}(x) \pm P_{\mu} \cos \theta \, F_{AS}(x) \Big) \;, \end{split}$$

where

$$F_{T_1}(x) = \frac{1}{12} \left\{ -2 \left[\xi'' + 12(\rho - \frac{3}{4}) \right] (1 - x) x_0 - 3\eta(x^2 - x_0^2) + \eta''(-3x^2 + 4x - x_0^2) \right\}$$

$$F_{T_2}(x) = \frac{1}{3} \sqrt{x^2 - x_0^2} \left\{ 3 \frac{\alpha'}{A} (1 - x) + 2 \frac{\beta'}{A} \sqrt{1 - x_0^2} \right\}$$

$$F_{IP}(x) = \frac{1}{54} \sqrt{x^2 - x_0^2} \left\{ 9 \xi' \left(-2x + 2 + \sqrt{1 - x_0^2} \right) + 4 \xi (\delta - \frac{3}{4}) \left(4x - 4 + \sqrt{1 - x_0^2} \right) \right\}$$

$$F_{AP}(x) = \frac{1}{6} \left\{ \xi''(2x^2 - x - x_0^2) + 4(\rho - \frac{3}{4}) (4x^2 - 3x - x_0^2) + 2 \eta''(1 - x) x_0 \right\}.$$

For the experimental values of the decay parameters ρ , ξ , ξ' , ξ'' , δ , η , η'' , α/A , β/A , α'/A , β'/A , which are not all independent, see the Data Listings below. Experiments in the past have also been analyzed using the parameters a, b, c, a', b', c', α/A , β/A , α'/A , β'/A (and $\eta = (\alpha - 2\beta)/2A$), as defined by Kinoshita and Sirlin [8]. They serve as a model-independent

summary of all possible measurements on the decay electron (see Listings below). The relations between the two sets of parameters are

$$\begin{split} \rho - \frac{3}{4} &= \frac{3}{4}(-a+2c)/A \;, \\ \eta &= (\alpha-2\beta)/A \;, \\ \eta'' &= (3\alpha+2\beta)/A \;, \\ \delta - \frac{3}{4} &= \frac{9}{4} \cdot \frac{(a'-2c')/A}{1-[a+3a'+4(b+b')+6c-14c']/A} \;, \\ 1 - \xi \frac{\delta}{\rho} &= 4 \frac{[(b+b')+2(c-c')]/A}{1-(a-2c)/A} \;, \\ 1 - \xi' &= [(a+a')+4(b+b')+6(c+c')]/A \;, \\ 1 - \xi'' &= (-2a+20c)/A \;, \end{split}$$

where

$$A = a + 4b + 6c.$$

The relations to the coupling constants are:

$$\begin{split} a &= 16(|g_{RL}^V|^2 + |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 + |g_{LR}^S + 6g_{LR}^T|^2 \;, \\ a' &= 16(|g_{RL}^V|^2 - |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 - |g_{LR}^S + 6g_{LR}^T|^2 \;, \\ \alpha &= 8\operatorname{Re}\left[g_{RL}^V(g_{LR}^S + 6g_{LR}^T)^* + g_{LR}^V(g_{RL}^S + 6g_{RL}^T)^*\right] \;, \\ \alpha' &= 8\operatorname{Im}\left[-g_{LR}^V(g_{RL}^S + 6g_{RL}^T)^* - g_{RL}^V(g_{LR}^S + 6g_{LR}^T)^*\right] \;, \\ b' &= 4(|g_{RR}^V|^2 + |g_{LL}^V|^2) + |g_{RR}^S|^2 + |g_{LL}^S|^2 \;, \\ b' &= 4(|g_{RR}^V|^2 - |g_{LL}^V|^2) + |g_{RR}^S|^2 - |g_{LL}^S|^2 \;, \\ \beta &= -4\operatorname{Re}\left[g_{RR}^V(g_{LL}^S)^* + g_{LL}^V(g_{RR}^S)^*\right] \;, \\ \beta' &= 4\operatorname{Im}\left[g_{RR}^V(g_{LL}^S)^* - g_{LL}^V(g_{RR}^S)^*\right] \;, \\ c &= \frac{1}{2}\left[|g_{RL}^S - 2g_{RL}^T|^2 + |g_{LR}^S - 2g_{LR}^T|^2\right] \;, \\ c' &= \frac{1}{2}\left[|g_{RL}^S - 2g_{RL}^T|^2 - |g_{LR}^S - 2g_{LR}^T|^2\right] \;. \end{split}$$

If also the electron mass is neglected, the energy and angular distribution of the electron in the rest frame of a polarized muon (μ^{\mp}) is given by the Michel spectrum:

$$\begin{split} d^2\Gamma \sim &\left\{3(1-x) + \frac{2\rho}{3}(4x-3)\right. \\ \mp &\xi \, \cos\theta[1-x + \frac{2\delta}{3}(4x-3)]\right\} x^2 dx \, d(\cos\theta) \ . \end{split}$$

Here θ is the angle between the electron momentum and the muon spin, and $x \equiv 2E_e/m_\mu$. For pure V-A coupling, we obtain $\rho = \xi \delta = 3/4$, $\xi = 1$, and the differential decay rate is

$$d^{2}\Gamma = \frac{G_{F}^{2}m_{\mu}^{5}}{192\pi^{3}} \left[3 - 2x \pm \cos\theta (1 - 2x) \right] x^{2} dx d(\cos\theta)$$

Here the coefficient in front of the square bracket is the total decay rate.

In order to determine the amplitudes $g_{\varepsilon\mu}^{\gamma}$ uniquely from experiment, Fetscher *et al.* [2] introduced four probabilities $Q_{\varepsilon\mu}(\varepsilon,\mu=R,L)$ for the decay of a μ -handed muon into an ε -handed electron and showed that there exist upper bounds on Q_{RR} , Q_{LR} , and Q_{RL} , and a lower bound on Q_{LL} . These probabilities are given in terms of the $g_{\varepsilon\mu}^{\gamma}$'s by

$$Q_{\varepsilon\mu} = \frac{1}{4} |g_{\varepsilon\mu}^S|^2 + |g_{\varepsilon\mu}^V|^2 + 3(1 - \delta_{\varepsilon\mu})|g_{\varepsilon\mu}^T|^2 , \qquad (2)$$

where $\delta_{\varepsilon\mu}=1$ for $\varepsilon=\mu$ and $\delta_{\varepsilon\mu}=0$ for $\varepsilon\neq\mu$. They are related to the parameters $a,\,b,\,c,\,a',\,b',$ and c' by

$$\begin{split} Q_{RR} &= 2(b+b')/A \ , \\ Q_{LR} &= [(a-a')+6(c-c')]/2A \ , \\ Q_{RL} &= [(a+a')+6(c+c')]/2A \ , \\ Q_{LL} &= 2(b-b')/A \ , \end{split}$$

with A = 16. In the pure V-A theory, $Q_{LL} = 1$ and the others are zero.

Since the upper bounds on Q_{RR} , Q_{LR} , and Q_{RL} are found to be small, and since the helicity of the ν_{μ} in pion decay is known from experiment [9,10] to very high precision to be -1 [11], the cross section S of *inverse* muon decay, normalized to the V-A value, yields [2]

$$|g_{LL}^S|^2 \le 4(1-S) \tag{3}$$

and

$$|g_{LL}^V|^2 = S (4)$$

Thus the Standard Model assumption of a pure V-A leptonic charged weak interaction for e and μ is confirmed (within errors) by experiments at energies far below the mass of the W^{\pm} : Eq. (4) gives a lower limit for V-A, and Eqs. (2) and (3) give upper limits for the other four-fermion interactions. The existence of such upper limits may also be seen from $Q_{RR} + Q_{RL} = (1 - \xi')/2$ and $Q_{RR} + Q_{LR} = \frac{1}{2}(1 + \xi/3 - 16\xi\delta/9)$. Table 1 gives the current experimental limits on the magnitudes of the $g_{\varepsilon\mu}^{\varepsilon}$'s.

Table 1. Ninety-percent confidence level experimental limits for the coupling constants $g_{\epsilon\mu}^{\gamma}$. The limits on $|g_{LL}^{S}|$ and $|g_{LL}^{V}|$ are from Ref. 12, and the others are from Ref. 13. The experimental uncertainty on the muon polarization in pion decay is included.

$ g_{RR}^S < 0.066$	$ g_{RR}^{V} < 0.033$	$ g_{RR}^T \equiv 0$
$ g_{LR}^S <0.125$	$ g_{LR}^{V} < 0.060$	$ g_{LR}^T < 0.036$
$ g_{RL}^S <0.424$	$ g_{RL}^V <0.110$	$ g_{RL}^{T} < 0.122$
$ g_{LL}^S <0.55$	$ g_{LL}^V > 0.96$	$ g_{LL}^T \equiv 0$

Limits on the "charge retention" coordinates, as used in the older literature (e.g., Ref. 14), are given by Burkard $et\ al.$ [15].

>0.9959	90	CARR	83	SPEC	+	11 kG	

 34 JODIDIO 86 includes data from CARR 83 and STOKER 85. The value here is from the

erratum. 35 STOKER 85 find $(\xi P_{\mu} \delta/\rho)$ >0.9955 and >0.9966, where the first limit is from new μ spin-rotation data and the second is from combination with CARR 83 data. In V-A theory, $(\delta/\rho)=1.0.$

$\xi' = \text{LONGITUDINAL POLARIZATION OF } e^+$

(V-A) theory predicts the longitudinal polarization $=\pm 1$ for e^\pm , respectively. We have flipped the sign for e so our programs can average.

 τ

 $J = \frac{1}{2}$

 τ discovery paper was PERL 75. $e^+e^-\to \tau^+\tau^-$ cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out J=3/2. KIRKBY 79 also ruled out $J\!=\!$ integer, J=3/2.

1776.9 $^{+0.4}_{-0.5}$ ± 0.2	14	⁵ BAI	92 BES	Repl. by BAI 96
¹ BAI 96 fit $\sigma(e^+e^-$				nreshold.

- ² BALEST 93 fit spectra of minimum kinematically allowed τ mass in events of the type $e^+e^- \to \tau^+\tau^- \to (\pi^+n\pi^0\nu_{\tau})(\pi^-m\pi^0\nu_{\tau})$ $n \leq 2$, $m \leq 2$, $1 \leq n+m \leq 3$. If $m_{\nu_{\tau}} \neq 0$, result increases by $(m_{\nu_{\tau}}^2/1100 \text{ MeV})$.
- 3 ALBRECHT 92M fit τ pseudomass spectrum in $\tau^-\to 2\pi^-\pi^+\nu_\tau$ decays. Result assumes $m_{\nu_\tau}{=}0.$
- 4 BACINO 78 alue comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(25)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.
- ⁵BAI 92 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ near threshold using $e\,\mu$ events.

au MEAN LIFE

A consistent treatment of systematic biases (see WASSERBAECH 93) yields a correction of $-0.03\,\mathrm{fs}$ on the average. In addition, BATTLE 92 assumes an obsolete value of the τ mass; the correction to be applied to the average is $-0.01\,\mathrm{fs}$. These corrections do not change the result within rounding errors, so that OUR EVALUATION is equal to OUR AVERAGE.

au^- DECAY MODES

 au^+ modes are charge conjugates of the modes below. " h^\pm " stands for π^\pm or K^\pm . " ℓ " stands for e or μ . "Neutral" means neutral hadron whose decay products include γ 's and/or π^0 's.

CONSTRAINED FIT INFORMATION

An overall fit to 57 branching ratios uses 128 measurements and one constraint to determine 25 parameters. The overall fit has a $\chi^2=115.2$ for 104 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left<\delta \kappa_i \delta \kappa_j\right>/(\delta \kappa_i \cdot \delta \kappa_j)$, in percent, from the fit to the branching fractions, $\kappa_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the κ_i whose labels appear in this array to sum to one.

au BRANCHING FRACTIONS

(by K.G. Hayes, Hillsdale College)

Significant improvements in experimental measurements of τ branching fractions have been made since the 1994 edition of these Listings. Measurements of many new branching fractions of 1-prong τ decays containing charged and/or neutral kaons have been published [1–6]. Other new high-precision measurements of other τ branching fractions have also appeared, including many by the ALEPH collaboration [6] that are more precise than the 1994 world averages. Consequently, there are many new branching fractions in the Listings. The number of conventional τ -decay modes has increased from 59 in the 1994 edition to 98 in the current edition, and most τ branching fractions now have an absolute uncertainty in the range of 0.1 to 0.2%, with improvements over the 1994 edition typically being a factor of two or more.

Our goal for internal consistency of the τ Listings is now at the 0.1% level. To add correctly a new experimental measurement of a branching fraction to the Listings, we must understand and account for the experimenter's definition of both the signal and any background corrections to it at the 0.1% level or better. This requires that many details be considered. Some examples are: (a) is $K_S^0 \to \pi^+\pi^-$ considered to be 0-prong or 2-prong; (b) are K_L^0 's included or excluded in a decay mode definition; (c) are $K_S^0 \to 2\pi^0$ decays background or signal; (d) how are photons from the decays of η and ω treated; (e) have particle ID requirements been applied to any charged prongs (either through direct detection or indirectly via cuts on invariant mass distributions); and (f) exactly what is meant by the word "neutral" in a decay mode definition?

The τ Listings have been updated in several ways to accommodate the new measurements and the need for higher precision. To help make explicit how the signal and background are defined, we have developed new notation for listing decay modes. First, invisible K_L^0 's are never implicitly included in any decay mode (this is a change from previous editions). Second, for decay modes where contributions from an intermediate state are excluded, a list is appended to the decay mode which explicitly gives the excluded intermediate states. For this edition, the only intermediate states whose decays are excluded from some branching fractions are K^0 , η , and ω . If there is no ambiguity as to which intermediate state decay modes are excluded, just the name of the intermediate state is given. Otherwise, the excluded intermediate state decay mode is explicitly listed. The list is appended to the decay mode using the notation "(ex. (list of excluded intermediate states))." For example, listed in Table 1 are a few decay modes from the current Listings and their fitted branching fractions:

One inconsistency that has existed in the data for several decay modes was the different manner in which experimenters treated $K_S^0 \to \pi^+\pi^-$ decays. Some chose to treat the pions as

Table 1: Examples of τ -decay modes and their fitted branching fractions.

particle ≥ 0 neutrals ≥ 0 $K_L^0 \nu_{\tau}$	$(84.96 \pm 0.14)\%$
$particle^- \ge 0 \text{ neutrals} \ge 0 K^0 \nu_{\tau}$	$(85.53 \pm 0.14)\%$
$h^-h^-h^+ \geq 0$ neutrals $\nu_{ au}$	$(14.91 \pm 0.14)\%$
$h^-h^-h^+ \geq 0$ neutrals ν_{τ} (ex. $K_S^0 \to \pi^+\pi^-$)	$(14.36 \pm 0.14)\%$
$h^-h^-h^+\pi^0 u_ au$	$(4.44 \pm 0.09)\%$
$h^- h^- h^+ \pi^0 \nu_{ au} \ (ext{ex.} \ K^0)$	$(4.25 \pm 0.09)\%$
$h^-h^-h^+\pi^0 u_ au$ (ex. K^0,ω)	$(2.55 \pm 0.09)\%$

charged prongs from the τ decay, while others rejected them as secondary tracks similar to electrons from photon conversion. To complicate the situation, some experimental papers make no mention as to how these decays were treated, even though different choices can affect some branching fractions by as much as 0.5%, as illustrated in the examples above.

In our definition of τ -decay modes, we treat pions from $K_S^0 \to \pi^+\pi^-$ as charged prongs from the τ decay. To correct branching fraction measurements for different choices, good knowledge of τ branching fractions for decays containing K^0 's is necessary, but until this edition experimental knowledge was meager. In the 1994 edition, the only branching fraction measurement of a τ decay mode containing a K^0 (apart from K^{0} 's used to reconstruct the $K^{*}(892)$) was the measurement, based on 44 detected decays, of B($\tau^- \to K^0 \ h^- \ge 0$ neutrals ν_{τ}) = $(1.3 \pm 0.3)\%$ by the HRS collaboration [7]. For this edition, there are 12 new measurements, based on more than 1800 detected decays, of τ -decay modes containing K^0 's. Consequently, sufficient information now exists, and we have reduced the inconsistency in branching fraction data by moving data to newly defined decay modes consistent with the way $K_S^0 \to \pi^+\pi^-$ decays were treated. Because of time limitations, we did this only for the most precise data.

To make best use of the new data, we have expanded the number of basis modes used in the constrained fit to branching fraction data from 12 in the 1994 edition to 25 in 1996. Consequently, the vast majority of branching fractions listed in the Summary Table are fit results (not averages) which is a significant change from previous editions. The only branching fractions which are not fit results are those which are either upper limits, 3-prong modes where one or more charged particles are identified, or modes containing resonances that are not included in the basis modes.

Selection of the basis modes was determined by several criteria. The basis modes must form an exclusive set whose branching fractions sum exactly to one. All measured branching fractions which contribute to the fit must be expressible in terms of a sum over basis mode branching fractions with accurately known coefficients, and all basis modes (except possibly one) must be constrained by one or more measured branching fractions. It is desirable to include a sufficient number of modes so that the largest number of branching fraction measurements can be included in the constrained fit. Finally,

any modes necessary to satisfy the accuracy requirement must be included. The selected basis modes are listed in Table 2. The coefficients used to define a particular τ branching fraction in terms of the sum over basis mode branching fractions appear in the Listings immediately below each branching fraction header.

Table 2: Basis modes used in the 1994 and 1996 constrained fit to τ branching fraction data.

^{*} Unchanged from RPP94.

In selecting the basis modes, various choices and assumptions were made. For example, we have assumed that branching fractions for the following τ -decay modes are small relative to $0.1\%: \tau^- \to \pi^- \overline{K}^0 \ge 2\pi^0 \nu_{\tau}, \ \tau^- \to \pi^- K^0 \overline{K}^0 \ge 1\pi^0 \nu_{\tau}, \ \tau^- \to \pi^- K^0 \overline{K}^0$ $h^-h^-h^+ \ge 1 \ K^0 \ge 0\pi^0\nu_{\tau}$, and $\tau^- \to h^- \ge 5\pi^0\nu_{\tau}$. Experimental upper limits on branching fractions exist for some of these modes, and comparison of measured inclusive and exclusive branching fractions allow limits to be determined for the others. The modes $\tau^- \to h^- \omega \nu_{\tau}, \ \tau^- \to h^- \omega \pi^0 \nu_{\tau}$, and $\tau^- \to \pi^- \eta \pi^0 \nu_{\tau}$ must be included in the basis set since their combined branching fraction to final states containing photons not from π^0 's is about 0.3%. We have not included in the basis set the mode $\tau^- \to K^*(892)^- \nu_{\tau}$. The branching fraction for this mode is usually determined from the branching fraction for either $\tau^- \to \pi^- \overline{K}^0 \nu_{\tau}$ or $\tau^- \to K^- \pi^0 \nu_{\tau}$ assuming these decays all originate in $\tau^- \to K^*(892)^- \nu_{\tau}$, but these two methods give

 τ

values for $B(\tau^- \to K^*(892)^- \nu_\tau)$ that are inconsistent at the 2.5 σ level irrespective of whether the world average or fit values are used.

The constrained fit to branching fractions assumes all input data are uncorrelated, and data which are very highly correlated are not used in the fit. For the next edition, we plan to enhance the fitting procedure so that data correlations can be properly included. To minimize the effects of older experiments which often have larger systematic errors, we have excluded from the fit 27 older measurements in decay modes which contain at least several of the newer data of much higher precision. As a rule, we exclude those experiments with large errors which together would contribute no more than 5% of the weight in the average.

The precise new measurements have significantly reduced the uncertainties on most fitted branching fractions. Also, some problems in the data noted in the 1994 edition now have reduced significance. Table 3 lists several important hadronic branching fractions that had fit values in both the 1994 and 1996 editions. The reduction of the scale factors for most of these branching fractions illustrates the internal consistency of the new data. Note the significant change in $B(h^-h^-h^+\nu_\tau~({\rm ex.}~K^0))$.

Table 3: Fit branching ratios (%) and scale factors for a sample of τ hadronic decays.

Mode	1994 Fit	Scale	1996 Fit	Scale
$\pi^- u_{ au}$	11.7 ± 0.4	1.3	11.31 ± 0.15	1.1
$K^- u_ au$	0.67 ± 0.23	1.3	0.71 ± 0.05	1.0
$h^-\pi^0 u_ au$	25.7 ± 0.4	1.7	25.76 ± 0.15	1.1
$h^-2\pi^0\nu_{ au}$	9.6 ± 0.4	1.5	9.50 ± 0.14	1.1
$h^-3\pi^0\nu_{ au}$	1.28 ± 0.24	1.7	1.28 ± 0.10	1.0
$h^- h^- h^+ \nu_{\tau} \ (\text{ex. } K^0)$	8.42 ± 0.31	1.3	9.48 ± 0.10	1.1
$h^-h^-h^+ \geq 1$ neutrals ν_{τ}	5.63 ± 0.30	1.2	5.08 ± 0.11	1.2

Other evidence for the improved internal consistency is the decrease in the difference between the fitted and average values for the leptonic branching fractions. In previous editions, the data exhibited a "deficit" in 1-prong exclusive branching fractions for which the fit compensated by systematically increasing all 1-prong fit branching fractions above their average values. Table 4 compares the average and fit values for $B_e \equiv B(\tau^- \to e^- \ \overline{\nu}_e \nu_\tau)$ and $B_\mu \equiv B(\tau^- \to \mu^- \ \overline{\nu}_\mu \nu_\tau)$ for the 1994 and 1996 editions.

Table 4: Fit and average branching fractions for $\tau^- \to e^- \, \overline{\nu}_e \nu_\tau$ and $\tau^- \to \mu^- \, \overline{\nu}_\mu \nu_\tau$.

Branching Fraction (%)		1994	1996		
$\overline{{ m B}_e}$	Fit	18.01 ± 0.18	17.83 ± 0.08

B_{μ}	Fit	17.65 ± 0.24	17.35 ± 0.10		
B_{μ}	Average	17.44 ± 0.23	17.30 ± 0.10		

The charged-prong topological branching fractions changed significantly from their 1994 values. Although only two measurements of charged prong topological branching fractions have been published since the 1994 edition (both of $\mathrm{B}(h^-h^-h^+\geq 0$ neutrals ν_{τ} (ex. $K_S^0 \to \pi^+\pi^-$)), some new measurements of other modes influenced the fitted value of the topological branching fractions. The improved consistency of our treatment of $K_S^0 \to \pi^+\pi^-$ decays also influenced the results. Table 5 compares the average and fit values for $B_1 \equiv B(particle^- \geq 0$ neutrals $\geq 0 \ K_L^0 \ \nu_{\tau}$) and B₃ $\equiv B(h^-h^-h^+ \geq 0 \text{ neutrals } \nu_{\tau})$ for the 1994 and 1996 editions. Although the fit and average values for B₁ and B₃ were very similar in 1994, the new fit values differ significantly from their averages. As the averages of these two modes are formed from older measurements (1992 or earlier), the precise new measurements lead to charged prong topological branching fractions which are significantly different from the older values.

Table 5: Fit and average branching fractions for B_1 and B_3 .

Bran	ching Fraction (%)	1994	1996	
$\overline{\mathrm{B}_{1}}$	Fit	85.49 ± 0.24	84.96 ± 0.14	
B_1	Average	85.46 ± 0.30	85.90 ± 0.30	
B_3	Fit	14.38 ± 0.24	14.91 ± 0.14	
$_{\rm B_3}$	Average	14.32 ± 0.27	14.01 ± 0.29	

Conclusions: The precision of τ branching fraction measurements has increased significantly since the 1994 edition. Measurements of new 1-prong decay modes containing charged and/or neutral kaons have allowed a large expansion in the number of basis modes used in the constrained fit to τ branching fractions. Ambiguities and inconsistencies in the Listings caused by the lack of data on 1-prong modes containing neutral kaons have been significantly reduced. The new level of precision requires experimenters to be especially clear in describing their definition of signal and background in measurements of τ branching fractions. Future measurements of the charged and neutral kaon content in 3-prong τ decays will allow similar improvements in the understanding of those decay modes.

τ^- BRANCHING RATIOS

$\begin{array}{l} \Gamma \text{(particle}^- \geq 0 \text{ neutrals } \geq 0 \textit{K}_{L}^{\textit{U}} \nu_{r} \text{("1-prong"))} / \Gamma_{\text{total}} \\ \Gamma_1 / \Gamma = (\Gamma_3 + \Gamma_5 + \Gamma_9 + \Gamma_{10} + \Gamma_{13} + \Gamma_{15} + \Gamma_{19} + \Gamma_{20} + \Gamma_{23} + \Gamma_{24} + \Gamma_{26} + 0.6569\Gamma_{30} + 0.6569\Gamma_{32} + 0.6569\Gamma_{34} + 0.6569\Gamma_{35} + 0.4316\Gamma_{37} + 0.708\Gamma_{90} + 0.085\Gamma_{97} + 0.08$

The charged particle here can be e, μ , or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below. The measurements used only for the average are marked "avg," whereas "f&a" marks a result used for the fit and the average.

EVTS

 Γ_5/Γ

 $\Gamma(e^-\overline{\nu_e\nu_r})/\Gamma_{\rm total} \qquad \qquad \Gamma_5/\Gamma_{\rm total}$ Data marked "avg" are highly correlated with data appearing elsewhere in the Listings, and are therefore used for the average given below but not in the overall fits. "f&a" marks results used for the fit and the average.

To minimize the effect of experiments with large systematic errors, we exclude experiments which together would contribute 5% of the weight in the average.

au-DECAY PARAMETERS

Neglecting radiative corrections and terms proportional to m_ℓ^2/m_τ^2 , the energy spectrum of the charged decay lepton ℓ in the τ rest frame is given by

$$\frac{d^2\Gamma_{\tau \to \ell \nu \overline{\nu}}}{d\Omega \, dx} \propto x^2$$

$$\times \left\{ 12(1-x) + \rho_{\tau} \left(\frac{32}{3}x - 8 \right) + 24\eta_{\tau} \, \frac{m_{\ell}}{m_{\tau}} \, \frac{(1-x)}{x} \right.$$

$$\left. -P_{\tau} \, \xi_{\tau} \cos \theta \, \left[4(1-x) + \delta_{\tau} \left(\frac{32}{3}x - 8 \right) \right] \right\} . \tag{1}$$

Here $x=2E_\ell/m_\tau$ is the scaled lepton energy, P_τ is the τ polarization, and θ is the angle between the τ spin and the lepton momentum. With unpolarized τ 's or integrating over the full θ range, the spectrum depends only on ρ_τ and η_τ . Measurements of the other two Michel parameters, ξ_τ and δ_τ , require polarized τ 's. The Standard Model predictions for ρ_τ , η_τ , ξ_τ and δ_τ are $\frac{3}{4}$, 0, 1 and $\frac{3}{4}$. Where possible, we give separately the parameters for $\tau^- \to e^- \nu_\tau \overline{\nu}_e$ and $\tau^- \to \mu^- \nu_\tau \overline{\nu}_\mu$, to avoid assumptions about universality. Listings labelled "(e or μ)" contain either the results assuming lepton universality if quoted by the experiments or repeat the results from the "e" or " μ " section.

Hadronic two-body decays $\tau \to \nu_{\tau} h, \ h = \pi, \ \rho, \ a_1, \ \ldots$, can under minimal assumptions be written

$$\frac{1}{\Gamma} \frac{d\Gamma}{dz} = f_h(z) + P_\tau \, \xi_h \, g_h(z) \, , \qquad (2)$$

where the kinematic functions f_h , g_h and the definition of the variable z depend on the spin of the hadron h. For the simple case $h=\pi$, one has $z=E_\pi/E_\tau$, f(z)=1, and g(z)=2z-1. The parameter ξ_h is predicted to be unity and can be identified with twice the negative ν_τ helicity. Again ξ_h is listed, when available, separately for each hadron and averaged over all hadronic decays modes.

Heavy Charged Lepton Searches

Heavy Charged Lepton Searches

Charged Heavy Lepton MASS LIMITS

Sequential Charged Heavy Lepton (L^{\pm}) MASS LIMITS

These experiments assumed that a fourth generation ι^\pm decayed to a fourth generation ι_L (or ι^0) where ι_L was stable. New data show that stable ι_L have $m_{\iota_L} > 42.7$ GeV so that the above assumption is not valid for any mass limit ≤ 42.7 GeV. One can instead assume that ${\it L}^{\pm}$ decays via mixing to ${\it
u}_{\it e}$, ${\it
u}_{\it \mu}$ and/or ${\it
u}_{\it au}$, and in that context the limits below are meaningful. DOCUMENT ID

- 1 The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels $L^-\to e\gamma,\,L^-\to \nu W^-,\,L^-\to eZ;$ and $L^0\to \nu\gamma,\,L^0\to e^-W^+,\,L^-\to \nu Z,$ where the W decays to $\ell\nu_\ell,$ or to jets, and Z decays to $\ell^+\ell^-$ or jets.
- ² RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^-}-m_{L^0}$ was allowed to be quite small, where t^0 denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced m_{L^\pm} range, the mass difference extends to about 4 GeV. 3 STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton (L^+) mass for
- the generalized case in which the corresponding neutral heavy lepton (L^0) in the SU(2) doublet is not of negligible mass.
- doublet is not of magnitude mass. 4 ABE 88 search for L^+ and $L^-\to$ hadrons looking for acoplanar jets. The bound is valid for $m_{\nu}<$ 10 GeV.
- $^{\bf 5}$ ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. ${\sf E_{cm}}^{ee}=$ 52 GeV.
- ⁶ Assumes associated neutrino is approximately massless.
- 7 ADEVA 85 analyze one-isolated-muon data and sensitive to au <10 nanosec. Assume B(lepton) = 0.30. $E_{cm} = 40-47 \text{ GeV}.$
- 8 BARTEL 83 limit is from PETRA $e^{+}\,e^{-}$ experiment with average $E_{\rm cm}=$ 34.2 GeV.

- 9 BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$. 10 BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$. 11 AZIMOV 80 estimated probabilities for M+N type events in $e^+e^- \rightarrow L^+L^-$ deducing semi-hadronic decay multiplicities of L from e^+e^- annihilation data at $E_{cm}=(2/3)m_L$. Obtained above limit comparing these with e^+e^- data (BRANDELIK 80). 12 BARBER 808 looked for $e^+e^- \to L^+L^-$, $L \to \nu_L^+ X$ with MARK-J at DESY-PETRA.
- $^{13}\,\text{ROTHE}$ 69 examines previous data on μ pair production and π and K decays.

NEUTRINOS

(by R.E. Shrock, State Univ. of New York, Stony Brook)

In addition to the ν_e , ν_μ , and ν_τ sections, the Review of Particle Physics includes sections on "Number of Light Neutrino Types," "Heavy Lepton Searches," and "Searches for Massive Neutrinos and Lepton Mixing."

Neutrino experiments are notoriously difficult, owing to the basic property that neutrinos are neutral, weakly interacting particles. Over the years, many experimental claims pertaining to neutrino properties have been refuted by subsequent data. The Review of Particle Physics is an archival compendium which includes references to older papers, even experimental claims which have now been ruled out. It will be clear from the various listings which experiments have later been refuted.

In view of the continuing unsettled nature of data pertaining to various neutrino properties, it is perhaps well to record some of the definite accomplishments in the history of the subject. Neutrinos were first proposed in 1930 by Pauli, to explain the observed continuous electron energy distribution in nuclear beta decay [1]. Tentative evidence for the observation of the electron (anti)neutrino was reported in 1953, and definite evidence in 1956, by Cowan, Reines, and coworkers, using the reaction $\overline{\nu}_e p \to e^+ n$ with $\overline{\nu}_e$'s from reactor fluxes [2]. The separate identity of ν_e and ν_μ was demonstrated experimentally in 1962 by Lederman, Schwartz, Steinberger, and coworkers in a Brookhaven experiment [3]. Neutrinos from the sun were first observed by R. Davis and coworkers via the reaction $\nu_e^{37}\text{Cl} \rightarrow e^{-37}\text{Ar}$, using an underground radiochemical experiment (which began operation in the late 1960's) in the Homestake Gold Mine [4]. Although we tabulate here only experiments with results pertaining to neutrino properties, it should be recalled that neutrino reactions played a crucial role in confirming the now-Standard Model when in 1973 neutral weak currents were first observed by the CERN Gargamelle bubble chamber experiment via the reactions $\nu_{\mu}e \rightarrow \nu_{\mu}e$ and $\nu_{\mu}(\overline{\nu}_{\mu}) + N \rightarrow \nu_{\mu}(\overline{\nu}_{\mu}) \ hadrons [6]$. Neutrino reactions have also provided an important input to the measurement of the weak mixing angle θ_W . The discovery of the τ lepton by Perl et al. at SPEAR in 1975 and the study of its decay implied the existence of the third neutrino, ν_{τ} [7]. The precise measurement of the width of the Z at LEP and SLC has shown that there are only three species of neutrinos (in the usual electroweak doublets) with masses $< m_Z/2$ [8].

The theoretical perspective concerning neutrino masses has changed considerably over the past 20 years. Before that time, a standard view was that there was no theoretical reason for neutrinos to have masses, which was in accord with the striking fact that the upper limits on their masses were much smaller than those of the associated charged leptons. It was also noted that experimental data were consistent with the "laws" of lepton family number and total lepton number conservation. (Some early discussions of of neutrino oscillations and lepton mixing are given in Refs. 9 and 10). In the literature through the

1970's one often finds statements asserting that in the standard $\mathrm{SU}(2)\,\times\,\mathrm{U}(1)$ electroweak theory (without electroweak-singlet neutrinos) the known neutrinos (in electroweak-doublets) are massless. This is true if one pretends that the Standard Model is applicable to arbitrarily high energies and requires the exact absence of any nonrenormalizable, higher-dimension operators in this theory. However, a more modern view is that the Standard Model is an effective field theory, which is a good description of nature only up to some energy scale where new physics occurs. Clearly a strict upper bound on this scale is given by the Planck mass, $\overline{M}_{Pl} \equiv \sqrt{\hbar c/(8\pi G_N)} = 2.4 \times 10^{18} \text{ GeV}$, since quantum gravity is not included in the Standard Model. However, there are strong arguments that new physics beyond the Standard Model actually occurs at a much lower scale, of order a TeV. This new physics may be able to be included in a generalization of the Standard Model which remains perturbative, as in supersymmetric extensions, or may be nonperturbative, as in dynamical electroweak symmetry breaking schemes. It has been appreciated that renormalizability and, in particular, the great success of the Standard Model with its exclusion of any higher-dimension nonrenormalizable operators, may well be due only to the fact that the electroweak scale $\boldsymbol{v}_{\scriptscriptstyle EW}$ is considerably smaller than the scale of new physics. A summary of this modern view is given, e.g., in Ref. 11.

Once one includes higher-dimension operators in the Lagrangian, nonzero neutrino masses can easily occur. The sizes of these masses reflect the scale(s) of the new physics. For example, given only the known left-handed neutrino fields of the Standard Model, there would be a gauge-invariant dimension-5 operator

$$\mathcal{O} = \frac{1}{M_X} \sum_{a,b} h_{a,b} (\epsilon_{ik} \epsilon_{jm} + \epsilon_{im} \epsilon_{jk}) \left[\mathcal{L}_{La}^{Ti} C \mathcal{L}_{Lb}^{j} \right] \phi^{k} \phi^{m} + h.c. (1)$$

where $\mathcal{L}_{La}=(\nu_{\ell_a},\ell_a)_L^T$ is the left-handed, $I=1/2,\ Y=-1$ lepton doublet with generation index a ($a=1,\ 2,\ {\rm or}\ 3$), where $\ell_a=e,\mu,\tau$, for a=1,2,3, and M_X denotes a generic mass scale characterizing the origin of this term. This operator involves a symmetric, I=1 combination of the two I=1/2 lepton doublets, contracted with an I=1 combination of the two Higgs doublets. The term arising from the vacuum expectation values (vev's) of the Higgs doublets yields a (left-handed) Majorana neutrino mass term (symmetric in generation indices). If $M_X>>v_{EW}$, where $v_{EW}=2^{-1/4}G_F^{-1/2}=246$ GeV is the electroweak symmetry breaking scale, this would explain the smallness of the resultant neutrino masses.

Because of the hierarchy problem plaguing the Higgs sector of the Standard Model, many physicists have concluded that either this sector is stabilized against large radiative corrections by supersymmetry, or the electroweak symmetry breaking originates not from the vacuum expectation value of a pointlike Higgs field, but instead dynamically, from the condensation of bilinear products of fermion fields without any fundamental Higgs field. In supersymmetric extensions of the Standard Model, one again finds dimension-5 operators analogous to

Neutrinos

Eq. (1). In approaches based on dynamical electroweak symmetry breaking, one can also get neutrino mass terms arising from higher-dimension multifermion operators.

In contrast to the higher-dimension operator (1), which involves only the known neutrinos, together with the hypothetical Higgs field of the Standard Model (or its supersymmetric extensions), another mechanism makes use only of renormalizable, dimension-4 operators, but requires the existence of electroweak-singlet neutrino fields. As will be discussed below, this mechanism produces light neutrino masses of order $m_{\nu} \sim M_D^2/M_R$, where M_D denotes a generic Dirac neutrino mass and M_R denotes a generic electroweak-singlet Majorana neutrino mass. Since the mass scale of the electroweak singlet neutrino mass term is naturally $>> v_{EW}$, this again yields, albeit for a different reason, very small m_{ν} [12].

In turn, a natural concomitant of (nondegenerate) neutrino masses is lepton mixing, which is thus also a general expectation. The lepton-mixing angles are functions of ratios of elements of neutrino-matrix elements and of charged lepton mass matrix elements, and even though left-handed neutrino masses are small, some of these ratios could, in principle, be $\mathcal{O}(1)$, which raises the issue of why such effects have not been seen. This question was answered as follows: a set of conditions for natural suppression of observable lepton flavor violation were formulated, and it was shown that the Standard Model (generalized to include nonzero m_{ν}) satisfies these [13]. This explains why the "law" of lepton family number conservation is obeyed to such high accuracy.

After these theoretical points, let us return to a description of the quantities upon which various experiments put limits. As an aid to understanding the limits on neutrino masses and lepton mixing, we recall that, in contrast to other particles in this Review, the neutrinos ν_e , ν_μ , and ν_τ are defined as weak eigenstates (the weak $I_3 = 1/2$ components of the $SU(2)_L$ lepton doublets) which couple with unit strength to e, μ , and τ , respectively. These neutrino weak eigenstates are not, in general, states of definite mass. If one assumes that neutrinos are massless, and hence degenerate, then it is possible to define the weak eigenstates to be simultaneously mass eigenstates. However, in the general case of possibly massive (nondegenerate) neutrinos, the weak eigenstates have no well-defined masses, but instead are linear combinations of mass eigenstates. Let us denote the charged leptons as the set $\{\ell_a\}$, $a=1,\ldots,n$, where $n\geq 3$, with $\ell_1 = e$, $\ell_2 = \mu$, and $\ell_3 = \tau$. From the LEP measurement of the Z width (see section on "Number of Light Neutrinos"), one knows that there are only three neutrinos which couple to the Z in the usual way and have masses $m_{\nu} < m_{Z}/2$. Of course, this measurement does not preclude the existence of electroweak-singlet neutrinos. The left-handed components of the weak eigenstates of the neutrinos, $(\nu_{\ell_a})_L$ can be expressed in terms of mass eigenstates by the transformation

$$(\nu_{\ell_a})_L = \sum_j U_{aj}(\nu_j)_L \tag{2}$$

where the $\{\nu_j\}$ denote these mass eigenstates. The mass eigenstates are, in general, linear combinations of the known I=1/2, $I_3=1/2$ neutrinos from electroweak doublets, and, in addition, possible electroweak-singlet neutrinos (sometimes called "sterile" neutrinos). The ordering of the mass eigenbasis can be defined so that U is as nearly diagonal as possible, *i.e.* (with no sum on j) $|U_{jj}| \geq |U_{jk}|$, $k \neq j$. Of course, this does not imply that $m(\nu_j) > m(\nu_k)$ for j > k.

Thus, as was noted in Ref. 14, decays such as $^3{\rm H}$ \rightarrow ³He $e^- \overline{\nu}_e$ and $\pi^+ \to \mu^+ \nu_\mu$, which have been used to set the best bounds on the respective neutrino masses, really consist of sums of the separate decay modes ${}^{3}\text{H} \rightarrow {}^{3}\text{He} \ e^{-} \ \overline{\nu}_{i}$ and $\pi^+ \to \mu^+ \nu_k$, where the ν_i and ν_k are mass eigenstates, and the indices j and k range over all of the values allowed by phase space in these respective decays. The coupling strengths for the jth mode in ${}^{3}\mathrm{H}\beta$ decay and the kth mode in π_{u2}^{+} decay are given, respectively, by $|U_{1j}|^2$ and $|U_{2k}|^2$. In general, these modes are incoherent, although in the limit in which the ν_i all become degenerate they would become coherent. There are, in addition certain kinematic factors depending on the m_{ν_i} which enter in determining the branching ratio for a given decay mode. Assuming that the off-diagonal elements of the lepton mixing matrix U are small relative to the diagonal elements, the dominantly coupled decays are the ones with coupling strength $|U_{ai}|^2$, a=j, i.e., ${}^3\mathrm{H} \rightarrow {}^3\mathrm{He} \ e^- \ \overline{\nu}_1$ and $\pi^+ \rightarrow \mu^+ \nu_2$.

Hence, it follows that the neutrino mass limits quoted in the literature for " m_{ν_e} ," " $m_{\nu_{\mu}}$," and " $m_{\nu_{\tau}}$ " should really be interpreted as limits on the corresponding mass eigenstates [14,15]. Specifically, a bound on " m_{ν_e} " from a study of tritium β decay, for example, really constitutes a weighted limit on each of the mass eigenstates ν_i in the weak eigenstate ν_e which are kinematically allowed to occur in tritium decay and which are coupled with strength $|U_{1j}|^2$ sufficiently large to make a significant contribution to the observed spectrum. It is thus certainly a limit on ν_1 , since this is, by the definition, of the order of the mass eigenbasis, the dominantly coupled neutrino. If lepton mixing is hierarchical, as quark mixing is known to be, i.e., if $|U_{ij}|^2 \gg |U_{ik}|^2$, $j \neq k$, then ν_1 is the only mass eigenstate significantly constrained by a bound on " m_{ν_e} ." Furthermore, strictly speaking, a neutrino mass limit cannot be stated in isolation; it always contains some implicit dependence on the relevant lepton-mixing angles. This dependence is fortunately relatively unimportant for the dominantly coupled decay modes, i.e., $e \overline{\nu}_1$, $\mu \overline{\nu}_2$, and $\tau \overline{\nu}_3$ and hence the mass limits on " m_{ν_e} ," " $m_{\nu_{\mu}}$," and " $m_{\nu_{\tau}}$ " can be reinterpreted as being limits on $m_{\nu_{i}}$, j = 1, 2, and 3, respectively.

There are three general types of (Lorentz-invariant) neutrino mass terms: Dirac masses of the form $m_D \, \overline{\nu}_L \, \chi_R + h.c.$, left-handed Majorana masses of the form $m_L \, \overline{\nu}_L \, \nu_R^c + h.c. = m_L^* \, \nu_L^T \, C \nu_L + h.c.$ and right-handed Majorana masses of the form $m_R \, \overline{\chi}_L^c \, \chi_R + h.c. = m_R \, \chi_R^T \, C \, \chi_R + h.c.$, where C is the Dirac charge conjugation matrix. Clearly, Dirac and right-handed Majorana mass terms require the existence of electroweak-singlet neutrinos. Our notation χ_R follows the usual practice of calling

Lepton Particle Listings Neutrinos

these "right-handed neutrino singlets", although since they are singlets, it is a convention whether one writes them as χ_R or $\chi'_L = (\chi_R)^c$. It is not known whether such electroweak-singlet neutrinos actually exist. Dirac mass terms conserve total lepton number L_{tot} , while Majorana mass terms violate L_{tot} . In the standard electroweak theory, extended to include massive neutrinos, (i) a Dirac mass term transforms as a weak I = 1/2operator, and is coupled to the I = 1/2 Higgs to make an SU(2) × U(1) singlet operator; (ii) a Majorana mass term involving the I = 1/2 left-handed neutrinos transforms as I = 1 and must be coupled to an operator with I = 1 (and Y = 2) to make a gauge-invariant singlet; (iii) a Majorana mass term involving the $SU(2) \times U(1)$ singlet neutral leptons, conventionally considered to be right-handed, is a singlet; it could be present as a bare mass term or couple to some other singlet operator. Note that in the minimal supersymmetric Standard Model (MSSM), which has two Higgs doublets, of hypercharge Y = 1 and Y = -1, the Dirac neutrino mass term arises from the cubic chiral superfield terms $\epsilon_{ij} \sum_{a,b} \hat{L}_a^i \hat{\chi}_b^c \hat{H}_u^j$ (all chiral superfields are taken as left-handed), where \hat{H}_u is the same Higgs that gives mass to the Q=2/3 quarks. The Dirac neutrino mass terms are thus proportional to $\sin \beta$, where $\tan \beta = v_u/v_d$ is the ratio of the vacuum expectation values of the two Higgs in the MSSM.

In general, in the Standard Model, in addition to the three known left-handed I=1/2 lepton doublets, there could be some number n_s of electroweak-singlet neutrinos. In a compact notation, one can then denote ν_L as the 3-component vector of left-handed I=1/2 neutrinos and χ_R to be the n_s -dimensional vector of electroweak-singlet singlets, taken to be right-handed. The general neutrino mass term in the Lagrangian is then given by

$$-\mathcal{L}_{m} = \frac{1}{2} (\overline{\nu}_{L}, \overline{\chi}_{L}^{c}) \begin{pmatrix} M_{L} & M_{D} \\ M_{D}^{T} & M_{R} \end{pmatrix} \begin{pmatrix} \nu_{R}^{c} \\ \chi_{R} \end{pmatrix} + h.c.$$
 (3)

where M_L is the 3×3 left-handed Majorana-mass matrix, M_R is a $n_s \times n_s$ right-handed Majorana-mass matrix, and ${\cal M}_D$ is the 3-row by n_s -column Dirac-mass matrix. In general, all of these mass matrices are complex. The anticommutativity of fermion fields and the property that $C\gamma_{\mu}C^{-1} = -\gamma_{\mu}^{T}$ together imply that the Majorana mass matrices are symmetric: $M_L = M_L^{\ T}, M_R = M_R^{\ T}$. The diagonalization of the full $(3 + n_s) \times (3 + n_s)$ mass matrix in Eq. (2) yields $3 + n_s$ mass eigenstates, which are, in general, of Majorana type. Since Majorana mass terms violate total lepton number, one sees from a general viewpoint that one does not expect conservation of total lepton number. In particular, the dimension-5 operators discussed above give rise to left-handed Majorana neutrino mass terms and violate total lepton number. Diracneutrinos can be constructed from two Majorana-neutrino mass eigenstates whose masses are equal in magnitude [16]. For this reason, Dirac neutrino masses may be considered to be a special (degenerate) case of Majorana neutrino masses, and the latter may be regarded as the generic case. From the transformation which diagonalizes the neutrino mass matrix, together with the transformation which diagonalizes the charged lepton mass matrix (where, of course, only Dirac masses are allowed by electric-charge conservation), one constructs the lepton-mixing matrix U. In general, since U is not the identity, neutrino masses naturally give rise to lepton family number violation.

In supersymmetric extensions of the Standard Model, the neutrinos could, a priori, mix with the neutralinos (higgsinos and neutral gauginos). However, the usual R parity which is invoked to forbid unacceptably rapid proton decay also prevents such mixing between neutrinos and neutralinos.

In addition to mass and lifetime limits, this Review includes limits on various other possible properties, including electric charge, the CPT-violating difference $m_{\nu_1}-m_{\overline{\nu}_1}$, and a magnetic dipole moment. These are of interest because a massless purely chiral Dirac neutrino cannot have a magnetic (or electric) dipole moment. In the standard electroweak theory, extended to allow for Dirac neutrino masses, the neutrino magnetic dipole moment is nonzero and given [13,17], as

$$\mu_{\nu_j} = \frac{3eG_F m_{\nu_j}}{8\pi^2 \sqrt{2}} = 3.2 \times 10^{-19} (m_{\nu_j}/1 \text{ eV}) \mu_B \tag{4}$$

where G_F is the Fermi constant and $\mu_B = e/2m_e$ is the Bohr magneton. The neutrino electric dipole moment violates both time-reversal invariance and parity; although it is nonzero in general, it is quite small (see, e.g. Ref. 18). Again, however, we note that Dirac neutrinos should be regarded as a special case; the generic case is Majorana neutrinos. Because of the properties

$$C\Gamma C^{-1} = -\Gamma$$
, $\Gamma = \sigma_{\alpha\beta}$, $\sigma_{\alpha\beta}\gamma_5$ (5)

it follows that the operator products which define the magnetic and electric dipole moments are of the respective forms

$$(\overline{\nu}_i \sigma_{\alpha\beta} \nu_i - \overline{\nu}_i \sigma_{\alpha\beta} \nu_i) F^{\alpha\beta} \tag{6}$$

and

$$(\overline{\nu}_i \sigma_{\alpha\beta} \gamma_5 \nu_j - \overline{\nu}_j \sigma_{\alpha\beta} \gamma_5 \nu_i) F^{\alpha\beta} \tag{7}$$

(where $F^{\alpha\beta}$ is the electromagnetic field strength tensor). Hence, if ν_i is a Majorana neutrino (mass eigenstate), its magnetic and electric dipole elements vanish identically. Although only the diagonal magnetic and electric dipole moments are static properties of a given neutrino mass eigenstate, transition magnetic and electric dipole moments may exist, in general, for both Dirac and Majorana neutrinos.

Occasionally, one also finds references to the "neutrino charge radius" in the literature. This is defined via the Taylor series expansion of the generalized vector Dirac form factor multiplying γ_{μ} in the electromagnetic current matrix element: $F_1^V(q^2) = F_1^V(0) + q^2 \, dF_1^V/dq^2|_{q^2=0} + \mathcal{O}[(q^2)^2]$, where q denotes the 4-momentum of the photon [see, e.g. Ref. 13 Eq. (2.20)]. The electric charge is $Q = F^V(0) = 0$ for a neutrino, and the charge radius is given by $\langle r^2 \rangle = (1/6)(F_1^V)'(0)$. However,

Neutrinos

since this is multiplied by q^2 in the Taylor series expansion, it never occurs for a real photon, where $q^2=0$, and hence is not an S-matrix element, *i.e.*, not a physical quantity. In a gauge theory, this is manifested in the fact that the charge radius is gauge-dependent.

If one considers the possibility of nonzero masses for neutrinos, for consistency one must then also consider the leptonic mixing which would in general occur concomitantly. Accordingly, this Review devotes a section to correlated bounds on neutrino masses and lepton mixing angles. These can be divided into two types. First, there are those due to decays involving neutrinos in the final state, which must be recognized to have the possible multimode structure pointed out above. In the two most sensitive cases suggested as tests for neutrino masses and mixing, one obtains a limit on m_{ν_i} and $|U_{aj}|^2$ individually for each j. The peak-search test proposed in Ref. 14 was applied to existing data in that paper and a subsequent one [15]; it was applied in new experiments on 2-body leptonic decays of K^+ and π^+ by several groups at SIN (PSI), KEK, and TRIUMF. The results are catalogued in corresponding subsections on limits on $|U_{1j}|^2$ and $|U_{2j}|^2$. The kink-search test was also applied by a number of groups. The experimental situation, which was controversial for many years, has recently been clarified (see below).

Second, there are those due to processes involving the propagation and subsequent interaction of neutrinos. The latter are often called neutrino-oscillation limits, although this term is strictly correct only if the differences in neutrino masses are sufficiently small relative to their momenta that the propagation is effectively coherent in a quantum mechanical sense; otherwise, the individual ν_j from a given decay such as $\pi_{\mu 2}$ or $K_{\mu 2}$ propagate in a measurably incoherent manner, and there is no oscillation. Experimentalists usually present their results in terms of a simplifying model in which mixing is assumed to occur only between two neutrino species. The relevant transformation equation becomes

$$\begin{pmatrix} \nu_{\ell_a} \\ \nu_{\ell_b} \end{pmatrix} = \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} \nu_i \\ \nu_j \end{pmatrix} \tag{8}$$

where ν_{ℓ_a} are the neutrino weak eigenstates, with $\nu_{\ell_1} = \nu_e$, etc., and ν_i are neutrino mass eigenstates. A given decay, such as $\pi^+ \to \mu^+ \nu_\mu$, produces, at time t=0, the neutrino mass eigenstates which are contained in the weak eigenstate ν_μ and are kinematically allowed to occur as decay products. Each mass eigenstate picks up a phase as it propagates, so that at time t, the jth eigenstate, as a quantum-mechanical state, has acquired a phase $\exp(-iE_jt)$, where E_j denotes its energy. Strictly speaking, E_j must be considered to be complex, since a massive neutrino will, in general, decay. Indeed such neutrino decays have been searched for in various experiments (see Listings). In the present discussion, we shall neglect this; for the ranges of neutrino masses of relevance to terrestrial neutrino oscillation experiments, such decays should have a

negligible effect on the observed oscillations. (Indeed, the observation of neutrinos at about the expected rate from the 1987 supernova places significant lower bounds on neutrino lifetimes.) According to basic quantum mechanics, one cannot measure the energies E_j or momenta $p_j = \sqrt{E_j^2 - m_{\nu_j^2}}$ to arbitrary precision; rather, $\Delta E_j \Delta t_j \gtrsim \hbar/2$ and $\Delta(p_x)_j \Delta x_j \gtrsim \hbar/2$. Correspondingly, the neutrinos actually propagate as wavepackets. As noted above, if the mass differences $|m_{\nu_i} - m_{\nu_k}|$ are sufficiently small relative to the energies $E_i \simeq E_k$, then the resultant velocities are sufficiently close that these wavepackets will continue to maintain a high degree of overlap during the relevant time that they propagate in the experiment, and hence the individual mass eigenstates will remain effectively coherent in the quantum mechanical sense. Their propagation may then be characterized by a single momentum p. Now assume that, after having propagated for a time t (and hence, for $1-v/c \ll 1$, a distance L = ct), the neutrino(s) scatter via a charged current weak interaction. This again projects out the weak interaction eigenstates. In particular, because of the different phases which the mass eigenstates pick up during the propagation, a neutrino which is emitted as ν_{ℓ_a} has a nonzero probability to produce

$$P = |\langle \nu_{\ell_b}(t) | \nu_{\ell_a}(0) \rangle|^2 = \sin^2(2\theta) \sin^2\left(\frac{\Delta m^2 L}{4E}\right)$$
 (9)

where

$$\Delta m^2 = m_{\nu_i}^2 - m_{\nu_i}^2 \tag{10}$$

Numerically, $\Delta m^2 L/(4E) = (1.266932...)\Delta m^2 L/E$, where Δm^2 is measured in eV^2 , L in m, and E in MeV (or L in km, E in GeV). Thus, neutrino oscillation experiments cannot measure individual neutrino masses, but only differences of masses squared, and indeed these are generally weighted in a more complicated way by lepton mixing matrix coefficients for the general case where there is mixing among more than just two species. Experimental results are presented as allowed regions on a plot, the axes of which are $|\Delta m^2|$ and $\sin^2 2\theta$. These are often summarized in terms of the upper limit on Δm^2 (the absolute value is usually suppressed in the notation) for maximal mixing, $\sin^2 2\theta = 1$, and the upper limit on $\sin^2 2\theta$ for "large" Δm^2 , i.e., sufficiently large $|\Delta m^2|$ that the detector averages over many cycles of oscillation (or there ceases to be any coherence). A more complete discussion is given in the "Note on Neutrino Oscillation Experiments" just before the tables reporting such results.

An important type of experiment is the search for neutrinoless double- β decay, which tests for total lepton number violation such as would result for Majorana-neutrino masses. This process takes place when a nucleus with Z protons and A=ZN nucleons decays according to $(Z,A) \to (Z+2,A)e^-e^-$, violating total lepton number by two units. In the case of neutrinos with masses which are sufficiently light, an upper limit

on neutrinoless double- β decay yields a correlated upper limit on the quantity

$$\overline{m} = \left| \sum_{j} U_{1j}^2 m_{\nu_j} \right| . \tag{11}$$

Cancellations may occur in the sum, since U_{1j} is, in general, complex. The situation is explored further in the minireview by Petr Vogel which prefaces the double- β decay sections. See Ref. 19 for some recent reviews of searches for neutrinoless double- β decay.

A brief summary of the current experimental situation follows (see previous editions for discussions of various positive claims for neutrino masses and mixing, and their refutations).

- 1. There is no evidence at present from direct searches for nonzero neutrino masses. These include the endpoint of the Kurie plot in nuclear beta decay for $m(\nu_e)$, $\pi^+ \to \mu^+ \nu_\mu$ for $m(\nu_\mu)$, and certain τ decays for $m(\nu_\tau)$ (where, as discussed above, the limits actually apply to the respective mass eigenstates ν_1 , ν_2 , and ν_3 in these three weak eigenstates).
- 2. There are no indications of any positive neutrino masses from any of the peak search experiments in π or K decay, or from any experiments on neutrino decays.
- 3. There are no indications of any positive neutrino masses from nuclear beta decay spectra. The 7-year controversy over the claim by Simpson, Hime, and others of a 17 keV neutrino is finally over, with retractions by these authors of their original claims after very strong refutations by a number of high-sensitivity experiments.
- 4. A number of positive claims for neutrino oscillations in reactor and accelerator neutrino experiments have either been refuted or retracted, or both (see previous editions for details). However, in one analysis, the LSND (Liquid Scintillator Neutrino Detector) group at Los Alamos has reported evidence for the neutrino oscillation $\overline{\nu}_{\mu} \rightarrow \overline{\nu}_{e}$ [20]. A dissenting analysis of the data by a member of the collaboration reports no evidence for neutrino oscillations [21]. More recently, the LSND group has increased its data sample and strengthened its evidence for neutrino oscillations [22].
- 5. There is no indication of Majorana neutrino masses from searches for neutrinoless double- β decay.
- 6. Several experiments have reported evidence for atmospheric neutrino oscillations. Other experiments report results consistent with no such oscillations. This situation is unsettled at present.
- 7. It is generally acknowledged that the strongest indirect evidence for neutrino masses and mixing is the observed deficit in the solar neutrino flux. The current situation is reviewed by K. Nakamura as a preface to the Solar Neutrino Listings.

For some recent reviews on neutrino physics and further references to the original literature, see Refs. 23–28.

 $J = \frac{1}{2}$

Not in general a mass eigenstate. See note on neutrino properties above.

These limits apply to ν_1 , the primary mass eigenstate in ν_e . They would also apply to any other ν_j which mixes strongly in ν_e and has sufficiently small mass that it can occur in the respective decay. The neutrino mass may be of a Dirac or Majorana type; the former conserves total lepton number while the latter violates it. Either would violate lepton family number, since nothing forces the neutrino mass eigenstates to coincide with the neutrino interaction eigenstates. For limits on a Majorana ν_e mass, see the section on "Searches for Massive Neutrinos and Lepton Mixing," part (C), entitled "Searches for Neutrinoless Double- β Decay."

The square of the neutrino mass $m_{\nu_e}^2$ is measured in tritium beta decay experiments by fitting the shape of the beta spectrum near the endpoint; results are given in one of the tables in this section. In many experiments, it has been found to be significantly negative. In the 1994 edition of this Review, it was noted that the combined probability of a positive result was 3.5%. The problem has been exacerbated by the precise and careful experiments reported in two new papers (BELESEV 95 and STOEFFL 95). Both groups conclude that unknown effects cause the accumulation of events in the electron spectrum near its end point. If the fitting hypothesis does not account for this, unphysical values for $m_{\nu_e}^2$ are obtained. BELESEV 95 obtain their value for $m_{\nu_e}^2$ and limit for m_{ν_e} (4.35 eV at 95% CL) under the assumption that a certain narrow region is free of both high-energy and low-energy anomalies. Including the endpoint accumulation (they find no low-energy anomaly), STOEFFL 95 find a value for $m_{\nu_e}^2$ which is more than 5 standard deviations negative, and report a Bayesian limit of 7 eV for m_{ν_e} which is obtained by setting $m_{\nu_e}^2 = 0$. Given the status of the tritium results, we find no clear way to set a meaningful limit on m_{ν_e} . On the other hand, a mass as large as $10-15~\mathrm{eV}$ would probably cause detectable spectrum distortions near the endpoint.

The spread of arrival times of the neutrinos from SN 1987A, coupled with the measured neutrino energies, should provide a simple time-of-flight limit on m_{ν_e} . This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The LOREDO 89 limit (23 eV) is among the most conservative and involves few assumptions; as such, it is probably a safe limit. We list this limit below as

"used," but conclude that a limit about half this size is justified by the tritium decay experiments.

ν_e MASS

Most of the data from which these limits are derived are from β^- decay experiments in which a $\overline{\nu}_e$ is produced, so that they really apply to $m_{\overline{\nu}_1}.$ Assuming CPT invariance, a limit on $m_{\overline{\nu}_1}$ is the same as a limit on $m_{\nu_1}.$ Results from studies of electron capture transitions, given below " $m_{\nu_1}-m_{\overline{\nu}_1}$ ", give limits on m_{ν_1} itself. OUR EVALUATION of the present status of the tritium decay experiments is discussed in the above minireview.

- 1 BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous triftium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields $m_{\nu'}^2=-4.1\pm10.9~{\rm eV}^2$, leading to this Bayesian limit.
- ² CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of m_{ν}^2 is given.
- ³ HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m_{\nu}^2=221\pm4244~{\rm eV}^2$ from the two runs listed below.
- the two runs listed below. 4 STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the m_{ν}^2 errors given below but with m_{ν}^2 set equal to 0. The anomalous endpoint accumulation leads to a value of m_{ν}^2 which is negative by more than 5 standard deviations.
- 5 The YASUMI 94 (KEK) limit results from their measurement $m_{\nu}{=}110 {+}\, ^{+350}_{-110}$ eV.
- ⁶ WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- tritium frozen onto an aluminum substrate. 7 HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m_{\nu}^2 = -24 \pm 48 \pm 61$ (1 σ errors), in eV², using the PDG prescription for conversion to a limit in m_{ν} .
- ⁸ KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the m_{ν}^2 limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.
- 9 ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν} lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature. 10 See also comment in BORIS 87a and erratum in BORIS 88.

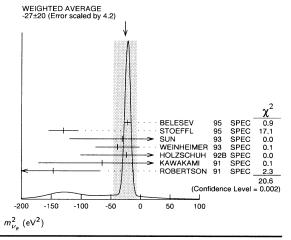

ν_e MASS SQUARED

The tritium experiments actually measure mass squared. A combined limit on mass must therefore be obtained from the weighted average of the results shown here. The recent results are in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88, erratum)] that m_{ν_1} lies between 17 and 40 eV. The BORIS 87 result is excluded because of the controversy over the possibly large unreported systematic errors; see BERGKVIST 858, BERGKVIST 86, SIMPSON 84, and REDONDO 89. However, the average for the new experiments given below implies only a 3.5% probability that m^2 is positive. See HOLZSCHUH 92 for a review of the recent direct m_{ν_1} measurements.

- 11 BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7-15 eV below the endpoint.

 12 STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup
- of events at the endpoint leads to the negative value for m_{ν}^2 . The authors acknowledge that "the negative value for the best fit of m_{ν}^2 has no physical meaning" and discuss possible explanations for this effect.
- 13 SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.
- 14 WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- 15 HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.
- 16 KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.
- 17 ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν} lies between 17 and 40 eV. However, the probability of a positive m_{ν}^2 is only 3% if statistical and systematic error are combined in quadrature.
- $^{18}\,\mathrm{HIDDEMANN}$ 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.

$m_{\nu_1}-m_{\overline{\nu}_1}$

These are measurement of m_{ν_1} (in contrast to $m_{\overline{\nu}_1}$, given above). The masses can be different for a Dirac neutrino in the absense of *CPT* invariance. ance. The test is not very strong.

²⁶ REINES 74 looked for ν_e of nonzero mass decaying to a neutral of lesser mass + γ . Used liquid scintillator detector near fission reactor. Finds lab lifetime $6. \times 10^7$ s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit 6. x 10^7 s REINES 74 assumed that the full $\overline{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV - 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of their lower limit is an over-estimate of the other lower limit is an over-estimate of their lower limit is an over-estimate of the other lower limit is an over-esti lab lifetime (P. Vogel, private communication, 1984).

27 BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained. 28 Nonobservation of γ 's in coincidence with ν 's from SN 1987A.

 29 KRAKAUER 91 quotes the limit $\tau/m_{\nu_1}~>$ (0.3a^2 +~9.8a+15.9) s/eV, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_{\gamma}/d{\rm cos}\theta=$ $(1/2)(1 + a\cos\theta)$ a = 0 for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for

30 CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino. 31 Model-dependent theoretical analysis of SN 1987A neutrinos.

32 OBERAUER 87 bounds are from comparison of observed and expected rate of reactor

33 RAFFELT 85 limit is from solar x- and γ -ray fluxes.

 34 STECKER 80 limit based on UV background; result given is $au > 4 imes 10^{22}\,\mathrm{s}$ at $m_{
u} = 20$

$|(v-c)/c| (v \equiv \nu_1 \text{ VELOCITY})$

Expected to be zero for massless neutrino, but tests also whether photons and neutrinos have the same limiting velocity in vacuum.

 35 STODOLSKY 88 result based on $<\!10$ hr between $\overline{\nu}_e$ detection in IMB and KAMI detectors and beginning of light signal. Inclusion of the problematic 5 neutrino events from FREJ (four hours later) does not change the result.

ν_1 MAGNETIC MOMENT

Must vanish for Majorana neutrino or purely chiral massless Dirac neutrino. The value of the magnetic moment for the standard $SU(2) \times U(1)$ electroweak theory extended to include massive neutrinos (see FUJIKAWA 80) troweak theory extended to include massive heutrinos (see FUJIKAVA 80) is $\mu_{\nu}=3eG_{F}m_{\nu}/(8\pi^{2}\sqrt{2})=(3.20\times10^{-19})m_{\nu}\mu_{B}$ where m_{ν} is in eV and $\mu_{B}=e\hbar/2m_{e}$ is the Bohr magneton. Given the upper bound $m_{\nu_{1}}<7.3$ eV, it follows that for the extended standard electroweak theory, $\mu(\nu_{1})<2.3\times10^{-18}~\mu_{B}$. Current experiments are not yet challenging this limit. There is considerable controversy over the validity of many of the claimed upper limits on the magnetic moment from the astrophysical data. For example, VOLOSHIN 90 states that "in connection with the astrophysical limits on μ_{ν} , ... there is by now a general consensus that contrary to the initial claims (BARBIERI 88, LATTIMER 88, GOLD-MAN 88, NOTZOLD 88), essentially no better than quoted limits (from previous constraints) can be derived from detection of the neutrino flux from the supernova SN1987A." See VOLOSHIN 88 and VOLOSHIN 88c.

NONSTANDARD CONTRIBUTIONS TO NEUTRINO SCATTERING

We report limits on the so-called neutrino charge radius squared in this section. This quantity is not an observable, physical quantity and this is reflected in the fact that it is gauge dependent (see LEE 77c). It is not necessarily positive. A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

 $^{^{47}}$ VIDYAKIN 92 limit is from a $e\overline{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\!\theta_W = 0.23$ as input. 48 GRIFOLS 89B sets a limit of $\left\langle r^2\right\rangle < 0.2\times 10^{-32}\,\mathrm{cm}^2$ for right-handed neutrinos.

³⁷ GOYAL 95 assume that helicity flip via μ_{ν} would result in faster cooling and hence shorter burst from SN1987A. Limit is based on the assumed presence of a pion condensate or

burst from \$1987A. Limit is based on the assumed presence of a pion condensate or quark core in the remanant.

38 VIDYAKIN 92 limit is from a $e\overline{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.

 ^{1/10.} The limit uses Sin - W = 0.23 as input.
 39 KRAKAUER 90 experiment fully reported in ALLEN 93.
 40 RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives < 1.4 × 10⁻¹². Limit at 95%CL obtained from δM_C.

 $^{^{41}}$ Significant dependence on details of stellar models. 42 A limit of 10^{-13} is obtained with even more model-dependence.

 $^{^{43}}$ These papers have assumed that the right-handed neutrino is inert; see BARBIERI 88B.

⁴⁴ FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu < 10^{-16} \left[10^{-9} \, G/B_0\right]$ where B_0 is the present-day intergalactic field strength.

⁴⁵ Some dependence on details of stellar models.

⁴⁶ We obtain above limit from SUTHERLAND 76 using their limit f < 1/3.

 $J = \frac{1}{2}$

Not in general a mass eigenstate. See note on neutrinos in the ν_a

u_{μ} MASS

Applies to ν_2 , the primary mass eigenstate in ν_μ . Would also apply to any other ν_j which mixes strongly in ν_μ and has sufficiently small mass that it can occur in the respective decays. (This would be nontrivial only for \geq 3, given the $u_{
m e}$ mass limit above.) Results based upon an obselete pion mass are no longer shown; they were in any cass less restrive than ASSAMAGAN 96.

- 1 ASSAMAGAN 96 measurement of ho_μ from $\pi^+
 ightarrow \ \mu^+
 u_\mu$ at rest combined with JECK-ELMANN 94 Solution B pion mass yields $m_{\nu}^2 = -0.016 \pm 0.023$ with corresponding
- bayesian limit listed above. If Solution A is used, $m_2=-0.143\pm0.024~{\rm MeV}^2$. Replaces ASSAMAGAN 94. 2 DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below $T_{\rm QCD}$ for wrong-helicity Divac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.
- gent limits.

 3 ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.
- **MAYLE 39 recalculates cooling rate enhancement by escape of wrong-helicity Dirac neutrinos using the Livermore Supernova Explosion Code, obtains more restrictive result than the "very conservative" BURROWS 92 limit because of higher core temperature.

 5 There would be an increased cooling rate if Dirac neutrino mass is included; this does
- not apply for Majorana neutrinos. Limit is on $\sqrt{m^2_{\nu_{\mu}} + m^2_{\nu_{\tau}}}$, and error becomes very large if ν_{τ} is nonrelativistic, which occurs near the lab limit of 31 MeV. RAJPOOT 93 notes that limit could be evaded with new physics. 6 BURROWS 92 limit for Dirac neutrinos only.

- Assumes neutrino lifetime >1 s. For Dirac neutrinos only. See also ENQVIST 93.
- ⁸ NATALE 91 published result multiplied by $\sqrt{8}\sqrt{4}$ at the advice of the author.
- $^9\,\rm GRIFOLS$ 90B estimated error is a factor of 3. $^{10}\,\rm GAEMERS$ 89 published result (< 0.03) corrected via the GANDHI 91 erratum.
- $^{11}\,\mathrm{ANDERHUB}$ 82 kinematics is insensitive to the pion mass.

Test of CPT for a Dirac neutrino. (Not a very strong test.)

- $^{12}\,\mathrm{KRAKAUER}$ 91 quotes the limit $\tau/m_{\nu_1}~>$ (0.75a^2 ~+~ 21.65a +~ 26.3) s/eV, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_{\gamma}/d{\cos} heta$ $=(1/2)(1+a\cos\theta)$ The parameter a=0 for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for a=-1).
- 13 BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained. 14 Nonobservation of γ^\prime s in coincidence with ν 's from SN 1987A. Results should be divided by the $\tau_\nu \rightarrow \gamma {\rm X}$ branching ratio.
- 15 DODELSON 92 range is for wrong-helicity keV mass Dirac ν 's from the core of neutron star in SN 1987A decaying to ν 's that would have interacted in KAM2 or IMB detectors.
