 85 AMMAR 91 cannot distinguish between doubly Cabibbo-suppressed decay and D^0 - \overline{D}^0 86 ANJOS 88C uses decay-time information to distinguish doubly Cabibbo-suppressed (DCS) decays from D^0 - \overline{D}^0 mixing. However, the result assumes no interference between the DCS and mixing amplitudes. When interference is allowed, the limit degrades to 0.033.

- 103 This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88c find the ratio of cross sections (neutral to charged) to be $1.36 \pm 0.23 \pm 0.14$. 104 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.
- may amount to a tew percent correction.

 105 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.
- to a few percent correction.
 106 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a χ^2 = 0.5 for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

$$x_2 \quad \boxed{-100}{x_1}$$

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 3 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 0.0 for 1 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left<\delta x_i \delta x_j \right>/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{ ext{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

$$\begin{array}{c|cccc} x_2 & -55 & \\ x_3 & 0 & -83 \\ \hline & x_1 & x_2 \end{array}$$

CHARMED, STRANGE MESONS $(C = S = \pm 1)$

 $D_s^+ = c\overline{s}$, $D_s^- = \overline{c}s$, similarly for D_s^* 's

D_s^\pm was F^\pm

$$I(J^P) = 0(0^-)$$

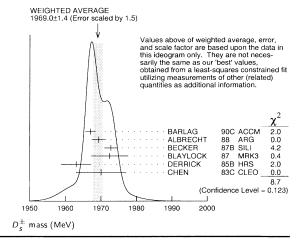

The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\,\overline{s}$ ground state.

D_s^{\pm} MASS

The fit includes D^\pm , D^0 , D_s^\pm , $D^{*\pm}$, D^{*0} , and $D_s^{*\pm}$ mass and mass difference measurements. Measurements of the D_s^\pm mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

[a] For now, we average together measurements of the $\phi\,e^+\,\nu_e$ and $\phi\,\mu^+\,\nu_\mu$ branching fractions. This is the $\it average$, not the $\it sum$.

 $(82 \pm 4)\%$

 Γ_{61} . A dummy mode used by the fit.

- [b] The branching fractions for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.
- [c] This value includes only K^+K^- decays of the $f_J(1710)$, because branching fractions of this resonance are not known.
- [d] This mode is not a useful test for a ΔC =1 weak neutral current because both quarks must change flavor in this decay.

CONSTRAINED FIT INFORMATION

An overall fit to 10 branching ratios uses 18 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2=8.3$ for 11 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta \kappa_i \delta \kappa_j \right\rangle / \left(\delta \kappa_i \cdot \delta \kappa_j \right)$, in percent, from the fit to the branching fractions, $\kappa_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the κ_i whose labels appear in this array to sum to one

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: ${}^*B^\pm/B^0$ Admixture" for $\Upsilon(4S)$ results and ${}^*B^\pm/B^0/B_S^0/b$ -baryon Admixture" for results at higher energies. Most inclusive decay branching fractions are found in the Admixture sections. $B^0 \cdot \overline{B}^0$ mixing data are found in the B^0 section, while $B_s^0 \cdot \overline{B}_s^0$ mixing data and $B \cdot \overline{B}$ mixing data for a B^0/B_s^0 admixture are found in the B^0 section. CP-violation data are found in the B^0 section. B^0 -baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

PRODUCTION AND DECAY OF b-FLAVORED HADRONS

K. Honscheid, Ohio State University, Columbus

In the two years since the last edition of this review our understanding of the physics of B mesons and b-flavored baryons has significantly improved. 1995 was another record setting year for the CLEO experiment as well as the Cornell e^+e^- storage ring (CESR) which reached an instantaneous luminosity of 3.3×10^{32} cm⁻²s⁻¹. More than 4 fb⁻¹ have been logged by the CLEO Collaboration. At CERN, the Z program has been completed and each of the four LEP experiments has recorded data samples containing about 3 million Z decays, corresponding to approximately 0.7×10^6 produced $b\bar{b}$ quark pairs. The FNAL $p\overline{p}$ collider run continued throughout most of 1995 and the CDF and DØ experiments have collected close to 100 pb⁻¹ of new data. SLD has begun to contribute to Bphysics. Using the excellent resolution of their vertex detector they have obtained precise measurements of B-meson lifetimes. New results in this edition include:

- The first observation of exclusive semileptonic $b \to u$ transitions
- The determination of the decay rate for inclusive $b \to s \gamma$ transitions.
- Updated lifetimes and masses for *b*-flavored hadrons.
- Improved measurements of $B^0 \overline{B}^0$ and $B_s^0 \overline{B}_s^0$ oscillations
- A new set of inclusive branching ratios for B mesons.
- Updated limits on rare B decays including new results on $b \rightarrow s$ gluon.

Weak decays of heavy quarks test the Standard Model and can be used to determine its parameters, in particular the weak-mixing angles of the Cabibbo-Kobayashi-Maskawa matrix. Experiments with B mesons may lead to the first precise determination of the fourth CKM parameter, the complex phase. While the underlying decay of the heavy quark is governed by the weak interaction, it is the strong force that is responsible for the formation of the hadrons that are observed by experimenters. Hence, in order to extract the Standard Model parameters from the experimental data, an understanding of the interplay of the weak and strong interaction is needed.

Production and spectroscopy

Elementary particles are characterized by their masses, lifetimes, and internal quantum numbers. The bound states with a b quark and a \overline{u} or \overline{d} antiquark are referred to as the B_d $(\overline{B^0})$ and the B_u (B^-) mesons, respectively. The first radial excitation is called the B^* meson. B^{**} is the generic name for the four orbitally excited (L=1) B meson states that correspond to the P-wave mesons in the charm system, D^{**} .

Experimental studies of b decay are performed at the $\Upsilon(4S)$ resonance near the production threshold as well as at higher energies in proton-antiproton collisions and Z decays. For quantitative analyses of B decays the initial composition of the data sample must be known. At the threshold experiments this is

b-flavored hadrons

determined by the ratio of charged to neutral decays of the $\Upsilon(4S)$. This ratio is denoted

$$\frac{f_{+}}{f_{0}} = \frac{\Upsilon(4S) \to B^{+}B^{-}}{\Upsilon(4S) \to B^{0}\overline{B}^{0}} \tag{1}$$

The $\Upsilon(4S)$ resonance decays only to $B^0\overline{B}^0$ and B^+B^- pairs, while heavier states such as B_s or B_c are not accessible. The current experimental limit for non- $B\overline{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level [1]. CLEO has measured the production ratio using semileptonic B decays and found [2]

$$\frac{f_{+}}{f_{0}} = 1.13 \pm 0.14 \pm 0.13 \pm 0.06 \tag{2}$$

where the last error is due to the uncertainties in the ratio of B^0 and B^+ lifetimes. This is consistent with equal production of B^+B^- and $B^0\overline{B}^0$ pairs and unless explicitly stated otherwise we will assume $f_+/f_0=1$. This assumption is further supported by the near equality of the B^+ and B^0 masses.

At high energy collider experiments the b quarks hadronize as B_d , B_u , B_s , and B_c mesons or as baryons containing b quarks. The composition of the initial sample is not very precisely known although over the last year significant improvements have been achieved. Several methods have been developed to determine f_{B_s} and f_{Λ_b} , the fractions of B_s mesons, and b-flavored baryons produced in $Z \to b\bar{b}$ decays. ALEPH use their measurement of the product branching fraction, $f_{B_s} \times B(\overline{B}_s^0 \to D_s^+ \ell^- \overline{\nu}_\ell$ anything) = $0.82 \pm 0.09^{+0.13}_{-0.14}\%$ [3]. Under the assumption of equal semileptonic partial widths for b-flavored hadrons results from the $\Upsilon(4S)$ experiments can be used to obtain an estimate for $B(\overline{B}_s^0 \to D_s^+ \ell^- \overline{\nu}_\ell)$. Using these results ALEPH [4] extract the fraction of b quarks that hadronize to B_s mesons to[†]

$$f_{B_8} = 11.1_{-2.6}^{+2.5}\% \tag{3}$$

A similar procedure is followed to obtain an estimate for the fraction of b baryons [5]:

$$f_{A_h} = 13.2 \pm 2.4 \pm 3.3\% \tag{4}$$

An alternative methods to determine f_{B_s} starts with the time integrated mixing parameter

$$\overline{\chi} = f_{B_o} \chi_s + f_{B^0} \chi_d \tag{5}$$

Assuming $\chi_s=0.5$ and using the measured value for χ_d the fraction of B_s mesons can be extracted [6]

$$f_{B_8} = 11.3^{+2.5}_{-2.6}\% (6)$$

Averaging the two measurements of f_{B_s} with correlated systematics taken into account yields

$$\langle f_{B_s} \rangle = 11.2^{+1.8}_{-1.9}\%$$
 (7)

Assuming that $f_{B^0}=f_{B^+}$ and $f_{B^0}+f_{B^+}+f_{B_s}+f_{A_b}=1$ we obtain the results listed in Table 1.

Table 1: Fractions of weakly decaying b-hadron species in $Z \to b\bar{b}$ decay.

b-hadron	Fraction [%]
B^+ B^0 B_s Λ_b	37.8 ± 2.2 37.8 ± 2.2 $11.2^{+1.8}_{-1.9}$ 13.2 ± 4.1

To date, the existence of four b-flavored mesons $(B^-, \overline{B}^0, B^*, B_s)$ has been established. The LEP experiments have provided evidence for excited B^{**} and B_s^{**} states. The B_c is still not observed. The A_b baryon has been exclusively reconstructed by CDF and the LEP experiments. First indications of Σ_b and Ξ_b production have been presented by the LEP collaborations [7]. DELPHI has measured the $\Sigma_b^* - \Sigma_b$ hyperfine splitting to 56 ± 16 MeV [8].

Lifetimes

The lifetime of a b-flavored hadron is given by its hadronic and semileptonic decay rates

$$\frac{1}{\tau_B} = \Gamma_{\text{tot}} = \Gamma_{\text{hadronic}} + \Gamma_{\text{semileptonic}} \tag{8}$$

In the naive spectator model the heavy quark can decay only via the external spectator mechanism and thus the lifetimes of all mesons and baryons containing b quarks would be equal. Nonspectator effects such as the interference between contributing amplitudes modify this simple picture and give rise to a lifetimes hierarchy for b-flavored hadrons similar to the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variation in the b system should be significantly smaller, of order 10% or less [9]. For the b system we expect

$$\tau(B^{-}) \geq \tau(\overline{B}^{0}) \approx \tau(B_{s}) > \tau(\Lambda_{b}^{0}) \tag{9}$$

Measurements of lifetimes for the various b-flavored hadrons thus provide a means to determine the importance of nonspectator mechanisms in the b sector.

The experimental errors on individual B-lifetime measurements are approaching the 5-10% level. However, in order to reach the precision necessary to test theoretical predictions, the results from different experiments need to be averaged. Using the conventional approach of weighting the measurements according to their error does not take into account the underlying exponential lifetime distribution. If a measurement fluctuates low then its weight in the average will increase, leading to a bias towards low values. Combining lifetime measurements correctly is a difficult task that requires detailed knowledge of common systematic uncertainties and correlations between the results from different experiments. The average lifetimes for b-flavored hadrons given in this edition have been determined by L. Di Ciaccio (DELPHI) and the LEP B Lifetimes Working Group. Among other things, they considered uncertainties in the composition of the b sample and background, correlation

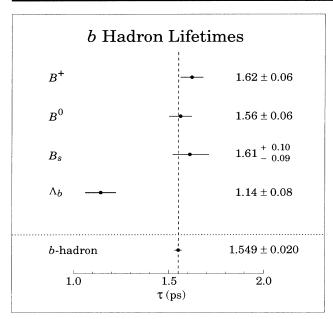

Figure 1: Summary of lifetime measurements for individual b hadrons and for the b-hadron admixture at high energy (LEP and CDF).

in the b momentum estimation and common errors in b and c branching fractions. A detailed description of their procedures and the treatment of correlated and uncorrelated errors can be found in [10]. The experimental papers used in this calculation are given in the Particle Listing sections on b-flavored mesons and baryons. A summary of the average b-hadron lifetimes is shown in Fig. 1. The pattern of measured lifetimes follows the theoretical expectations outlined above and nonspectator effects are observed to be small. However, the Λ_b baryon lifetime is unexpectedly short. As has been noted by several authors, the observed value of the Λ_b lifetime is quite difficult to accommodate theoretically [11,12].

Semileptonic decays and mixing

Measurements of semileptonic B decays are important for the determination of the weak couplings $|V_{cb}|$ and $|V_{ub}|$ and test our understanding of the dynamics of heavy quark decay. A measurement technique using events with two leptons was introduced by the ARGUS experiment [13] which significantly reduces the model dependence associated with the subtraction of the $b \to c \to \ell$ cascade component. A high momentum lepton is selected $(p_{\ell} > 1.4 \text{ GeV})$ which tags a $b\bar{b}$ event. This primary lepton is then combined with an additional lepton candidate which has a momentum above 0.5 GeV. In the absence of mixing, if the second lepton has a charge opposite to the tagging lepton it is a primary lepton from the b decay, while if the second lepton has the same sign as the tag it is a cascade lepton. Models of semileptonic B decay are only needed for

the small extrapolation to zero lepton momentum. Using this method, CLEO II finds

$$B_{sl} = (10.49 \pm 0.17 \pm 0.43)\% \tag{10}$$

consistent with the conventional single lepton analysis.

Assuming the semileptonic decay width is the same for all b-flavored hadrons, the semileptonic branching ratio should be slightly different at LEP since other b particles are produced:

$$B_{sl}(\Upsilon(4S)) = \frac{\Gamma_{sl}}{\Gamma_{tot}} = \Gamma_{sl} \times \frac{(\tau_{B^+} + \tau_{B^0})}{2}$$
 (11)

while

$$B_{\rm sl}(Z) = \Gamma_{\rm sl} \times \tau_b \tag{12}$$

Using the world averages for the B lifetimes and the CLEO semileptonic branching fraction this gives

$$B_{\rm sl}(Z) = \frac{2\tau_b}{(\tau_{B^+} + \tau_{B^0})} \times B_{\rm sl}(\Upsilon(4S)) = 10.2 \pm 0.4\%$$
 (13)

Note that the contribution of other hadrons reduces the expected average semileptonic branching fraction at the Z. This is below the experimental average from LEP, $B_{\rm sl}(Z)=10.9\pm0.1\pm0.3$, but the errors are still too large to draw any conclusions.

It is interesting to compare the inclusive semileptonic branching fraction to the sum of branching fractions for exclusive modes. CLEO and the LEP collaborations have updated their measurements of $B(B \to D\ell\nu_{\ell})$ and $B(B \to D^*\ell\nu_{\ell})$. Including the recent observations of $B \to D^{**}(2420)\ell\nu_{\ell}$ and $B \to D^{**}(2460)$ by OPAL and ALEPH the sum of exclusive semileptonic branching fractions amounts to $8.81 \pm 0.1\%$. The remaining decays may correspond to $B \to D^{**}\ell\nu_{\ell}$ where D^{**} denotes a p-wave charmed meson with a large width (e.g. the very broad but as of now unobserved $1^3P_1(2490)$ and $1^3P_0(2440)$ states). It is also possible that the other missing decays are $B \to D\pi \ell^- \nu_\ell$ where the $D\pi$ system is nonresonant or originates from the decay of a broad excited charm meson. These possibilities are difficult to check experimentally. It is also conceivable that the difference between the sum of the exclusive modes and the inclusive semileptonic rate is due to a systematic error in the D meson absolute branching fraction scale.

The ALEPH, DELPHI, OPAL, and CDF experiments have performed explicit measurements of $\operatorname{Prob}(B^0 \to \overline{B^0})$ as a function of time to obtain the parameter $x_d = \Delta m_d/\Gamma$ [6]. The initial state b quark flavor is tagged either using leptons or jet charge, while the flavor of the final state b quark is tagged using either $\overline{B}_d \to D^{*+}\ell^-X$, $\overline{B}_d \to D^{*+}X$, or $\overline{B}_d \to \ell^-X$. If the final state is not fully reconstructed, as is the case for the analyses using dileptons, then the decay time must be determined using a topological vertexing technique where the lepton from the B decay and the other tracks in the same jet hemisphere are combined. The boost is determined using the observed energy, missing momentum and a correction factor determined from a Monte Carlo simulation. Averaging these results gives $\Delta m_d = 0.458 \pm 0.020 \, \mathrm{ps}^{-1}$ which is statistically superior to

b-flavored hadrons

the results obtained from time integrated measurements by experiments at the $\Upsilon(4S)$.

The measurement of the mixing parameter $x_s = \Delta m_s/\Gamma$ for the B_s meson combined with the results on $B^0-\overline{B}^0$ oscillations allows the determination of the ratio of the CKM matrix elements $|V_{td}|^2/|V_{ts}|^2$ with significantly reduced theoretical uncertainties. Experimentally the measurement of x_s is a challenge. For large values, as expected for the B_s meson, time integrated measurements of B_s mixing become insensitive to x_s and one must make time dependent measurements in order to extract this parameter. These are very difficult because of the rapid oscillation rate of the B_s meson. Using an event sample with a lepton and a tag based on a jet charge technique where each track is weighted by its rapidity, ALEPH has searched for a high frequency component in their fit to the proper time distribution. They find $\Delta m_s > 6 \text{ ps}^{-1}$ or $x_s > 8.8$ at the 95% confidence level [6].

Hadronic decays

CLEO has presented a set of new measurements of inclusive B-meson decay rates that can be used to test the parton level expectation that most B decays proceed via a $b \to c$ transition. If we neglect the small contributions from $b \to u$ and penguin transitions, we expect about 1.15 charm quarks to be produced per B decay. The additional 15% is due to the fact that the virtual W forms a $s\bar{c}$ quark pair with a probability of approximately 0.15. This expectation can be verified experimentally by adding all inclusive $b \to c$ branching fractions. Using the world averages for the $b \to c$ branching fractions we find [14]:

Charm yield = B(
$$B \to D^0 X$$
) + B($B \to D^+ X$) + B($B \to D_s X$)
+ B($B \to A_c X$) + B($B \to \Xi_c^+ X$) + B($B \to \Xi_c^0 X$)
+ 2 × B($B \to \psi X$) + 2 × B($B \to \psi' X$)
+ 2 × B($B \to \chi_{c1} X$) + 2 × B($B \to \chi_{c2} X$)
+ 2 × B($B \to \eta_c X$ (incl. other $c\bar{c}$))
= 1.15 ± 0.05 (14)

The factor of 2 which multiplies $B(B \to c\bar{c}X)$ accounts for the two charm quarks produced in $b \to c\bar{c}s$ transitions. Wherever possible the branching fractions for direct production are used. The contribution of $B \to \eta_c X$ and other charmonia is generously taken to be at the CLEO 90% confidence level upper limit $B(B \to \eta_c X) < 0.90\%$.

Another interesting quantity is the fraction of B decays in which two charm quarks are produced. In a parton level calculation, Palmer and Stech [15] find that $B(B \to X_{c\overline{c}}) = 19 \pm 1\%$ where the theoretical error is the uncertainty due to

the choice of quark masses. This can be compared to the sum of the experimental measurements [14]

$$B(B \to X_{c\overline{c}}) = B(B \to D_s X) + B(B \to \psi X) + B(B \to \psi' X)$$

$$+ B(B \to \chi_{c1} X) + B(B \to \chi_{c2} X) + B(B \to \Xi_c X)$$

$$+ B(B \to \eta_c X \text{ (incl. other } \overline{c}))$$

$$= (15.8 \pm 2.8)\%$$
(15)

where the direct $B \to \psi$ and $B \to \chi_{c1}$ branching fraction have been used. The contribution from $B \to \Xi_c^0 X$ is reduced by 1/3 to take into account the fraction that is not produced by the $b \to c \bar{c} s$ subprocess but by $b \to c \bar{u} d + s \bar{s}$ quark popping.

A possible contribution of $B \to D\overline{D}KX$ decays, which corresponds to the quark level process $b \to c\overline{c}s$ with popping of a light quark pair, is not included in the sum calculated above. Buchalla, Dunietz, and Yamamoto have recently suggested that the latter mechanism may be significant [16]. This possibility leads to wrong sign $D\text{-}\ell$ correlations and is currently under investigation at CLEO. Preliminary results [17] indicate a significant branching fraction on the order of 10% for $B \to \overline{D}_{\text{upper vertex}} X$.

The charm yield per B-meson decay is related to an intriguing puzzle in B physics: the experimental value for the semileptonic branching ratio of B mesons is significantly below the theoretical lower bound B > 12.5% from QCD calculations within the parton model [18]. An enhanced hadronic decay rate would resolve this discrepancy and several explanations have been proposed. The theoretically preferred solution calls for an enhancement of the $b \to c\bar{c}s$ channel [19]. Increasing the $b \to c\bar{c}s$ component, however, would increase the average number of c quarks produced per b-quark decay and lead to another interesting problem: the predicted number of charm quarks per b decay would rise to 1.3 while the current experimental value for this number is 1.15 ± 0.05 . Moreover, as noted above, $B(B \to X_{c\bar{c}}) = 15.8 \pm 2.8$ is far below the required 30%. A systematic study of inclusive hadronic B decays to mesons and baryons and more precise measurements of charm meson branching fractions will be required to resolve this problem.

Measurements of exclusive hadronic B decays have reached sufficient precision to challenge our understanding of the dynamics of these decays. The factorization hypothesis has been experimentally confirmed for decays with large energy release. By comparing hadronic B^- and \overline{B}^0 decays, the relative contributions from external and internal spectator decays have been disentangled. For all decay modes studied the B^- branching ratio was found to be larger than the corresponding \overline{B}^0 branching ratio indicating constructive interference between the external and internal spectator amplitudes. This came as a surprise since destructive interference was observed in hadronic charm decay. However, the B^- modes analyzed so far comprise only a small fraction of the total hadronic rate. Further experimental study is required to determine at what level constructive interference is present in the remainder of hadronic B^- decays.

Rare decays

All B meson decays that do not occur through the usual $b \to c$ transition are known as rare B decays. The simplest diagram for a rare B decay is obtained by replacing the $b \to c$ transition by a CKM suppressed $b \to u$ transition. These decays probe the small CKM matrix element V_{ub} , the magnitude of which sets bounds on the combination $\rho^2 + \eta^2$ in the Wolfenstein parameterization of the CKM matrix. So far the only measurement of the magnitude of V_{ub} has been obtained from measurements of inclusive semileptonic B decays [20]. Last year CLEO reported the observation of exclusive semileptonic transitions. Using their large data sample and employing the excellent hermiticity of the CLEO II detector they were able to measure (using the BSW model) $B(B^0 \to \pi^- \ell^+ \nu_\ell) = (1.63 \pm 0.46 \pm 0.34) \times 10^{-4}$ and $B(B^0 \to \rho^- \ell^+ \nu_\ell) = (3.88 \pm 0.54 \pm 0.34) \times 10^{-4}$ [21].

While the errors are still large these results are an important step towards establishing a reliable value of $|V_{uh}|$.

Exclusive hadronic $b \to u$ transitions still await experimental discovery. CLEO sees a significant signal in the combined $B^0 \to \pi^+\pi^-$, $K^+\pi^-$ channels but detector resolution and statistics are not sufficient to separate the two modes.

The observation of the decay $B \to K^*(892)\gamma$, reported in 1993 by the CLEO II experiment, provided first evidence for the 1-loop penguin diagram [22]. The observed branching fractions were used to constrain a large class of Standard Model extensions [23]. However, due to the uncertainties in the hadronization, only the inclusive $b \to s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. CLEO found $B(b \to s\gamma) = (2.32 \pm 0.54 \pm 0.35) \times 10^{-4}$.

A larger total rate is expected for gluonic penguins, the counterpart of $b \to s \gamma$ with the photon replaced by a gluon. However, it is a major experimental challenge to measure the inclusive $b \to s g$ rate, where the virtual gluon hadronizes as a $q \bar{q}$ pair. Since the coupling of gluons to quark-antiquark pairs is flavor independent, it is expected that except for modifications due to phase space $b \to s \bar{s} s$ will be comparable to $b \to s \bar{u} u$, $b \to s \bar{d} d$. A recent CLEO search revealed no signal for exclusive $b \to s \bar{s} s$ decays such as $\bar{B} \to \phi K^{(*)}$ nor did they find an excess in the endpoint of the ϕ momentum spectrum for inclusive $B \to \phi$ transitions.

Outlook

With the end of the Fermilab collider run and the change of the LEP beam energies CLEO and SLD will be the only collider experiments in the next few years to collect data. While this might slow down the current rate of rapid progress in our understanding of heavy flavor physics there are still many answers hidden in the large data samples collected by CDF and the LEP collaborations. This combined with the ever-growing CLEO data sample will provide many new insights into all aspects of B physics.

The one exception is a measurement of the complex phase in CKM matrix. Data samples at least one order of magnitude

larger than those available at present are needed to observe CP asymmetries in the B-meson system and to perform one of the most fundamental consistency check of the Standard Model. This is the justification for the construction of high luminosity e^+e^- storage rings (PEP II/BaBar, CESR III/CLEO III, TRISTAN II/BELLE) as well as a dedicated fixed target experiment at the HERA ring at DESY. Hadron collider experiments dedicated to the study of CP violation have also been proposed at Fermilab and at CERN.

SEMILEPTONIC DECAYS OF B MESONS

(by J.D. Richman, University of California, Santa Barbara)

In this section, we discuss some of the key questions related to semileptonic decays of B mesons: the inclusive semileptonic branching fraction, the determination of $|V_{cb}|$ and $|V_{ub}|$ from inclusive and exclusive measurements, recent progress in exclusive semileptonic decays, and form factor measurements and tests of heavy-quark effective theory. We emphasize the uncertainties that arise in extracting $|V_{cb}|$ and $|V_{ub}|$ from data. Further discussions of these and related issues are given in the references [1,2,3]. Before addressing the experimental progress, we review the formalism of form factors for both D and B exclusive semileptonic decays. Measurements of form factors in semileptonic D decays are included in the D meson Particle Listings.

Form-factor formalism for exclusive semileptonic decays

The amplitude for an exclusive semileptonic process can be constructed from the available four-vectors in the decay and from form factors, which are Lorentz invariant functions of q^2 , the square of the mass of the virtual W. Because these functions describe the effect of strong interactions, nonperturbative techniques such as lattice QCD are needed to calculate them. Form factors are generally largest at the maximum value of q^2 , where the daughter meson has the smallest recoil velocity and the overlap between the parent- and daughter-meson wave functions is largest. Studies of form factors in D semileptonic decays have focused on the modes $D \to \overline{K}\ell^+\nu_{\ell}$ and $D \to \overline{K}^*\ell^+\nu_{\ell}$, which dominate the inclusive semileptonic rate. In B decays, the analogous modes, $B \to \overline{D}\ell^+\nu_{\ell}$ and $B \to \overline{D}^*\ell^+\nu_{\ell}$, account for about two-thirds of the inclusive semileptonic rate. The decay $B \to \overline{D}\ell^+\nu_{\ell}$ has a large background from $B \to \overline{D}^* \ell^+ \nu_{\ell}$, so in B decays, form factor measurements have focused mainly on $B \to \overline{D}^* \ell^+ \nu_{\ell}$. In this section, we discuss the formalism used in form-factor measurements for the decays $P \to P'\ell\nu_{\ell}$, where P and P' are pseudoscalar mesons, and $P \to V \ell \nu_{\ell}$, where V is a vector meson.

The differential decay rate for $P(Q\overline{q}) \to P'(q'\overline{q}) \ell \nu_{\ell}$ is

$$\frac{d\Gamma}{da^2} = \frac{G_F^2 |V_{q'Q}|^2 k_{P'}^3 |f_+(q^2)|^2}{24\pi^3} \ . \tag{1}$$

Here G_F is the Fermi decay constant, $V_{q'Q}$ is the relevant CKM matrix element, $k_{P'}$ is the momentum of P' in the rest frame of the parent meson, and $f_+(q^2)$ is a vector form factor. (Eq. (1) assumes massless charged leptons, which is almost exact for electrons and a very good approximation for muons, but it is not correct for τ 's.) The dominant q^2 dependence comes from the p-wave factor $k_{P'}^3$, which can be written in terms of q^2 and the particle masses. This factor increases the rate at low q^2 , which is opposite to the q^2 dependence of the form factor f_+ .

The exclusive decay rate for $P \to V \ell \nu_{\ell}$ can be expressed in terms of three q^2 -dependent helicity amplitudes, $H_{\pm}(q^2)$ and $H_0(q^2)$, where the subscripts indicate the helicity of either the virtual W or the vector meson. The rate is given by

$$\begin{split} \frac{d\Gamma}{dq^2\,d\cos\theta_\ell\,d\cos_V\,d\chi} &= \frac{3G_F^2|V_{q'Q}|^2\,k_V\,q^2}{8(4\pi)^4M^2} \\ \left\{ [(1+\eta\cos\theta_\ell)^2|H_+(q^2)|^2 + (1-\eta\cos\theta_\ell)^2|H_-(q^2)|^2]\sin^2\theta_V \right. \\ &+ 4\sin^2\theta_\ell\cos^2\theta_V|H_0(q^2)|^2 \\ &- 2\sin^2\theta_\ell\sin^2\theta_V\cos(2\chi)H_+(q^2)H_-(q^2) \\ &- 4\eta\sin\theta_\ell(1+\eta\cos\theta_\ell)\sin\theta_V\cos\theta_V\cos\chi\,H_+(q^2)H_0(q^2) \\ &+ 4\eta\sin\theta_\ell(1-\eta\cos\theta_\ell)\sin\theta_V\cos\theta_V\cos\chi\,H_-(q^2)H_0(q^2) \right\} \,. \end{split}$$

Here M is the mass of the parent meson, k_V is the momentum of the vector meson and is a function of q^2 , and the factor $\eta{=}{+}1$ ($\eta=-1$) applies to B (D) decays. The angles θ_ℓ , θ_V , and χ are defined in Fig. 1. The helicity amplitudes H_\pm and H_0 can be expressed in terms of two axial-vector form factors, $A_1(q^2)$ and $A_2(q^2)$, and a vector form factor $V(q^2)$:

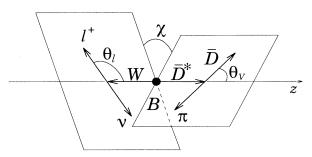

Figure 1: Definition of the angles θ_ℓ , θ_V , and χ . The decay $B \to \overline{D}^*\ell^+\nu_\ell$ is used as an example. The polar angles θ_ℓ and θ_V are defined in the rest frames of the virtual W and the \overline{D}^* , respectively, and χ is the azimuthal angle between the projections of the lepton and the \overline{D} momentum vectors in the plane perpendicular to z.

$$H_{\pm}(q^2) = (M+m)A_1(q^2) \mp \frac{2M \, k_V}{(M+m)} V(q^2)$$

$$H_0(q^2) = \frac{1}{2m\sqrt{q^2}} \Big[(M^2 - m^2 - q^2)(M+m)A_1(q^2) - \frac{4M^2 \, k_V^2}{(M+m)} A_2(q^2) \Big] , \qquad (3)$$

where m is the mass of the daughter meson. The form factors f_+ , A_1 , A_2 , and V are dimensionless.

The V-A coupling results in a larger amplitude to produce a negative-helicity vector meson in $c\overline{q}$ or $b\overline{q}$ decay than one of positive helicity: $|H_{-}| > |H_{+}|$. This difference produces a forward-backward asymmetry for the charged lepton in the virtual-W rest frame, since the net angular momentum along the decay axis of the initial heavy meson must be zero. For $D(c\overline{q})$ decays, a positively charged (right-handed) lepton is produced in association with a left-handed daughter s or dquark, resulting in a softer energy spectrum for the charged lepton than for the neutrino after boosting the lepton energy into the D rest frame. (A similar argument shows that the shape of the spectrum is the same for a \overline{D} decay.) For $\overline{B}(b\overline{q})$ decays, a negatively charged (left-handed) lepton is produced in association with a left-handed daughter quark, giving a harder energy spectrum for the charged lepton than for the neutrino in the B rest frame. In $P \to P'\ell\nu_{\ell}$ decays, there is no asymmetry, since the P' meson can only have helicity zero. Thus, the effect of V-A is to soften the inclusive lepton spectrum in D decays and to harden it in B decays. It is useful to define rates for decays into specific helicity states:

$$\Gamma_i = \frac{G_F^2 |V_{q'Q}|^2}{96\pi^3} \int dq^2 \ k_V \frac{q^2}{M^2} |H_i(q^2)|^2 \ . \tag{4}$$

Experiments extract various ratios of these rates, including Γ_+/Γ_- , $\Gamma_L/\Gamma_T = \Gamma_0/(\Gamma_- + \Gamma_+)$, the lepton forward-backward asymmetry $A_{FB} = (3\eta/4)(\Gamma_- - \Gamma_+)/\Gamma$, and the polarization parameter $\alpha = 2\Gamma_0/(\Gamma_+ + \Gamma_-) - 1$. Because the form factor A_1 appears in all three helicity amplitudes, the ratios of form factors V/A_1 and A_2/A_1 , can be obtained by fitting the measured shape of the distribution of variables q^2 , θ_ℓ , θ_V , and χ . The actual values of the form factors can be extracted from these form-factor ratios and the measured total decay rate.

The inclusive semileptonic branching fraction

The b-hadron inclusive semileptonic branching fraction, \mathcal{B}_{SL} , has been measured both at the $\Upsilon(4S)$, where the b hadrons are a mixture of B^+ and B^0 mesons, and at the Z, where B_s mesons and b baryons are produced as well. Here \mathcal{B}_{SL} is the branching fraction to either electrons or muons, not their sum. Semileptonic decays to τ leptons are suppressed by phase space and have been observed, within large errors, at the expected level [4,5]. Measurements of \mathcal{B}_{SL} are given in Table 1 for single-lepton measurements at the $\Upsilon(4S)$, in Table 2 for the LEP experiments, and in Table 3 for dilepton measurements at the $\Upsilon(4S)$.

Table 2: Measurements from LEP experiments of the inclusive b-hadron semileptonic branching fraction, $\mathrm{B}(X_{\overline{b}} \to X \ell^+ \nu_\ell)$, where X_b is a hadron containing a b-quark. At the Z, the population of b hadrons includes not only B^0 and B^+ mesons, but also a small fraction of B_s mesons and b baryons. The three errors are statistical, systematic, and the uncertainty due to model dependence.

Expt.	Ref.	$\mathrm{B}(X_{\overline{b}} \to X \ell^+ \nu_{\ell})\%$

Average		10.19 ± 0.37

Table 1: Measurements of the inclusive semileptonic branching fraction (%), $\mathcal{B}_{SL} = \mathrm{B}(B \to X \ell^+ \nu_\ell)$, averaged over the B mesons produced at the $\Upsilon(4S)$ (B^+ and B^0). These results are based on analyses of the inclusive single-lepton spectrum. Results are given separately for each of the models used to extract \mathcal{B}_{SL} . In the ARGUS measurement, the first error combines both statistical and systematic uncertainties; the second error in the ARGUS ACCMM value is due to the extra free parameters present in this model. The fit of the CLEO data using the unmodified ISGW model is poor, so the results from that fit are less reliable. The table also gives the CLEO inclusive branching fraction to charm final states ($X_{\overline{c}}$) only, which is extracted from the same fit. (Sources of error in these measurements are discussed in the text.)

Meson Particle Listings Semileptonic Decays of B's

The challenge for inclusive measurements is to determine what part of the observed lepton momentum spectrum is due to leptons from b-hadron decay (primary leptons) and what part is due to leptons from charm decay (secondary leptons) or to other sources (misidentified hadrons, photon conversions, $J/\psi(1S)$ decays, etc.). The standard technique is to fit the observed lepton momentum spectrum to a sum of the shapes expected for primary and secondary decays, after subtracting out backgrounds from other sources. Thus, a large part of the effort (and uncertainty) in the analysis is in the determination of these shapes.

Experiments at the $\Upsilon(4S)$ (ARGUS and CLEO) use theoretical models to describe the primary lepton spectrum. Some of these models have free parameters that are determined from the fit. The ACCMM model [17], for example, is based on an inclusive calculation of b-quark decay, and it has parameters corresponding to the c-quark mass and the Fermi momentum of the spectator quark, among others. A commonly used exclusive model is ISGW [18], in which the dominant contributions to the primary spectrum are from $B \to \overline{D}\ell^+\nu_{\ell}$ and $B \to \overline{D}^*\ell^+\nu_{\ell}$, with some $B \to \overline{D}^{**}\ell^+\nu_{\ell}$. Here, D^{**} refers to a mixture of p-wave and radially excited charm mesons. CLEO finds [9,10] that the amount of $B \to \overline{D}^{**} \ell^+ \nu_{\ell}$ in this model is too low to adequately describe the lepton momentum spectrum, so a modified version of the ISGW model, ISGW**, has been created. In ISGW**, the D^{**} fraction is allowed to vary, but the D^* -to-D ratio is fixed at the value (2.3) predicted by ISGW. The fit to the CLEO data using ISGW** is significantly better than that using ISGW.

The shape used to describe the secondary lepton spectrum in these fits, although somewhat more complicated to obtain, is based on data. The DELCO charm-decay lepton spectrum [19] is fit to a theoretical model (ACCMM) and then boosted according to the inclusive D-meson momentum spectrum measured at the $\Upsilon(4S)$. Future measurements should be able to use a charm lepton spectrum obtained by summing the spectra for the known exclusive charm semileptonic modes, which account for most of the inclusive rate.

LEP experiments (ALEPH, DELPHI, L3, and OPAL) measure \mathcal{B}_{SL} by fitting the spectra of p and p_T (the momentum transverse to the jet axis) in single lepton and dilepton events. The shape of the primary spectrum is taken from CLEO or ARGUS, so that model-related uncertainties in these experiments are propagated into the LEP results.

The extraction of the B semileptonic branching fraction from the momentum spectrum of single leptons, therefore, relies on models. In CLEO, which currently has the largest data sample, the spread of values obtained using different models is comparable to the experimental errors. The dominant experimental errors are due to tracking and lepton identification uncertainties.

The ARGUS collaboration [15] has introduced a second method, using dilepton events, that substantially reduces the need for models. One lepton (the "tagging lepton") is required to have high momentum and is thus nearly always primary.

The analysis then examines the momentum spectrum of the second lepton in the event. By requiring that both leptons be in the same hemisphere, events in which the two leptons come from the decay chain of a single B meson (produced nearly at rest at the $\Upsilon(4S)$) are effectively removed. Thus, (1) the tagging lepton is primary, and (2) the leptons are from different B mesons. Then, unless mixing occurs, a lepton whose charge is opposite to that of the tagging lepton must be primary, while one with the same charge as the tagging lepton must be secondary. One corrects for mixing by using the known mixing probability. The relative charges of the two leptons, therefore, can be used to separate the primary and secondary spectra of the second lepton. There is a lower momentum cutoff due to experimental acceptance, however, and a small extrapolation, based on models, is required to obtain the total semileptonic rate. The ARGUS and CLEO measurements based on this technique are listed in Table 3. This method also very much reduces the sensitivity to any possible non- $B\overline{B}$ decays of the $\Upsilon(4S)$, which are assumed to be negligible in the single-lepton method.

The values of \mathcal{B}_{SL} given in Table 1, Table 2, Table 3 are lower than most of the theoretical predictions, which give [20] $\mathcal{B}_{SL} \geq 12.5\%$. Such calculations, however, are difficult partly because they must determine the total hadronic rate, which has uncertainties associated with both perturbative and nonperturbative QCD effects. In particular, enhancements to the $b \to c\bar{c}s$ rate have been discussed as a possible explanation for the low value of \mathcal{B}_{SL} . For example, a recent analysis by Bagan, et al. [21] predicts values of \mathcal{B}_{SL} in the range 11% to 12% (with large uncertainties), as well as a somewhat larger average number, n_c , of charm quarks per decay than is found by experiment [1]. The problem of \mathcal{B}_{SL} is perhaps best rephrased as the joint problem of understanding \mathcal{B}_{SL} and n_c .

The semileptonic branching fraction can be used to calculate $|V_{cb}|$ using $\mathcal{B}_{SL} = \gamma_{\text{thy}} |V_{cb}|^2 \tau_B$, where γ_{thy} is a constant predicted by theory and τ_B is the appropriate B-hadron lifetime. Whereas the model dependence in the determination of \mathcal{B}_{SL} is associated with the predicted shapes of momentum spectra, the extraction of $|V_{cb}|$ is also sensitive to the uncertainty in $\gamma_{\rm thy}$. It is difficult to assign errors to rate predictions based on quarkmodel calculations. Quite often, a nominal theoretical error of 20% in the rate is assumed, leading to a 10% theoretical error on $|V_{cb}|$. For example, the value of $|V_{cb}|$ using the ACCMM model and the average of all experiments performing a single-lepton analysis at the $\Upsilon(4S)$ is $|V_{cb}| = 0.041 \pm 0.001 \text{ (expt)} \pm 0.004 \text{ (thy)}$ (assuming the value $\tau_B = 1.55 \pm 0.06$ ps used in Sec. 11, "The Cabibbo-Kobayashi-Maskawa Mixing Matrix"). However, some of the calculations based on heavy-quark expansions suggest that this theoretical uncertainty may be overestimated by a factor of two. HQET-based calculations have been presented by Shifman et al. [22], Luke and Savage [23], and Ball et al. [24]; this subject is controversial and is reviewed by Richman and Burchat [1], who assign a theoretical uncertainty of ± 0.003 .

The lepton endpoint region and determination of $|V_{ub}|$

The determination of $|V_{ub}|$ is one of the most important and challenging measurements in B physics. For $|V_{ub}/V_{cb}| \approx 0.1$, the rate for $B \to X_{\overline{u}}\ell^+\nu_\ell$, where $X_{\overline{u}}$ is a charmless hadronic system, is expected to be only about 1% of the inclusive semileptonic rate. By working in the region at and beyond the lepton-momentum-spectrum endpoint for $B \to X_{\overline{c}}\ell^+\nu_\ell$ processes, however, one gains enormously in sensitivity to $B \to X_{\overline{u}}\ell^+\nu_\ell$ decays.

Although the advantages of working in this endpoint region $(2.3 < p_{\ell} < 2.6 \text{ GeV/}c)$ are decisive, there are also disadvantages. A major difficulty is the need to convert the measured rate for this tiny portion of phase space into a value of $|V_{ub}|$. This calculation can be performed using either inclusive or exclusive models, but both have substantial uncertainties in predicting the rate in the endpoint region. Inclusive models are expected to be fairly reliable, if one considers a large enough part of phase space, but they may not be reliable in the endpoint region, which some theorists argue [18] is dominated by a small set of exclusive channels $(B \to \rho \ell^+ \nu_\ell, B^+ \to \omega \ell^+ \nu_\ell,$ and $B \to \pi \ell^+ \nu_{\ell}$). Alternatively, exclusive models can be used to predict the sum of contributions of individual modes in this region. However, large uncertainties exist in the calculations of the rates for exclusive modes, and some of the observed rate may be due to nonresonant final states [25]. The exclusive calculations here are more difficult than those for $B \to X_{\overline{c}} \ell^+ \nu_{\ell}$: because the u-quark mass is small, the kinematic configuration in which the final-state hadron has zero recoil velocity does not provide a reliable place to normalize the form factors, as it does in $b \to c$ decays. Furthermore, the range of recoil velocities available to the light final-state mesons in a $B \to X_{\overline{u}} \ell^+ \nu_{\ell}$ transition is much larger than for the charm mesons in a $B \to X_{\overline{c}} \ell^+ \nu_{\ell}$ decay. One therefore expects a much larger variation in the form factors. As a result, measurements of $|V_{ub}|$ are currently quite model dependent, and there is substantial variation among values obtained using different models.

The analysis of the endpoint region, although an "inclusive" measurement, is quite different from the measurement of \mathcal{B}_{SL} described in the previous section: at the $\Upsilon(4S)$, nonresonant (continuum) processes produce high-momentum leptons that constitute an enormous background (relative to a $B \to X_{\overline{u}} \ell^+ \nu_\ell$ signal) unless suppressed by kinematic cuts. The signal efficiency of these cuts is model dependent, unlike the very loose cuts used in the analysis of the inclusive lepton spectrum. In particular, the efficiency depends on the q^2 distribution of the signal events, so the value obtained for the rate in the endpoint region depends on the shape assumed for this distribution. The most important sensitivity to models, however, arises when one converts the rate to $|V_{ub}|$.

Table 4 lists the measurements of $|V_{ub}/V_{cb}|$ from CLEO and ARGUS. The CLEO-II studies, which are based on about five times as much data as either the original ARGUS or the CLEO-I analyses, yield values of $|V_{ub}/V_{cb}|$ significantly lower than the earlier measurements.

Table 4: Measurements of $|V_{ub}/V_{cb}|$ using the inclusive rate in the endpoint region. The ARGUS and CLEO-I results are each based on about 200,000 $b\bar{b}$ events, and the CLEO-II results are based on about 955,000 $b\bar{b}$ events.

Progress on exclusive semileptonic decays

In the past year, substantial progress has been made in understanding the exclusive semileptonic decays of B mesons. In particular, the observation of $B \to \pi \ell^+ \nu_\ell$ and $B \to \rho \ell^+ \nu_\ell$ by CLEO represents a milestone for these studies. In this section, we give an overview of the exclusive modes, focusing primarily on recent progress.

Measurements of exclusive semileptonic decays of B mesons are less precise and less complete than those for D mesons. Unlike D decays, where $D \to K\ell^+\nu_{\ell}$ and $D \to K^*\ell^+\nu_{\ell}$ come close to saturating the Cabibbo-favored rate, the analogous modes $B \to \overline{D}\ell^+\nu_{\ell}$ and $B \to \overline{D}^*\ell^+\nu_{\ell}$ account for only 60% to 70% of the rate for $b \rightarrow c\ell\nu_{\ell}$. The only well-measured semileptonic decay is $B \to \overline{D}^* \ell^+ \nu_{\ell}$, which has the largest branching fraction of all B decays, accounting for about 45% of the semileptonic rate. Recently, there has been some progress in improving the measurement for $B \to \overline{D}\ell^+\nu_{\ell}$ [29], which has a large background due to feed down from $B \to \overline{D}^* \ell^+ \nu_{\ell}$. Another contrast with D semileptonic decays is that the ratio of $B \to \overline{D}^* \ell^+ \nu_{\ell}$ to $B \to \overline{D} \ell^+ \nu_{\ell}$ is about 2.3, whereas in D decays the analogous vector-to-pseudoscalar ratio is about 0.6. LEP experiments [30,31] have made significant progress in observing the decays $B \to \overline{D}_1 \ell^+ \nu_{\ell}$ and $B \to \overline{D}_2^* \ell^+ \nu_{\ell}$, where the use of high-precision vertex detectors has proved to be a powerful technique for reducing combinatorial background.

The most significant recent development has been the observation [32] of exclusive charmless semileptonic decays, which should eventually lead to better determinations of $|V_{ub}|$. For these decays, unlike $B \to X_{\overline{c}} \ell^+ \nu_{\ell}$, model predictions [18] indicate that the rate should be distributed over many exclusive channels, with no dominant modes. The decays with the largest expected branching fractions are $B^0 \to \rho^- \ell^+ \nu_\ell$, $B^+ \to \rho^0 \ell^+ \nu_\ell$, and $B^+ \to \omega \ell^+ \nu_{\ell}$, which in the quark model are predicted to occur in the ratio 2:1:1. The branching fractions for $B^0 \to \pi^- \ell^+ \nu_{\ell}$ and $B^+ \to \pi^0 \ell^+ \nu_\ell$ are expected to be roughly one-third to onehalf of those for the corresponding decays to ρ mesons. For reasons that are largely independent of models, the lepton spectra for the decays to vector mesons are expected to be harder than those for the decays to pseudoscalars. CLEO has now obtained preliminary branching fractions for $B \to \pi \ell^+ \nu_{\ell}$ and $B \to \rho \ell^+ \nu_{\ell}$, which are listed in Table 5. These branching fractions are consistent with predictions based on models, assuming the value of $|V_{ub}|$ obtained from the analysis of the lepton spectrum endpoint.

Semileptonic Decays of B's

Table 5: Preliminary CLEO II branching fractions for exclusive B semileptonic decays to final states without charm. These results assume efficiencies obtained from the ISGW model [18]; if the WSB model [33] is used, the branching fractions are somewhat higher. The first error is statistical and the second systematic. The third error on the $B^0 \to \rho^- \ell^+ \nu_\ell$ branching fraction is due to a possible non-resonant $\pi\pi$ contribution.

Mode	Ref.	Branching fraction
$B^0 \to \rho^- \ell^+ \nu_\ell$ $B^0 \to \pi^- \ell^+ \nu_\ell$	[32] [32]	$(2.28 \pm 0.36 \pm 0.59^{+0.00}_{-0.46}) \times 10^{-4}$ $(1.34 \pm 0.35 \pm 0.28) \times 10^{-4}$

Measurement of $|V_{cb}|$ from $B \to \overline{D}^* \ell^+ \nu_{\ell}$

Three types of measurements can be used to determine $|V_{cb}|$: (1) the inclusive semileptonic rate (discussed above), (2) the rates for $B \to \overline{D}\ell^+\nu_\ell$ or $B \to \overline{D}^*\ell^+\nu_\ell$, and (3) the partial rate for $B \to \overline{D}^*\ell^+\nu_\ell$ for the region of phase space in which the D^* recoils slowly. The $B \to \overline{D}^*\ell^+\nu_\ell$ mode is especially well suited to measuring $|V_{cb}|$. With HQET, the rate for this process can be accurately predicted (as a function of $|V_{cb}|^2$) for the kinematic configuration in which the D^* is produced at rest (with the lepton and neutrino back to back in the B rest frame). This configuration occurs when $q^2 = q^2_{\rm max} = (m_B - m_{D^*})^2$. The light constituents of the initial B meson are then essentially undisturbed by the $B \to X_{\overline{c}}\ell^+\nu_\ell$ transition, at least in the limit where the b and c quark masses are taken to be very large compared with $\Lambda_{\rm QCD}$.

In this heavy-quark symmetry (HQS) limit, all of the $B \to \overline{D}^*\ell^+\nu_\ell$ form factors are related to a single form factor, the Isgur-Wise function, which depends only on the relative four-velocities of the initial and final hadrons: $\xi = \xi(v_B \cdot v_{D^*})$. Note that $v_B \cdot v_{D^*} = \gamma_{D^*}$, where the relativistic factor γ_{D^*} is measured in the B-meson rest frame. The quantity $v \cdot v'$, where v is the initial and v' is the final meson four-velocity, is often called w or y in the literature. It is linearly related to q^2 by

$$w = v \cdot v' = \frac{M^2 + m^2 - q^2}{2Mm} \,, \tag{5}$$

where M and m are the masses of the parent and daughter mesons.

At zero recoil $(w=1 \text{ or } q^2=q_{\max}^2)$, the normalization of ξ is known in the HQS limit, $\xi(1)=1$, which means that the decay rate in this configuration can be accurately predicted as a function of $|V_{cb}|^2$. Corrections to this picture arise from hard-gluon corrections and because the masses of the b and c quarks are not truly infinite. However, the HQS-limit prediction for $B\to \overline{D}^*\ell^+\nu_\ell$ is partly protected by Luke's theorem [34], which states that at zero recoil there are no leading order $(1/m_Q)$ nonperturbative corrections at w=1, where m_Q is the mass of a heavy quark (c or b). As a consequence, the leading nonperturbative corrections to the zero-recoil decayrate prediction arise at order $1/m_Q^2$. The calculation of these corrections, which introduces some model dependence, has been

the subject of many investigations. The results are generally expressed in terms of a function $\mathcal{F}(w)$ that can be derived from the form factors and which determines the differential rate through [35]

$$\frac{1}{\tau_B} \cdot \frac{dB(B^0 \to D^{*-}\ell^+\nu_\ell)}{dw} = \frac{G_F^2}{48\pi^3} m_{D^*}^3 (m_B - m_{D^*})^2
\times \sqrt{w^2 - 1} (w+1)^2 \left[1 + \frac{4w}{w+1} \frac{1 - 2wr + r^2}{(1-r)^2} \right]
\times |V_{cb}|^2 \mathcal{F}(w)^2,$$
(6)

where $r=m_{D^*}/m_B$. The rate at zero recoil is determined by $\mathcal{F}(1)$, which is predicted to be in the range 0.89 to 0.96 [36,37,22]. These predictions can be used to determine $|V_{cb}|$ from the measured rate at zero recoil. Strictly speaking, there is no phase space for this configuration, so in practice one has to measure the rate in a small region near w=1.

Current experiments have difficulty in measuring the rate in this region due to limited statistics. The rate at zero recoil is therefore obtained by measuring the rate as a function of w and then extrapolating to w=1. This procedure introduces some model dependence because HQET does not predict the w dependence of the form factors, which involves nonperturbative QCD physics. (Several groups are using lattice QCD and QCD sum rules to predict the w dependence and are beginning to obtain interesting results [38,3].) Because the w range is small, however, the form factors are expected to have only modest variation, which is approximately linear. CLEO, ARGUS, ALEPH, and DELPHI use a variety of functional forms to parametrize the w dependence. The different extrapolations to w=1 lead to a range of values for $|V_{cb}|$. This method leads to $|V_{cb}|=0.041\pm0.003\pm0.002$, as discussed in Sec. 11, "The Cabibbo-Kobayashi-Maskawi Mixing Matrix." Thus, the inclusive and zero-recoil methods agree well. It should be noted that $|V_{cb}|$ can also be obtained from the total rates for $B \to \overline{D}\ell^+\nu_{\ell}$ and $B \to \overline{D}^* \ell^+ \nu_{\ell}$. These values tend to be somewhat lower [1]. However, the theoretical predictions for the full decay rate are expected to be less reliable than those for the zero-recoil configuration of $B \to \overline{D}^* \ell^+ \nu_{\ell}$, since the form factors must be known over the full q^2 range.

Form factor measurements

Both CLEO and ARGUS have used measurements of kinematic distributions to obtain information on the form factors for $B \to \overline{D}^* \ell^+ \nu_\ell$. In contrast to D-meson semileptonic decays, however, one expects the predictions of heavy quark effective theory to be applicable to $B \to X_{\overline{c}} \ell^+ \nu_\ell$. Here, both the initial-and final-state quarks are heavy compared with the typical hadronic scale set by $\Lambda_{\rm QCD}$.

The differential decay rate for $\overline{B}^0 \to D^{*+}\ell^+\nu_\ell$, $D^{*+} \to D^0\pi^+$ can be expressed in terms of three form factors $A_1(q^2)$, $A_2(q^2)$, and $V(q^2)$, as discussed at the beginning of this article.

In the heavy-quark symmetry limit, the form factors are related to the Isgur-Wise function ξ :

$$V(q^{2}) = A_{2}(q^{2}) = \frac{A_{1}(q^{2})}{\left[1 - \frac{q^{2}}{(m_{B} + m_{D^{*}})^{2}}\right]}$$
$$= \frac{(m_{B} + m_{D^{*}})}{2\sqrt{m_{B}m_{D^{*}}}} \xi(w) . \tag{7}$$

This limit motivates the choice of form factor ratios [3]

$$R_{1} \equiv \left[1 - \frac{q^{2}}{(m_{B} + m_{D^{*}})^{2}}\right] \frac{V(q^{2})}{A_{1}(q^{2})}$$

$$R_{2} \equiv \left[1 - \frac{q^{2}}{(m_{B} + m_{D^{*}})^{2}}\right] \frac{A_{2}(q^{2})}{A_{1}(q^{2})}, \tag{8}$$

which are predicted to be unity, independent of w, in the heavy-quark symmetry limit. For finite heavy-quark masses, R_1 and R_2 are expected to have a mild dependence on w. Note that these quantities differ from the traditional form-factor ratios $(A_2/A_1 \text{ and } V/A_1)$ used to describe charm semileptonic decays, where heavy-quark symmetry is not expected to be a good approximation. To consider departures from the heavy-quark symmetry limit but still express the form factors in a manner that makes this limit transparent, one can use

$$A_{1}(q^{2}) = \frac{m_{B} + m_{D^{*}}}{2\sqrt{m_{B}m_{D^{*}}}} \left[1 - \frac{q^{2}}{(m_{B} + m_{D^{*}})^{2}} \right] h_{A_{1}}(w) ,$$

$$A_{2}(q^{2}) = \frac{m_{B} + m_{D^{*}}}{2\sqrt{m_{B}m_{D^{*}}}} R_{2}(w) h_{A_{1}}(w) ,$$

$$V(q^{2}) = \frac{m_{B} + m_{D^{*}}}{2\sqrt{m_{B}m_{D^{*}}}} R_{1}(w) h_{A_{1}}(w) ,$$
(9)

where $h_{A_1}(w) \to \xi(w)$ in the heavy-quark symmetry limit. Departures from this limit produce two effects: deviations of $R_1(1)$ and $R_2(1)$ from unity and a slight variation of R_1 and R_2 with w.

To measure the form factors, CLEO has performed [39] a four-dimensional fit, including correlations, to the kinematic variables q^2 , $\cos\theta_\ell$, $\cos\theta_V$, and χ . (The angles are defined at the beginning of this article.) In this fit, R_1 and R_2 were assumed to be constant, while h_{A_1} was assumed to have a linear dependence on w, with slope $\rho_{A_1}^2$: $h_{A_1}(w) = h_{A_1}(1)(1-\rho_{A_1}^2(w-1))$. The preliminary fit results are

$$R_1 = 1.18 \pm 0.30 \pm 0.12$$
,
$$R_2 = 0.71 \pm 0.22 \pm 0.07$$
,
$$\rho_{A_1}^2 = 0.91 \pm 0.15 \pm 0.06$$
. (10)

The values of R_1 and R_2 are in good agreement with predictions based on HQET with corrections [3,40]. The results for R_1 and R_2 are rather insensitive both to the form assumed for $h_{A_1}(w)$ and to the mild w dependence of R_1 and R_2 suggested by these theoretical calculations. However, the value of $\rho_{A_1}^2$ is sensitive to the form of h_{A_1} . Functions with curvature, such as exponentials or pole forms, give somewhat larger values of $\rho_{A_1}^2$.

Earlier results obtained by CLEO [41,42] and ARGUS [43] obtained A_{FB} , the lepton forward-backward asymmetry, and A_{pol} , the D^* polarization, each integrated over phase space. These results are consistent with the new result discussed above [1] but have lower precision.

See $B^{\pm}/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the B^\pm Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

				a asymmetric metime errors.

⁵ Data analyzed using $D/D^*\ell X$ event vertices.

- 6 Measured mean life using fully reconstructed decays. 7 ABREU 95Q assumes B($B^0 \rightarrow D^{**-}\ell^+\nu_\ell$) = 3.2 \pm 1.7%.
- ⁸ Data analyzed using vertex-charge technique to tag B charge.
- 9 Combined result of $D/D^*\ell X$ analysis and fully reconstructed B analysis. 10 Combined ABREU 950 and ADAM 95 result.

B+ DECAY MODES

 B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE

The branching fractions listed below assume 50% $B^0 \, \overline{B}{}^0$ and 50% $B^+ \, B^$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed $D,D_{\rm S},D^*$, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the B^\pm/B^0 ADMIXTURE and $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections

See the Notes "Experimental Highlights of B Meson Production and Decay" and "Semileptonic Decays of B Mesons" at the beginning of the B^\pm Particle Listings and the Note on " B^0 – \overline{B}^0 Mixing and CP Violation in B Decay" near the end of the B^0 Particle Listings.

BO MASS

The fit uses m_{B^+} , $(m_{B^0}-m_{B^+})$, $m_{B^0_s}$, and $(m_{B^0_s}-(m_{B^+}+m_{B^0})/2)$ to determine m_{B^+} , m_{B^0} , $m_{B^0_s}$, and the mass differences. m_{B^0} data are excluded from the fit because they are not independent.

- 1 Excluded from fit because it is not independent of ABE 96B B_s^0 mass and B_s^0 -B mass
- difference. 2 These experiments all report a common systematic error 2.0 MeV. We have artificially the experiments to be treated as independent increased the systematic error to allow the experiments to be treated as independent measurements in our average. See "Treatment of Errors" section of the Introductory Text. These experiments actually measure the difference between half of $E_{\rm Cm}$ and the
- 3 ALBRECHT 90J assumes 10580 for \varUpsilon (45) mass. Supersedes ALBRECHT 87C and
- ALBRECHT 87D. AFFICIAL FOR THE PROPERTY ALBRECHT 87D assume $m_{\Upsilon(4S)} = 10^{-10}$ 10577 MeV.

$m_{B^0} - m_{B^+}$

The mass difference measurements are not independent of the B^\pm and B^0 mass measurement by the same experimenters. The fit uses $m_{B^+},$ $(m_{B^0}-m_{B^+}),$ $m_{B^0_{\varsigma}}$ and $(m_{B^0_{\varsigma}}-(m_{B^+}+m_{B^0})/2)$ to determine m_{B^+} , m_{B^0} , m_{B^0} , and the mass differences.

B⁰ MEAN LIFE

See $B^{\pm}/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the B^\pm Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- $^6_-$ Data analyzed using $D/D^*\ell X$ event vertices.
- 7 Measured mean life using fully reconstructed decays.
- 8 Measured mean life using partially reconstructed $D^*-\pi^+ X$ vertices. 9 ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 \pm 1.7%.

- 10 Data analyzed using vertex-charge technique to tag B charge. 11 AKERS 95T assumes B($B^0 \rightarrow D_S^{(*)}D^0(*)) = 5.0 \pm 0.9\%$ to find B^+/B^0 yield.
- 11 AKERS 95T assumes B($B^0 \to D_5^{(*)}D^0(*)$) = 5.0 ± 0.9% to find B^+/B^0 yield. 12 Combined result of $D/D^*\ell \times$ analysis, fully reconstructed B analysis, and partially reconstruced $D^{*-}\pi^+ \times$ analysis. 13 Combined ABREU 95Q and ADAM 95 result. 14 WAGNER 90 tagged B^0 mesons by their decays into $D^{*-}e^+\nu$ and $D^{*-}\mu^+\nu$ where the D^{*-} is tagged by its decay into $\pi^-\overline{D}^0$. 15 AVERILL 89 is an estimate of the B^0 mean lifetime assuming that $B^0 \to D^{*+} + X$ always

MEAN LIFE RATIO τ_{B^+}/τ_{B^0}

au_{B^+}/ au_{B^0} (average of direct and inferred)

VALUE DOCUMENT ID

1.02 ± 0.05 OUR AVERAGE Includes data from the 2 datablocks that follow this one.

 au_{B^+}/ au_{B^0} (direct measurements) "OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the B^\pm Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- ¹⁶ Data analyzed using $D/D^*\ell X$ vertices.
- 17 Measurement using fully reconstructed decays. 18 ABREU 95Q assumes B($B^0 \rightarrow D^{**-}\ell^+\nu_\ell$) = 3.2 \pm 1.7%.
- ¹⁹ Data analyzed using vertex-charge technique to tag B charge. ²⁰ AKERS 95T assumes $B(B^0 \to D_S^{(*)}D^{0(*)}) = 5.0 \pm 0.9\%$ to find B^+/B^0 yield.
- ²¹ Combined result of $D/D^*\ell X$ analysis and fully reconstructed B analysis.

 τ_{B^+}/τ_{B^0} (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+ . We do not use measurements which assume equal production of B^0 and B^+ because of the large uncertainty in the production ratio.

<u>VALUE</u> <u>CL% EVTS</u> <u>DOCUMENT ID</u> <u>TECN COMMENT</u>
The data in this block is included in the average printed for a previous datablock. 22 ATHANAC

$0.93 \pm 0.18 \pm 0.12$	22	ATHANAS	94 CLE2	$e^+e^- \rightarrow$	7(45)
 ● ● We do not 	use the following of	lata for averages	, fits, limits,	etc. • • •

- 22 ATHANAS 94 uses events tagged by fully reconstructed B^- decays and partially or fully reconstructed B^0 decays.
- ²³ Assumes equal production of B^0 and B^+ .

Mode

- ²⁴ ALBRECHT 92G data analyzed using $B \to D_S \overline{D}$, $D_S \overline{D}^*$, $D_S^* \overline{D}$, $D_S^* \overline{D}^*$ events.
- 25 BEAN 87B assume the fraction of $B^0\overline{B}^0$ events at the $\Upsilon(4S)$ is 0.41.

B⁰ DECAY MODES

 $\overline{\it B}{}^{0}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE

The branching fractions listed below assume 50% $B^0\,\overline{B}{}^0$ and 50% $B^+\,B^$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed $D,\ D_s,\ D^*$, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

47 37 ALBRECHT 87J ARG $e^+e^- \rightarrow \Upsilon(4S)$ $0.070 \pm 0.012 \pm 0.019$ ²⁸ BARISH 95 use B($D^0 \to K^- \pi^+$) = (3.91 ± 0.08 ± 0.17)% and B($D^{*+} \to D^0 \pi^+$) $(68.1 \pm 1.0 \pm 1.3)\%$.

²⁹ BUSKULIC 95N assumes fraction (B^+) = fraction (B^0) = 38.2 \pm 1.3 \pm 2.2% and au_{B^0} $= 1.58 \pm 0.06$ ps. $\Gamma(D^{*-}\ell^+\nu_\ell)/{
m total} = [5.18 - 0.13({
m fraction}(B^0) - 38.2) - 1.5(au_{B^0} - 1.5)$

³⁰ ALBRECHT 94 assumes B($D^{*+} \rightarrow D^0 \pi^+$) = 68.1 \pm 1.0 \pm 1.3%. Uses partial reconstruction of D^{*+} and is independent of D^{0} branching ratios.

 $31\,\text{ALBRECHT}$ 93 reports 0.052 \pm 0.005 \pm 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0\to K^-\pi^+$). We have taken their average e and μ value. They also obtain $\alpha=2*\Gamma^0/(\Gamma^-+\Gamma^+)-1=1.1\pm0.4\pm0.2$, $A_{AF}=3/4*(\Gamma^--\Gamma^+)/\Gamma=0.2\pm0.08\pm0.06$ and a value of $|V_{Cb}|=0.036$ depending on model assumptions.

depending on model assumptions. 32 We have taken average of the the BORTOLETTO 89B values for electrons and muons, 0.046 \pm 0.005 \pm 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \rightarrow K^-\pi^+$). The measurement suggests a D^* polarization parameter value $\alpha=0.65\pm0.66\pm0.25$. 33 Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test V-A structure and fit the

decay angular distributions to obtain $A_{FB}=3/4*(\Gamma^--\Gamma^+)/\Gamma=0.14\pm0.06\pm0.03$. Assuming a value of V_{Cb} , they measure V, A_1 , and A_2 , the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

 34 ANTREASYAN 90B is average over B and $\overline{D}^*(2010)$ charge states.

 35 The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 \pm 0.45.

36 ALBRECHT 89) is ALBRECHT 87J value rescaled using B($D^*(2010)^- \rightarrow D^0\pi^-$) = 0.57 \pm 0.04 \pm 0.04. Superseded by ALBRECHT 93.

 37 ALBRECHT 87J assume μ -e universality, the B($\Upsilon(4S) \rightarrow B^0 \overline{B}{}^0) = 0.45$, the B($D^0 \rightarrow B^0 \overline{B}{}^0$) $K^-\pi^+)=(0.042\pm0.004\pm0.004)$, and the B($D^*(2010)^-\to D^0\pi^-)=0.49\pm0.08$. Superseded by ALBRECHT 89J.

 240 AKERS 94C uses $D^{*\pm}\ell^{\mp}$ events and jet charge.

 $\mathbf{x_d} = \Delta m_{B^0} / \Gamma_{B^0}$ This section combines results from the previous two sections.

Time integrated mixing measurements of X determine this quantity directly via

$$\frac{\Delta m_{B^0}}{\Gamma_{B^0}} = \left(\frac{\chi}{0.5 - \chi}\right)^{1/2}$$

while time-dependent mixing measurements determine $\Delta m_{B^0} = m_{B^0_L} - m_{B^0_L}$ which are combined with τ_{B^0} to give

$$\frac{\Delta m_{B^0}}{\Gamma_{B^0}} = \frac{(m_{B^0_H} - m_{B^0_L})^{\tau_{B^0}}}{\hbar} \; .$$

The averaging takes into account the common systematic errors on the LEP experiments due to τ_{D0} .

²⁴¹ Value is their Δm_{B0} measurement combined with $\tau_{B0}=(1.56\pm0.06)$ ps, the average from this edition. The systematic error on τ_{B} and is common to experiments bearing this footnote. The averaging takes this into account.

$B^0-\overline{B}{}^0$ MIXING AND CP VIOLATION IN B DECAY (by H. Quinn, SLAC)

The neutral B meson system is like the neutral kaon system, in that two CP-conjugate states exist. For early work on CPviolation in the B system see Ref. 1. The mass eigenstates are not CP eigenstates, but are mixtures of the two CP-conjugate quark states, the mixing being due to box diagrams, shown in Figure 1. The two mass eigenstates can be written

$$|B_L\rangle = p|B^0\rangle + q|\overline{B}^0\rangle$$
,
 $|B_H\rangle = p|B^0\rangle - q|\overline{B}^0\rangle$. (1)

Here H and L stand for Heavy and Light, respectively.

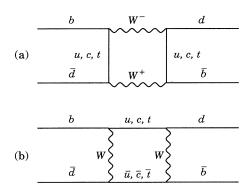

Figure 1: Mixing Diagrams.

Whereas in the kaon case the lifetimes of the two eigenstates are significantly different and the difference in masses between them is small, in the B system it is the mass differences that dominate the physics, and the two states have nearly equal predicted widths (and thus lifetimes).

$$\Gamma = (\Gamma_H + \Gamma_L)/2 , \ \Delta \Gamma = \Gamma_H - \Gamma_L .$$
 (2)

The difference between the widths of the two eigenstates is produced by the contributions from channels to which both B^0 and \overline{B}^0 can decay. These have branching ratios of $\mathcal{O}(10^{-3})$ [2]. Furthermore there are contributions of both signs to the difference, so there is no reason that the net effect should be much larger than the individual terms. Conservatively, one expects $\Delta\Gamma/\Gamma < 10^{-2}$. Experimentally no effect of a difference in lifetimes has been observed. In what follows, we neglect any effects from $\Delta\Gamma$, except where explicitly stated. We define also

$$M \equiv (M_H + M_L)/2 , \quad \Delta M \equiv M_H - M_L .$$
 (3)

²⁴² Derived from time-integrated mixing parameter χ .

The proper time evolution of an initially (t=0) pure B^0 or $\overline{B}{}^0$ is given by

$$\begin{split} |B^0_{\rm phys}(t)\rangle &= \\ &\exp(-\Gamma t/2) \exp(-iMt) \\ &\quad \times \{\cos(\Delta M t/2) |B^0\rangle + i(q/p) \sin(\Delta M t/2) |\overline{B}^0\rangle \} \ , \\ |\overline{B}^0_{\rm phys}(t)\rangle &= \\ &\exp(-\Gamma t/2) \exp(-iMt) \\ &\quad \times \{i(p/q) \sin(\Delta M t/2) |B^0\rangle + \cos(\Delta M t/2) |\overline{B}^0\rangle \} \ . \ (4) \end{split}$$

The probability that an initial B^0 ($\overline{B}{}^0$) decays as a $\overline{B}{}^0$ (B^0) is thus

$$P(t) = \frac{1}{2}e^{-\Gamma t}(1 - \cos(\Delta M t)) \tag{5}$$

where we have used |p/q| = 1 which is true when we neglect the effects of $\Delta\Gamma$. Time-dependent mixing measurements are now being done; earlier experiments measured only the timeintegrated mixing, which is parameterized by a parameter \mathcal{X}_d for B_d (i.e., B^0) and \mathcal{X}_s for B_s (i.e., B_s^0). The quantity \mathcal{X} measures the total probability that a created B^0 decays as a \overline{B}^0 ; it is given by

$$\chi_q = \int_0^\infty P_q(t)dt = \frac{x_q^2}{2(1+x_q^2)} ,$$
 (6)

where q=d,s and $x_q=\frac{\Delta M_q}{\Gamma_q}$, the ratio of the $B_q^0-\overline{B}_q^0$ oscillation frequency to the decay rate. The value of x_d is about 0.7, not very different from the similar quantity for the K^0 which is 0.48. The value of x_s is expected to be much larger, so that the quantity χ_s will be close to its upper limit of 0.5. This means that one cannot determine x_s accurately by measuring χ_s . It will require excellent time resolution to resolve the time-dependent mixing of the B_s^0 system, and thereby determine $\Delta M_{B_s^0}$ [3].

In the B^0 – \overline{B}^0 mixing section of the B^0 Particle Listings, we list the χ_d measurements, most of which come from $\Upsilon(4S)$ data, and the Δm_{B^0} measurements, which come from Z data. We average these sections separately, but then include the results from both sections in "OUR EVALUATION" of χ_s and $\Delta M_{B_s^0}$. We convert both of these sets of measurements and list them in the x_d section. The x_d values obtained from Δm_{B^0} measurements have a common systematic error due to the error on τ_{B^0} . The averaging takes this common systematic error into account.

In the B_s^0 – \overline{B}_s^0 mixing section of the B_s^0 Particle Listings, we give measurements of χ_B , the mixing parameter for a high-energy admixture of b-hadrons

$$\chi_B = f_d \frac{\mathcal{B}_d}{\langle \mathcal{B} \rangle} \chi_d + f_s \frac{\mathcal{B}_s}{\langle \mathcal{B} \rangle} \chi_s . \tag{7}$$

Here f_d and f_s are the fractions of b hadrons that are produced as B^0 and B_s^0 mesons respectively, and \mathcal{B}_d , \mathcal{B}_s , and $\langle \mathcal{B} \rangle$ are branching fractions for B_d , B_s , and the b-hadron admixture

respectively decaying to the observed mode. If we assume that $\chi_s = 0.5$ and $\mathcal{B}_d/\langle \mathcal{B} \rangle = \mathcal{B}_s/\langle \mathcal{B} \rangle = 1$, Eq. (7) can be used to determine f_s as discussed in the note on "Production and Decay of b-Flavored Hadrons."

$CP\ violation\ in\ B\ decays-Standard\ Model\ predictions$:

There are three symmetries of the strong interactions that are not conserved in weak processes. These are the symmetries C, charge conjugation, which relates particle to antiparticle, P, parity, which relates a left-handed particle to a similar righthanded one, and T, time-reversal invariance, which relates a process or state to the time-reversed process or state. In all field theories the product of these three operations, CPT, is an exact symmetry of the equations of motion. All weak decays violate P and C, and a very small part of the weak decays also violate the product CP (and thus T). In the Standard Model this CP violation occurs because there is a single phase that remains in the Cabibbo-Kobayashi-Maskawa (CKM) matrix after all possible field redefinitions that can remove such phases have been made. In a minimal two-generation Standard Model no such phase occurs. The presence of CP-violating effects in K decays was interpreted by Kobayashi and Maskawa in 1973 to suggest a third quark generation. Other extensions beyond the minimal Standard Model, such as theories with additional Higgs multiplets, give further ways to introduce CP violation into the theory. Hence it is of great interest to study whether the pattern of CP-violating effects that can be observed in B decays follows the predictions of the minimal Standard Model, or instead requires the introduction of beyond Standard Model effects. In what follows we first discuss the predictions of the minimal Standard Model. Cosmologists attempting to understand the process by which the matter-antimatter asymmetry of the universe arose suggest that additional sources of CP violation may be needed to give the observed baryon to photon ratio of the universe [4]. Many models which go beyond the Standard Model indeed introduce such possibilities; a few of these are discussed in the final section of this review.

The CKM matrix is the matrix of weak couplings in the three generation Standard Model, expressed in the basis of quark mass eigenstates. This matrix, which must be unitary if the three generations are the complete theory, is discussed in some detail in a separate article in this *Review*. Here we need only remind ourselves of some notation that is commonly used in this context. The matrix can be written

$$V = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}$$
(8)

$$\simeq \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + O(\lambda^4) \ .$$

The second expression here is a parameterization due to Wolfenstein [5] with $\lambda = \sin(\theta_{\text{Cabibbo}})$, which is frequently used in discussing CP-violating effects. It is given here up to terms

of order λ^3 , since higher order terms in λ are negligible in most situations. For a way to include higher order terms see Ref. 6. The unitarity triangle is a simple geometrical representation of a relationship which results from the unitarity of the three-generation CKM matrix V:

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0 (9)$$

(In fact there are nine such relationships given by the unitarity of the CKM matrix, but only three are independent conditions and of those the other two will be more difficult to test because they have one term that is of order λ^2 relative to the others.) The three complex quantities $V_{id}V_{ib}^*$ form a triangle in the complex plane. The three angles of this triangle are labeled

$$\alpha \equiv \arg\left(-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right) , \quad \beta \equiv \arg\left(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right) ,$$

$$\gamma \equiv \arg\left(-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{vb}^*}\right) . \tag{10}$$

In terms of the Wolfenstein parameters we can also write

$$\tan(\alpha) = \frac{\eta}{(\eta^2 - \rho(1 - \rho))} , \quad \tan(\beta) = \frac{\eta}{(1 - \rho)} ,$$

$$\tan(\gamma) = \frac{\eta}{\rho} . \tag{11}$$

Notice that the sign as well the magnitude of these angles is meaningful and can be measured.

Figure 2 shows the unitarity triangle, as it is usually drawn, rescaled by $V_{cd}V_{cb}^*$. This makes the base of the triangle real and of unit length and the apex of the triangle is then the point (ρ, η) in the complex plane. A major aim of CP-violation studies of B decays is to make enough independent measurements of the sides and angles that this triangle is overdetermined and thus to check the validity of the Standard Model. Already a number of constraints can be made on the basis of present data on x_d , V_{ub}/V_{cb} , and ϵ in K decays. These constraints have been discussed in many places in the literature; for a recent summary see Ref. 7. Their exact form depends on the mass of the top quark and on the range of values allowed for the B_K parameter in K decays and the parameter combination $B_B f_B^2$ in B decays.

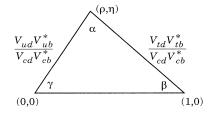

Figure 2: The (rescaled) Unitarity Triangle.

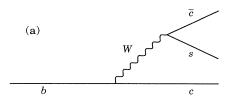

The CKM phases, that is the phases in decay amplitudes which arise because of the phase in the CKM matrix, are often called weak phases, in contrast to the phases which arise from final state rescattering effects, which are referred to as strong phases. When one compares the amplitude for decay to a CP eigenstate to that for the related CP conjugate process, the weak phase ϕ_i of each contribution changes sign, while the strong phase δ_i is unchanged:

$$\mathcal{A} = \Sigma_i \mathcal{A}_i e^{i(\delta_i + \phi_i)} , \overline{\mathcal{A}} = \Sigma_i \mathcal{A}_i e^{i(\delta_i - \phi_i)} . \tag{12}$$

Direct CP violation is a difference in the direct decay rate between $B \to f$ and $\overline{B} \to \overline{f}$ without any contribution from mixing effects. This requires $|\mathcal{A}| \neq |\overline{\mathcal{A}}|$, which occurs only if there is more than one term in the sum Eq. (12), and only if the two terms have both different weak phases and different strong phases. A nonzero result for Re ϵ' in K decay is a direct CP-violation effect. Direct CP violation can occur both in charged channels and in neutral channels.

In the Standard Model direct CP violation occurs when there are two sets of diagrams with different weak phases that contribute to the same decay. There are two major classes of diagrams that contribute to weak decays, tree diagrams and penguin diagrams, examples of which are shown in Figure 3. Tree diagrams are those in which the W does not reconnect to the quark line from which it was emitted. Penguin diagrams are loop diagrams in which the W is reabsorbed on the same quark line, producing a net change of flavor, and a gluon, photon or Z is emitted from the loop. There may be several different tree diagrams for a given process, namely emission from the heavy quark line accompanied by W decay, W exchange between the initial valence quarks, and/or valence quark-antiquark annihilation to produce the W. However all such contributions which enter a given transition do so with the same CKM (weak) phase. Thus, in the Standard Model, direct CP violation occurs because of interference between tree diagrams and penguin diagrams when these have different weak phases, or, in channels where there are no tree contributions, it can also arise because of different weak phases of different penguin contributions. This latter can be a significant effect for $b \rightarrow s\overline{s}d$ decays, as is discussed below.

To calculate the size of expected CP-violation effects one begins from the relevant quark decay diagrams. In general weak-decay amplitudes for b quarks can be divided into two factors: a CKM factor given by the CKM-matrix elements that enter at each W vertex, and a Feynman amplitude from evaluating the diagram. In addition to the suppression from being loop diagrams, penguin diagrams for B decay require the emission of a hard gluon (or photon) from the loop to account for the mass difference between the b quark and the s or d quark produced when the W is reabsorbed. The Feynman amplitude of the penguin diagram is thus suppressed relative to tree diagrams by a factor of order $\alpha_s(m_b)/4\pi$. It is difficult to make firm predictions based on this argument for the strength of the CP-violating effects in exclusive charged B-decay channels

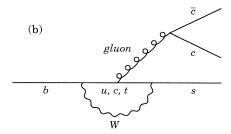

Figure 3: Quark level processes for $b \to c\overline{c}s$: (a) Tree diagram; (b) Penguin diagram. In the case of elelectroweak penguin contributions, the *gluon* is replaced by a Z or a γ .

because the relationship between the free-quark decay diagrams and the exclusive meson-decay amplitudes is model dependent. Furthermore one cannot reliably predict the strong phases that contribute to the asymmetry.

There are additional CP-violating effects in neutral B decays which arise from interference between the two paths to a given final state f

$$B \to f \text{ or } B \to \overline{B} \to f$$

This CP violation in the interference between the mixed and unmixed decay paths is sometimes called CP violation due to interference between mixing and decay. It is similar to the effect measured by the parameter Im ϵ in K decay. The interference between the two contributions can produce rate differences between the decay and its CP conjugate. These effects are of particular interest because they do not depend upon strong phases and hence the measured asymmetries can be directly related to the CKM phases. In some channels there can be direct CP violation in addition to this effect. In such channels the relationship between the measured asymmetry and the CKM parameters is more complicated. We will briefly discuss techniques to separate such contributions later in this review.

A third type of CP violation, referred to as indirect CP violation, or CP violation in the mixing, would arise from any difference in the widths $\Delta\Gamma$ of the two mass eigenstates, or more precisely from complex mixing effects that would also give a nonvanishing lifetime difference for the two B mass eigenstates. Such effects are expected to be tiny in the B_d system. For B_s a small difference in the widths is possible, due to the fact that a number of the simplest two-body channels contribute only to a single CP. The difference in widths could be as much as 20% of the total width in the B_s system [8]. In the particular case

of semileptonic decays there are no penguin diagram contributions, and hence, in the approximations used throughout the discussion above, the CP-conjugate decay rates are equal. An indirect CP-violating asymmetry would be seen as an charge asymmetry in the same-sign dilepton events produced via mixing from an incoherent state that initially contains a $B^0\overline{B}^0$ pair. This asymmetry vanishes with $\Delta\Gamma$; it is expected to be no larger than 1% in B_d decays. [9].

A simple way to distinguish the three types of CP violation is to note that direct CP violation occurs when $|\overline{\mathcal{A}}/\mathcal{A}| \neq 1$, indirect CP violation requires $|q/p| \neq 1$, but CP violation due the interference between direct decay and decay after mixing can occur when both quantities have unit absolute value; it requires only that their product have a nonzero weak phase [10].

Neutral B decays to CP eigenstates: The decays of neutral B's into CP eigenstates is of particular interest because many of these decays allow clean theoretical interpretation in terms of the parameters of the Standard Model [11]. We denote such a state by f_{CP} , for example $f_{CP} = J/\psi(1S)K_S$ or $f_{CP} = \pi\pi$, and define the amplitudes

$$\mathcal{A}_{f_{CP}} \equiv \langle f_{CP} | B^0 \rangle, \quad \overline{\mathcal{A}}_{f_{CP}} \equiv \langle f_{CP} | \overline{B}^0 \rangle$$
 (13)

For convenience let us introduce the quantity r_{fGP}

$$r_{f_{CP}} \equiv \frac{q}{p} \frac{\overline{A_{f_{CP}}}}{A_{f_{CP}}} \ . \tag{14}$$

In the limit of no CP violation, $r_{fCP}=\pm 1$, where the sign is given by the CP eigenvalue of the particular state f_{CP} . (Note that in the literature the quantity r_{fCP} is frequently denoted by λ , but we have chosen to avoid this notation as it introduces a confusion with the $\lambda=\sin(\theta_{\rm Cabibbo})$ in the Wolfenstein parameterization of the CKM matrix.)

The time-dependent rates for initially pure B^0 or $\overline{B}{}^0$ states to decay into a final state f_{CP} at time t is then given by:

$$\langle f_{CP}|B^{0}_{\rm phys}(t)\rangle =$$

$$\mathcal{A}_{f_{CP}} \exp(-\Gamma t/2) \exp(-iMt)$$

$$\times \left[\cos(\Delta Mt/2) + ir_{f_{CP}} \sin(\Delta Mt/2)\right] ,$$

$$\langle f_{CP}|\overline{B}^{0}_{\rm phys}(t)\rangle =$$

$$\mathcal{A}_{f_{CP}} \exp(-\Gamma t/2) \exp(-iMt)(p/q)$$

$$\times \left[i\sin(\Delta Mt/2) + r_{f_{CP}} \cos(\Delta Mt/2)\right] . \tag{15}$$
Thus

$$\begin{split} \Gamma(B_{\rm phys}^0(t) &\to f_{CP}) = \\ |\mathcal{A}_{f_{CP}}|^2 e^{-\Gamma t} \bigg[\frac{1 + |r_{f_{CP}}|^2}{2} + \frac{1 - |r_{f_{CP}}|^2}{2} \end{split}$$

$$\times \cos(\Delta Mt) - \operatorname{Im} r_{f_{CP}} \sin(\Delta Mt) \bigg],$$

$$B^0$$

$$\Gamma(\overline{B}_{\text{phys}}^{0}(t) \to f_{CP}) =$$

$$|\mathcal{A}_{f_{CP}}|^{2} e^{-\Gamma t} \left[\frac{1 + |r_{f_{CP}}|^{2}}{2} - \frac{1 - |r_{f_{CP}}|^{2}}{2} \right] \times \cos(\Delta M t) + \operatorname{Im} r_{f_{CP}} \sin(\Delta M t) . \tag{16}$$

The time-dependent CP asymmetry is

$$a_{f_{CP}}(t) \equiv \frac{\Gamma(B_{\text{phys}}^{0}(t) \to f_{CP}) - \Gamma(\overline{B}_{\text{phys}}^{0}(t) \to f_{CP})}{\Gamma(B_{\text{phys}}^{0}(t) \to f_{CP}) + \Gamma(\overline{B}_{\text{phys}}^{0}(t) \to f_{CP})}$$
(17)

$$a_{f_{CP}}(t) = \frac{(1 - |r_{f_{CP}}|^2)\cos(\Delta M t) - 2\text{Im}\ (r_{f_{CP}})\sin(\Delta M t)}{1 + |r_{f_{CP}}|^2}.(18)$$

When the small difference in width of the two B_d states is ignored we can write

$$(q/p)_{B_d} = \frac{(V_{tb}^* V_{td})}{(V_{tb} V_{td}^*)} , (19)$$

and thus

$$q/p = e^{-2i\phi_M} (20)$$

where $2\phi_M$ denotes the CKM phase of the $B-\overline{B}$ mixing diagram. Further, when there is no direct CP violation in a channel, that is when all amplitudes that contribute have the same CKM decay-phase, ϕ_D , then $|\mathcal{A}_{f_{CP}}/\overline{\mathcal{A}_{f_{CP}}}|=1$. In that case $r_{f_{CP}}$ depends on CKM-matrix parameters only, without hadronic uncertainties, and can be written $r_{f_{CP}}=\pm e^{-2i(\phi_D+\phi_M)}$. Then Eq. (18) simplifies to

$$a_{f_{CP}}(t) = \mp \operatorname{Im} (r_{f_{CP}}) \sin(\Delta M t)$$

= $\pm \sin(2(\phi_M + \phi_D)) \sin(\Delta M t)$. (21)

where the overall sign is given by the CP eigenvalue, ± 1 , of the final state f_{CP} . The mixing phase ϕ_M and the decay phase ϕ_D are each convention dependent, that is their value can be changed by redefining the phases of some of the quark fields. However $\operatorname{Im}\ r_{f_{CP}}$ depends on convention-independent combinations of CKM parameters only, and thus from Eq. (21) one can directly relate the measured CP-violating asymmetry to the phase of particular combination of CKM-matrix elements in the Standard Model.

In an e^+e^- B collider running at the $\Upsilon(4S)$ resonance, the initial B system is produced in a definite CP-eigenstate state which evolves coherently and thus remains $B^0\overline{B}{}^0$ until such time as one of the particles decays. The time evolution of the second particle to decay thus begins at the time of the first decay. Events where one B decays to a flavor-tagging mode while the other decays to a CP-study mode can be used to reconstruct the dependence of the asymmetry on the time between the tagging decay and the CP-study mode decay. The tagging decay may be later, in which case the event is assigned a negative time. Note that the measurement of time dependence is essential at such a machine since, in the interesting cases where Eq. (21) applies, the time-integrated CP asymmetry vanishes.

Hadron machines on the other hand produce uncorrelated B and \overline{B} mesons. In that case the time in the above equations is the time between production and decay, which is always positive, so time-integrated asymmetries do not vanish. Both the tagging particle and the particle decaying to the CP-study mode evolve through mixing, beginning from the time of production. Such machines produce many more B's than will an e^+e^- B factory but the necessity of triggering selections to isolate B events reduces the effective signal somewhat. In addition there are significant backgrounds to contend with in purely hadronic channels, so those channels with leptonic signatures are more readily studied in this environment. The results from the two types of machines will have many complementary features.

Extracting CKM parameters from measured asymmetries: In order to relate the measured asymmetries to the CKM-matrix parameters one looks at the CKM elements that appear in the relevant decay amplitudes and in the mixing diagrams. If the final state of the decay includes a K_S , an additional contribution from the K-mixing phase must be included in relating the measured asymmetry to the CKM parameters.

Table 1 gives the CKM factors for the various b-quark decay channels. For penguin diagrams the table gives the CKM factor of the dominant contributions. Unitarity of the CKM matrix is used to re-express the three different up-type quark loop contributions as a sum of two terms, one of which dominates the contribution. In the case of $b \to d$ processes the subdominant term is suppressed by a term which vanishes with the difference between charm and up quark masses. In the case of $b \to s$ decays the subdominant penguin amplitudes are suppressed by two powers of λ relative to the dominant term given here.

The columns labeled "Sample B_d Modes" and "Sample B_s Modes" list some of the simplest CP-study modes for each case. (These are either CP eigenstates, or modes from which CP-eigenstate contributions can be isolated, for example by angular analysis.) The columns labeled "Angle" show the particular combination of CKM phases $\phi_M + \phi_D$ that is measured by the CP-violating asymmetry in these decays, given as an angle of the unitarity triangle. For most channels the measured asymmetry in a time-dependent measurement is $\pm \sin(2(\phi_M + \phi_D))\sin(\Delta Mt)$. For a time-integrated measurement (uncorrelated production) the asymmetry is $\pm (x_q/(1+x_q^2))\sin(2(\phi_M+\phi_D))$. The sign is given by the CP eigenvalue of the particular final state studied. (The exception to these statements is the channel DK discussed below.)

In obtaining the results given in the table several simplifying approximations have been used. Terms of higher order in $\lambda =$ $\sin(\theta_{\text{Cabibbo}})$ have been dropped. Penguin diagrams that occur at the same order of λ as the corresponding tree diagrams are neglected in stating the relationship of the asymmetry to angles in the unitarity triangle. The comments below the table state

 B^0

where these assumptions are used. Even with these assumptions there are cases where the tree and penguin diagrams are expected to give comparable contributions with different CKM phases. For these decays, as with other direct CP-violating processes, there is no simple relationship between the measured asymmetry and a CKM phase, and thus no entry in the "Angle" columns in Table 1.

The mode $D^0K^*(892)$ is listed even though it is not a CP eigenstate because it has been shown that an analysis of this mode can be used to extract the angle γ [12]. The same type of analysis can also be applied to charged B decays [13]. However the relationship between the decay asymmetry and the angle is not as simple as Eq. (21) in this case. The result will require accurate measurements of a number of branching ratios.

In the case of the $b \to u\overline{u}d + d\overline{d}d$, the penguin contributions occur at the same order in λ as the tree diagrams and are thus are expected to be small compared to them because of the $\alpha(m_b)/\pi$ suppression factor. The result given in Table 1 makes this approximation. If however this expectation proves false, so that the contribu-

tions are comparable, one still may be able to extract a measurement of $\sin(2\alpha)$ from the $\pi^+\pi^-$ asymmetry. This is achieved by measuring the rates in several isospin-related channels and using a multiparameter fit to separate tree and penguin contributions to the amplitudes [14]. The impact of electroweak penguins. which will not be removed by this analysis [15] is quite small in this channel. [16] The isospin analysis will require measuring the decay rate for channel $\pi^0\pi^0$, which will be a challenge. For the $\rho\pi$ decays, if penguins are not negligible, the restrictions due to isospin can again be used to make a multiparameter fit to the ρ -regions of the Dalitz plot for $\pi^+\pi^-\pi^0$ distribution [17]. The interference between different ρ -charge channels is significant and may provide sufficient information to allow the separation of tree and penguin effects and thus extraction of the parameter α . Such analyses at the very least can be used to test whether the penguin contributions are indeed small enough to be neglected in the determination of α .

In the case $b \to s\overline{s}d$ there are no tree graph contributions. The phase of the dominant penguin contribution is such that, combined with mixing effects, it gives a zero asymmetry for

⁽a) Tree and penguin contribute with same weak phase.

⁽b) Penguin only, rare decays.

⁽c) Tree and penguin compete. Isospin analysis may allow extraction of α , β , for B_d channels, γ , 0 for B_s , where these angles come from tree and penguin contributions respectively. $K_S\overline{K}_S$ penguin only, except 0 asymmetry.

⁽d) Ignoring penguin relative to tree.

 $[\]left(e\right)$ Ignoring penguin relative to tree, or using isospin analysis.

⁽f) Self-tagging $K^*(892)$ decay modes can give γ when data from $B_d \to D^0_{CP}$, i.e. decays to CP eigenstates, and D^0 - or \overline{D}^0 -identified modes are combined. Similar results for charged $B \to DK$.

⁽g) Asymmetry in $D^0_{CP}\pi$, $D^0_{CP}K_S$, etc. modes is difficult to relate to CKM angles.

^(†) $D^0\overline{D}^0$ from rescattering only, rate expected to be small.

 B_d decays and an asymmetry proportional to β for B_s decays. However, Gérard and Hou [18] have pointed out that the sub-dominant penguin terms, proportional to $V_{ub}V_{ud}^*$ can give significant direct CP-violation asymmetries for such channels. Fleischer [19] has estimated that this asymmetry is possibly as large as 50%. While the sub-dominant term in this case would vanish if the masses of the up quark and the charm quark were equal, these estimates, based on the actual quark mass values and operator matrix elements estimated using models, cannot be excluded. Thus, contrary to some comments in the literature, observation of CP-violating asymmetries in channels such as $B_d \to \phi \pi^0$ or $K^0 \overline{K}{}^0$ would not necessarily require beyond-Standard-Model effects to explain them. The B_s decays $b \to c\overline{c}s$ and $b \to s\overline{s}s$ are not affected by this argument. In the first of these the tree terms dominate and the dominant penguin contributions have the same weak phase as those, so the doubly Cabibbo-suppressed sub-dominant penguin contributions are truly negligible. Even in the second case, where there are no tree contributions, the sub-dominant penguin terms are again doubly Cabibbo-suppressed $(V_{ub}V_{us}^*$ compared to $V_{cb}V_{cs}^*)$ and thus the possible Standard Model asymmetry is less than a few

There are some common decay channels of the B^0 and $\overline{B}{}^0$ which are not CP eigenstates. For example the channel $J/\psi(1S)K^*(892)$ where the $K^*(892) \to K_S\pi^0$, the final state is not a CP eigenstate because both even and odd relative angular momenta between the $J/\psi(1S)$ and the $K^*(892)$ are allowed. If there is sufficient data one can use angular analysis to separate the different CP final states and measure the asymmetry in each [21]. The same applies in many quasi-two-body decays, such as other vector-vector channels, or those with higher-spin particles in final states. The branching ratio to these channels can be significantly larger than the CP-eigenstate (vector-scalar or scalar-scalar) channels with the same quark content. Such angular analyses may therefore be important in achieving accurate values for the parameters α and β .

Additional ways to extract CKM parameters by relationships between rates for channels such as $\pi\pi$, πK that can be extracted using SU(3) invariance have received considerable recent attention in the literature. [20] While these relationships will be interesting to investigate, the uncertainties introduced by SU(3) corrections may be significant. The review by Buras cited above gives a good summary of these ideas.

Beyond-Standard-Model effects: The predictions given above are all for the Standard Model. Models beyond the Standard Model may introduce additional contributions to the mixing amplitudes and thereby destroy the relationships given here; in addition they may introduce further direct CP violation.

One model often used as a "straw man" in evaluating the potential of experimental tests of Standard Model predictions is the superweak model, which was one of the earliest proposals for the mechanism of CP violation; in fact it predates the

Standard Model [22]. In the modernized version of this model it is assumed that the CKM matrix is real and that all CPviolating effects arise from a contribution to the mixing that comes from beyond the Standard Model. In this case all the CP-eigenstate channels for B decay would have the same CPviolating asymmetry (up to a sign which differs for CP-odd and CP-even channels) [23]. This applies even to those channels predicted to have zero asymmetry in the Standard Model, as well as those for which the Standard Model prediction is complicated by the competition between tree and penguin contributions. Observation of significantly different asymmetries in any two neutral B decay CP-eigenstate channels would rule out such a model. In addition the observation of any asymmetry in a charged B decay or in a neutral B decay to a flavor-tagging final state would be evidence for direct CP violation [24] and would exclude the superweak model.

Many other models for the physics beyond the Standard Model have been discussed in the literature [25]. The most common additional CP-violating effect is a new contribution to the mixing process, due for example to charged Higgs contributions. The appearance of such contributions in K mixing is already severely restricted by the neutral-K mass difference. However this does not rule out additional contributions to B mixing that would destroy the relationship between the mixing phase ϕ_M and the CKM-matrix elements. This in turn would lead to violations of the predictions given in Table 1 which are based on this relationship. Models with additional (exotic or fourth generation) quarks would remove the constraints of the three-generation mixing matrix and hence lead to the failure of Eq. (9) and would allow new contributions to $B^0 - \overline{B}{}^0$ mixing and hence lead to the failure of Eq. (19) [26]. Any observed deviations from the relationships predicted by the Standard Model will provide a window on the nature of physics beyond the Standard Model.

While the discussion above stresses those channels in which there is a simple relationship between an observed asymmetry and the parameters of the CKM matrix in the Standard Model, this does not mean that other channels are entirely without interest. To date CP violation has only been observed in the neutral K system. Any observation of CP violation in B decays would be exciting. The Standard Model prediction is that direct *CP*-violating asymmetries are likely to be at most a few percent, so large effects in these channels would suggest beyond Standard Model effects. On the other hand, even within the Standard Model the asymmetries due to the interference between decays with and without mixing in the neutral B system can be quite large; current constraints do not rule out cases where Im $(r_{f_{CP}})$ is 1. It is likely that study of the many common decay channels of the B^0 and the \overline{B}^0 will greatly expand our understanding of the sources of CP violation.

B^{\pm}/B^{0} ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that B($\Upsilon(4S) \rightarrow B\overline{B}$) = 100%.

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possiblity would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more' definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the ${\it B}$ sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

 $\overline{\mathcal{B}}$ modes are charge conjugates of the modes below. Reactions indicate

	Mode	Fraction (Γ_i/Γ)	Confidence level

²⁰ ALBRECHT 94c find $\Gamma(b \rightarrow c)/\Gamma(b \rightarrow all) = 0.99 \pm 0.02 \pm 0.04$.

21 BARTELT 938 (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3-2.6 GeV/c which is attributed to $b \rightarrow u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{BB} between $(1.15\pm0.16\pm0.15)\times10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54\pm0.22\pm0.20)\times10^{-4}$

as evaluated using the KS model (NOEKNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-1}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008 , respectively. ²²ALBRECHT 91c result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \rightarrow u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3-2.6 GeV momentum range.

23 FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the 2.3-2.8 GeV momentum range. p=2.4-2.6 GeV signaling the presence of the $b\to u$ transition. The average branching ratio, $(1.8\pm0.4\pm0.3)\times10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}|=0.1$ using $B(b\to c\ell\nu)=10.2\pm0.2\pm0.7\%$.

24 ALBRECHT 90 observes 41 interval p = 2.3–2.6 GeV signorrespond to a model-deper 25 The quoted possible limits r model or momentum range calculated. using our best value. They also use the mark III $B(D^+ \to K^-\pi^+)$ braintining naction, 39 ALBRECHT 91H reports $0.348 \pm 0.060 \pm 0.035$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.55 \pm 0.04$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (68.3 \pm 1.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \to K^-\pi^+) = 0.0371 \pm 0.0025$.

⁴⁰BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \to K^-\pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. The product branching ratio for $B(B \to D^*(2010)^+)$ $B(D^*(2010)^+ \to D^0\pi^+)$ is 0.13 \pm 0.02 \pm 0.012. Superseded by BORTOLETTO 92.

 41 V – A momentum spectrum used to extrapolate below p=1 GeV. We correct the value assuming B($D^0\to K^-\pi^+$) = 0.042 ± 0.006 and B($D^{*+}\to D^0\pi^+$) = 0.6 $^{+0.08}_{-0.15}$. The product branching fraction is B($B\to D^{*+}$ X)·B($D^{*+}\to \pi^+D^0$)·B($D^0\to K^-\pi^+$) = (68 ± 15 ± 9) × 10 $^{-4}$.

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE MEAN LIFE

These measurements of the B mean life are averages over bottom particles produced, weighted by their semileptonic branching ratios, unless otherwise stated. Only the measurements at high energy are averaged since it is expected that the admixtures of b hadrons from Z decay and 1.8 TeV $\rho \, \overline{\rho}$ collisions should should not differ significantly.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the B^\pm Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

¹ Uses inclusively re	econstruct	ed secondary vertic	es.	

- Uses inclusively reconstructed secondary vertices.
 BUSKULIC 96F analyzed using 3D impact parameter.
- 3 ABE, K 95B uses an inclusive topological technique. ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E. 5 ABE 93J analyzed using $J/\psi(1S) \rightarrow \mu\mu$ vertices.
- ACTON 931 and ADRIANI 934 analyzed using lepton (e and μ) impact parameter at Z. 7 BUSKULIC 930 analyzed using dipole method.
- $^\prime$ BUSKULIC 930 analyzed using dipole method. 8 Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result. 9 From proper time distribution of $b \rightarrow J/\psi(15)$ anything. 10 ABREU 93D data analyzed using $D/D^*\ell$ anything event vertices. 11 ABREU 93C data analyzed using charged and neutral vertices.

- 12 ACTON 93c analysed using D/D^+ (anything event vertices.)
 13 ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0\pm 1.0\pm 0.8)\times$ $10^{-13}\,\mathrm{s}$ for an admixture weighted by production fraction and semileptonic branching
- $14\frac{\text{Taction.}}{\text{ACTON}}$ 92 is combined result of muon and electron impact parameter analyses. 15 BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991
- 16 Fun.

 16 BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored hadrons are in the same ratio.

 17 hadrons are in the same ratio.

 18 listing $2\pi \to e^+ X$ or $\mu^+ X$, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
- of B nations from the impact parameter distribution of the exponential B using $Z \to J/\psi(1S)X, J/\psi(1S) \to \ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.
- 21 LYONS 90 combine the results of the B lifetime measuresments of ONG 89, BRAUN-SCHWEIG 898, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life. and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.

 22 We have combined an overall scale error of 15% in quadrature with the systematic error
- of \pm 0.7 to obtain \pm 2.1 systematic error. ²³ Statistical and systematic errors were combined by BROM 87.

b PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $Sp\overline{p}S$) are used in the branching fraction averages. The production fractions give our best current estimate of the admixture at

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibilty would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

The modes below are listed for a \overline{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include

Mode Fraction (Γ_i/Γ)

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at the Z have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by O. Hayes (CERN) and M. Jimack (U. Birmingham) as described in the note "Production and Decay of b-Flavored Hadrons" in the B^\pm Particle Listings. Values assume

$$\begin{array}{ll} B(\overline{b} \to B^+) = B(\overline{b} \to B^0) \\ B(\overline{b} \to B^+) + B(\overline{b} \to B^0) + B(\overline{b} \to B^0_S) + B(b \to \Lambda_b) = 100 \text{ \%}. \end{array}$$

The notation for production fractions varies in the literature (f_{B^0}, f(b \rightarrow $\overline{B}{}^0$), Br($b \to \overline{B}{}^0$)). We use our own branching fraction notation here, $B(\overline{b} \rightarrow B^0).$

	$\overline{\underline{b}} \rightarrow B^+$	(37.8 ± 2.2) %
Γ_2	$\overline{b} \rightarrow B^0$	(37.8 ± 2.2) %
Γ3	$\overline{b} \rightarrow B_s^0$	(11.2 + 1.8 - 1.9)%
Ги	$b \rightarrow \Lambda_b$	(132 + 41)%

- 27 ABREU 95D give systematic errors ± 0.0019 (model) and 0.0012 (R_{c}). We combine
- these in quadrature. 28 BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton ρ and $\rho_{\mathcal{T}}$ (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high $\rho_{\mathcal{T}}$, but the lower $\rho_{\mathcal{T}}$ portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ± 0.0026 and is included in the systematic error.

$\Gamma(e^+\nu_e \text{ anything})/\Gamma_{\text{total}}$

These branching fraction values are model dependent. See the note on "Semileptonic Decays of D and B Mesons, Part II" at the beginning of the B^+ Particle Listings.

 $^{^3}$ Measured using $D_s^-\ell^+$ vertices.

BO DECAY MODES

These branching fractions all scale with $B(\overline{b} \rightarrow B_s^0)$, the LEP B_s^0 production fraction. The first four were evaluated using $B(\overline{b} \rightarrow B_S^0) =$ $(11.2 + 1.8 \atop -1.9)\%$ and the rest assume B($\overline{b} \rightarrow B_5^0$) = 12%.

The branching fraction B($B_s^0 o D_s^- \ell^+
u_\ell$ anything) is not a pure measurement since the measured product branching fraction $B(\overline{b} \rightarrow B_s^0) \times$ ${\sf B}(B_s^0 \to D_s^-\ell^+\nu_\ell$ anything) was used to determine ${\sf B}(\overline{b} \to B_s^0)$, as described in the note on "Production and Decay of *b*-Flavored Hadrons."

	Mode	Fraction (Γ_i/Γ_i)	-) Con	fidence level
Γ_1	D_s^- anything	(87 ±31) %	
Γ_2	$D_s^-\ell^+ u_\ell$ anything	[a] (7.6 ± 2.	4) %	
Γ_3	$D_s^- \pi^+$	< 12	%	
Γ_4	$J/\psi(1S)\phi$	< 6	\times 10 ⁻³

Γ_{11}	$\gamma\gamma$ B1	< 1.48	× 10 ⁻⁴	90%

[a] Not a pure measurement. See note at head of B_s^0 Decay Modes.

BO BRANCHING RATIOS

 $\Gamma(D_s^- \text{ anything})/\Gamma_{\text{total}}$ Γ_1/Γ

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.87±0.31 OUR AVE	RAGE			
$0.76 \pm 0.23 \pm 0.23$	90	¹⁰ BUSKULIC	96E ALEP	$e^+e^- o Z$
$1.46 \pm 0.54 \pm 0.44$	147	¹¹ ACTON	92N OPAL	$e^+e^- \rightarrow Z$

¹⁰ BUSKULIC 96E separate $c\bar{c}$ and $b\bar{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\overline{b} \to W^+ \to D_s^+$ events, and obtain $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^-$ anything) = 0.088 ± 0.020 ± 0.020 assuming B($D_S \rightarrow \phi \pi$) = (3.5 ± 0.4) × 10⁻² and PDG 1994 values for the relative partial widths to other D_S channels. We evaluate using our current values B($\overline{b} \to B_S^0$) = 0.112 $^{+0.018}_{-0.019}$ and B($D_S \to \phi \pi$) = 0.036 \pm 0.009. Our first error is their experiment's and our second error is that due to B($\overline{b} \to B_S^0$) and B($D_S \to \phi \pi$).

 11 ACTON 92N assume that excess of 147 \pm 48 D_S^0 events over that expected from B^0 , B^+ , and $c\overline{c}$ is all from B_s^0 decay. The product branching fraction is measured to be $\mathsf{B}(\overline{b}\to \ B_s^0)\mathsf{B}(B_s^0\to \ D_s^- \text{ anything})\times \mathsf{B}(D_s^-\to \ \phi\pi^-) = (5.9\pm 1.9\pm 1.1)\times 10^{-3}.$ We evaluate using our current values $B(\overline{b}\to B_S^0)=0.112^{+0.018}_{-0.019}$ and $B(D_S\to\phi\pi)=0.036\pm0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_S^0)$ and $B(D_S \to \phi \pi)$.

 $\Gamma(D_s^-\ell^+\nu_\ell \text{anything})/\Gamma_{\text{total}}$ The values and averages in this section serve only to show what values result if one assumes our $B(\bar{b} \to B_s^0)$. They cannot be thought of as measurements since the

underlying product branching fractions were also used to determinine $B(\overline{b}\to B_s^0)$ as described in the note on "Production and Decay of b-Flavored Hadrons."

	VALUE	EV15	DOCUMENT ID		COMMENI		
	0.076±0.024 OUR AVE	RAGE

	12 0 1 10 1 1 1 1 0 0 0 0 0					5/7	

 12 BUSKULIC 950 use $D_{_{f S}}\ell$ correlations. The measured product branching ratio is B(\overline{b} ightarrow B_s) × B($B_s \rightarrow D_s^- \ell^+ \nu_\ell$ anything) = (0.82 \pm 0.09 $^+$ 0.13)% assuming B($D_s \rightarrow \phi \pi$) = (3.5 \pm 0.4) × 10 $^-$ 2 and PDG 1994 values for the relative partial widths to the six other D_s channels used in this analysis. Combined with results from $\Upsilon(4S)$ experiments this can be used to extract B($\overline{E}_s \rightarrow D_s$) (10.0 \pm 0.2 \pm 2.5 \pm 3.5 his can be used to extract B($\overline{b} \rightarrow B_S$) = (11.0 \pm 1.2 $^{+2.5}_{-2.6}$)%. We evaluate using our current values B($\overline{b} \to B_S^0$) = 0.112 $^{+0.018}_{-0.019}$ and B($D_S \to \phi\pi$) = 0.036 \pm 0.009. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and

 13 ABREU 92M measured muons only and obtained product branching ratio B(Z
ightarrow bor $\overline{b}) \times \mathsf{B}(\overline{b} \to B_{\mathsf{S}}) \times \mathsf{B}(B_{\mathsf{S}} \to D_{\mathsf{S}} \mu^+ \nu_{\mu} \, \mathsf{anything}) \times \mathsf{B}(D_{\mathsf{S}} \to \phi \pi) = (18 \pm 8) \times 10^{-5}.$ We evaluate using our current values $B(\overline{b} \to B_S^0) = 0.112 {+0.018 \atop -0.019}$ and $B(D_S \to \phi\pi)$ = 0.036 ± 0.009. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_S^0)$ and $B(D_S \to \phi\pi)$. We use $B(Z \to bor \overline{b}) = 2B(Z \to b\overline{b}) = 2B(Z \to b\overline{b})$ $2\times(0.1546\pm0.0014)$.

^{*}Measured using D_S to retrices.

5 Measured using $\phi \ell$ vertices.

5 Measured using $\phi \ell$ vertices.

6 Measured using inclusive D_S vertices.

7 Exclusive reconstruction of $B_S \rightarrow \psi \phi$.

8 Combined result for the four ABREU 96F methods.

9 ABREU 94E uses the flight-distance distribution of D_S vertices, ϕ -lepton vertices, and D_{-H} vertices. $D_{S}\mu$ vertices.

 $^{26}\, \rm BUSKULIC$ 95J is their $\Delta m_{B_{\varsigma}^0}$ measurement combined with $\tau_{B_{\varsigma}^0}=1.61\, \rm ps,~our~central$ value. Assumes $f_S = 11.2\%$.

value. Assumes 15 = 11.27.

27 From a combination of DELPHI (ABREU 94F), CLEO (ARTUSO 89), and ARGUS (ALBRECHT 92L). Estimated from ABREU 94F figure 7.

(ALBRECHT 921). Estimated from ABREU 94F figure 7.
28 Uses BARTELT 93 to remove B_d mixing contribution and assuming $f_d=0.375\pm0.05$ and $f_s=0.15\pm0.05$.
29 From combination of L3 (ADEVA 92C), CLEO (ARTUSO 89), and ARGUS (ALBRECHT 921). Corresponding limit is >0.16 at 90%CL.
30 From combination of UA1 (ALBAJAR 910), CLEO (BEAN 87B), ARGUS (ALBRECHT 87I), ALEPH (DECAMP 91), and L3 (ADEVA 90P). Corresponding limits are >0.23 at 95% CL and >0.27 at 90% CL.

χ_{B} at high energy

This is a B- \bar{B} mixing measurement for an admixture of B^0 and B^0_s at high energy, $\chi_B=f_d\chi_d+f_s\chi_s$

 $^{\chi}B=^{I}d^{\chi}d+^{I}s^{\Lambda}s$ where f_d and f_s are the production fractions of B_d^0 and B_s^0 mesons relative to all b-flavored hadrons. Only the measurements at the Z and higher energy $p\bar{p}$ are averaged. TECN COMMENT $\begin{array}{c|c} \underline{\textit{VALUE}} & \underline{\textit{CL\%}} & \underline{\textit{EVTS}} \\ \hline \textbf{0.126} \!\pm\! 0.008 \ \textbf{OUR AVERAGE} \end{array}$ DOCUMENT ID

45,48 SCHAAD 31 This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes

85 MRK2 $E_{\rm cm}^{ee} = 29 \, {\rm GeV}$

0.004 for model dependence. ³² BUSKULIC 94G data analyzed using $e\,e,\,e\,\mu$, and $\mu\mu$ events.

90

33 AKERs 938 analysis performed using ete, e.μ., and μμ events.

34 BUSKULIC 94g data analysis performed using dilepton events.

35 ABE 91G measurement of X is done with e.μ and ee events.

36 ALBAJAR 91D measurement of X is done with dimuons.

37 ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for X̄ = f_QX_Q+0.9f_XX_S.

38 This ABREU 94 result combines $\ell\ell$, $\Lambda\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\overline{X} = f_d X_d + 0.96 f_s X_s$.

40 ABREU 93c data analyzed using $e\,e,\,e\,\mu$, and $\mu\mu$ events. 41 ACTON 92c uses electrons and muons. Superseded by AKERS 93B.

 42 ADEVA 92c uses electrons and muons. 43 DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B. 44 ADEVA 90P measurement uses $ee,~\mu\mu,~$ and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92c.

Superseded by ADEVA 92c. 45 These experiments are not in the average because the combination of B_S and B_d mesons which they see could differ from those at higher energy. 46 The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38. 47 ALBAJAR 87c measured $X=(\overline{B}^0\to B^0\to \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV. 48 Limit is average probability for hadron containing B quark to produce a positive lepton.

$$\begin{split} \Delta m_{B_s^0} &= m_{B_{sH}^0} - m_{B_{sL}^0} \\ & \Delta m_{B_s^0} \text{ is a measure of the } B_s^0 \text{-} \overline{B}_s^0 \text{ oscillation frequency in time-dependent mixing} \end{split}$$

 $^{49}\, {\rm BUSKULIC}$ 95J determine $\Delta m_{B_{-}^0}$ from time dependence of B mixing using a jet charge technique to tag initial quark state and a lepton tag to determine flavor of the decaying b quark. They find $\Delta m_g > 5.6$ [> 6.1] \hbar ps⁻¹ when $f_s = 10\%$ [12%]. We interpolate to our central value $f_s = 11.2\%$. 50 Uses dileptons.

$x_s = \Delta m_{B_c^0} / \Gamma_{B_s^0}$

This section combines the results from the previous two sections.

Time integrated mixing measurement of X determine this quantity directly via

$$\frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = \left(\frac{\chi}{0.5 - \chi}\right)^{1/2}$$

while time-dependent mixing measurements determine $\Delta m_{B_{\S}^0} = m_{B_{\S L}^0} - m_{B_{\S L}^0}$ which

$$\frac{\Delta m_{B_s^0}}{\Gamma_{B^0}} = \frac{(m_{B_s^0 H}^0 - m_{B_{sL}^0}) \ \tau_{B_s^0}}{\hbar}$$

THE CHARMONIUM SYSTEM

The current state of knowledge of the charmonium system and transitions, as interpreted by the charmonium model. Uncertain states and transitions are indicated by dashed lines. The notation γ^* refers to decay processes involving intermediate virtual photons, including decays to e^+e^- and $\mu^+\mu^-$.

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 13 measurements and one constraint to determine 6 parameters. The overall fit has a χ^2 = $6.9 \ \text{for 8 degrees of freedom}\,.$

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

BRANDELIK 79C DASP e+e-

This combination of a partial width with the partial width into e^+e^- and with the total width is obtained from the integrated cross section into channel $_{\rm l}$ in the e^+e^- annihilation. We list only data that have not been used to determine the partial width $\Gamma({\rm l})$ or the branching ratio $\Gamma({\rm l})/{\rm total}.$

WIDTH DETERMINATIONS OF THE Υ STATES

As is the case for the $J/\psi(1S)$ and $\psi(2S)$, the full widths of the $b\overline{b}$ states $\Upsilon(1S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ are not directly measurable, since they are much narrower than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \ , \tag{1}$$

where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction ($\ell=e, \mu, \text{ or } \tau$). One then assumes e- μ - τ universality and uses

$$\Gamma_{\ell\ell} = \Gamma_{ee}$$

$$B_{\ell\ell} = \text{average of } B_{ee}, \ B_{\mu\mu}, \ \text{and } B_{\tau\tau} \ .$$
 (2)

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only in the combination $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$, where $\Gamma_{\rm had}$ is the hadronic partial width and

$$\Gamma_{\text{had}} + 3\Gamma_{ee} = \Gamma \ . \tag{3}$$

This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\int \sigma(e^+e^- \to \Upsilon \to \text{hadrons})dE$$

resonanc

$$=\frac{6\pi^2}{M^2}\frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma}C_r = \frac{6\pi^2}{M^2}\frac{\Gamma_{ee}^{(0)}\Gamma_{\rm had}}{\Gamma}C_r^{(0)} , \qquad (4)$$

where M is the Υ mass, and C_r and $C_r^{(0)}$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1), and contains corrections from all orders of QED for describing $(b\bar{b}) \to e^+e^-$. The lowest order QED value $\Gamma_{ee}^{(0)}$, relevant for comparison with potential-model calculations, is defined by the lowest order QED graph (Born term) alone, and is about 7% lower than Γ_{ee} .

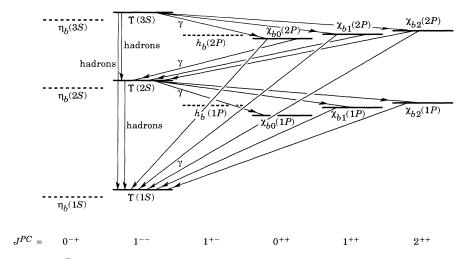

THE BOTTOMONIUM SYSTEM

Υ (11020)

Υ (10860)

 $\Upsilon(4S)$

 $B\overline{B}$ threshold

The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b , triplet states Υ and χ_{bJ} . In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. E.g., $h_b(2P)$ means 2^1P_1 with n=2, L=1, S=0, J=1, PC=+-. If found, D-wave states would be called $\eta_b(nD)$ and $\Upsilon_J(nD)$, with J=1,2,3 and $n=1,2,3,4,\cdots$. For the χ_b states, the spins of only the $\chi_{b2}(1P)$ and $\chi_{b1}(1P)$ have been experimentally established. The spins of the other χ_b are given as the preferred values, based on the quarkonium models. The figure also shows the observed hadronic and radiative transitions.

Bottomonium, $\Upsilon(1S)$

The Listings give experimental results on B_{ee} , $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$. The entries of the last quantity have been re-evaluated consistently using the correction procedure of KURAEV 85.The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{had}}{\Gamma(1 - 3B_{\ell\ell})} \ . \tag{5}$$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1).

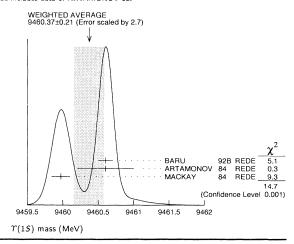

$$I^{G}(J^{PC}) = 0^{-}(1^{-})$$

Meson Particle Listings Non- $q\overline{q}$ Candidates

NON-qq CANDIDATES

We include here mini-reviews and reference lists on gluonium and other non- $q\overline{q}$ candidates. See also $N\overline{N}(1100\text{--}3600)$ for possible bound states.

$NON-q\overline{q}$ MESONS

The existence of gluon self coupling in QCD suggests that gluonia (or glueballs) and hybrids $(q\overline{q}g)$ might exist. Another possible kind of non- $q\overline{q}$ mesons is multiquark states. For detailed reviews, see HEUSCH 86, CLOSE 87, TOKI 88, and BURNETT 90. Among the signatures naively expected for glueballs are (i) no place in $q\overline{q}$ nonets, (ii) flavor-singlet couplings, (iii) enhanced production in gluon-rich channels such as $J/\psi(1S)$ decay, and (iv) reduced $\gamma\gamma$ coupling. However, mixing effects with $q\overline{q}$ states, and other dynamical effects such as form factors, may obscure these simple signatures. If mixing is large, only the finding of more states than are predicted by the $q\overline{q}$ quark model remains as a clear signal for non-exotic non- $q\overline{q}$ states.

Lattice gauge theory calculations in the quenched approximation (without quark loops) predict the lightest glueball to be a scalar with a mass of typically 1550 ± 95 MeV (BALI 93). The same calculations find a tensor glueball mass of 2270 ± 100 MeV, and glueballs with other spin-parities are predicted to be still heavier. A more recent lattice calculation (SEXTON 95) predicts a slightly higher mass, 1740 ± 71 MeV. Including dynamical quarks will, however, change the predicted masses.

Hybrid mesons are $q\overline{q}$ states combined with a gluonic excitation (BARNES 82, CHANOWITZ 83, ISGUR 85, CLOSE 95). Hybrids span flavor nonets, may have exotic (non- $q\overline{q}$) quantum numbers (a $J^{PC}=1^{-+}$ state is expected in all models), and are predicted to have characteristic decay modes (LEYAOUANC 85, CLOSE 95). The masses of the lightest hybrids are typically predicted to be in the range 1500 to 2000 MeV. Charm hybrids ($c\overline{c}g$) are attractive experimentally since they may appear as supernumerary states in the predictable charmonium spectrum. The $\psi(4040)$ and $\psi(4160)$ are possibly mixtures of $c\overline{c}$ and $c\overline{c}g$ states (CLOSE 96).

The third class of non- $q\bar{q}$ states, the multiquark states, can be either baglike or clusters of mesons (VOLOSHIN 76, JAFFE 77, GUTBROD 79). A subclass of the latter are the deuteronlike meson-meson bound states, or deusons, where the long-range pion exchange is the major source of binding (TORNQVIST 91 and 94, ERICSON 93, MANOHAR 93). Many of the best non- $q\overline{q}$ candidates discussed below lie close to important thresholds, which suggests that they might be bound states of a meson pair. Examples include the $f_0(980)$ and $a_0(980)$ (close to the $K\overline{K}$ threshold), the $f_1(1420)$ (above the $K\overline{K}^*$ threshold, thus not a bound state but perhaps a threshold enhancement), the $f_0(1500)$ and $f_2(1520)$ ($\omega\omega$ and $\rho\rho$), the $f_J(1710)$ $(K^*\overline{K}^*)$, and the $\psi(4040)$ $(D^*\overline{D}^*)$. Many suggestions for such mesonium candidates, involving both light and heavy quarks and binding mechanisms, have appeared (WEINSTEIN 90, DOVER 91, BARNES 92, DOOLEY 92).

The candidates we discuss below are chosen because they are difficult to interpret as conventional $q\overline{q}$ states. We do not see it as our task to discuss theoretical interpretations of the candidates, but merely to catalogue the observations of possible relevance.

Scalar mesons: There are four known isoscalars with $J^{PC}=0^{++}$: the $f_0(400-1200)$, a very broad structure around 800 MeV, the $f_0(980)$, the $f_0(1370)$, and the $f_0(1500)$; the spin of another established isoscalar, the $f_J(1710)$, may be 0 or 2. In the quark model, one expects two 1^3P_0 states and one $2^3P_0(u\overline{u}+d\overline{d})$ -like state below 1.8 GeV. Thus, there are too many scalars to find a place in the quark model.

However, for scalar resonances, naive quark model expectations, in particular ideal mixing, could be strongly broken by the opening of inelastic thresholds. Thus, the physical scalar $q\bar{q}$ spectrum may be very much distorted from naive expectations. For a detailed discussion of this sector, see our Note under the $f_0(1370)$.

In this edition, we have merged the $f_0(1590)$ observed in π^-p interactions at high energies with the $f_0(1525)$ observed in $\overline{p}p$ annihilations, under the new name $f_0(1500)$. The $\pi\pi$ and $\eta\eta$ S-waves have a T-matrix pole at $m-i\Gamma/2\sim 1500-i60$ MeV, which corresponds to the physical mass and width (AMSLER 95B, AMSLER 95C), while a simple Breit-Wigner description gives a slightly higher mass and width (AMSLER 92, ALDE 88). For consistency, we average the mass and width determined by the T-matrix poles. A coupled-channel analysis taking unitarity constraints into account has been performed in $\overline{p}p$ (AMSLER 95D) but not in π^-p . Thus, we do not view the apparent discrepancies in the decay branching ratios to $\pi^0\pi^0$, $\eta\eta$, and $\eta\eta'$ between the $\overline{p}p$ and π^-p experiments to be serious.

In the model of $\Lambda MSLER$ 95E and $\Lambda MSLER$ 96, the (nearly ideally mixed) ground state scalar $q\overline{q}$ nonet consists of the $a_0(1450)$, the $K_0^*(1430)$, the $f_0(1370)$, and the still missing isoscalar $s\overline{s}$ state, which cannot be the $f_0(1500)$ due to its comparatively narrow width and low $K\overline{K}$ decay branching ratio. The $f_0(1500)$ is interpreted as a scalar glueball mixed with the two nearby $q\overline{q}$ isoscalars.

The $f_J(1710)$ (whose spin is uncertain) has been seen mainly in the gluon-rich $J/\psi(1S)$ radiative decay, where it is copiously produced. Before 1991, the spin of the $f_J(1710)$ was believed to be 2, and the subsequent spin-0 determination in $J/\psi(1S)$ radiative decay (CHEN 91) has not been confirmed. In central production, the WA76 experiment (ARMSTRONG 89D) on 300 GeV/c pp interactions sees a structure at the same mass, but favors spin 2. The $f_J(1710)$ has not been seen in hadronic production $(K^-p\to K\overline{K}A)$ (ASTON 88D), nor in $\gamma\gamma$ fusion. The ratio of the branching fractions in $J/\psi(1S)\to \omega f_J$ and $J/\psi(1S)\to \phi f_J$ suggests that nonstrange and strange components are both important in this state. Its mass and width are consistent with the prediction for the ground-state glueball, according to the most recent lattice gauge calculations (SEXTON 95), if one assumes that the spin is indeed zero.

Meson Particle Listings Non- $q\bar{q}$ Candidates

Pseudoscalar mesons: The established isoscalars with $J^{PC} = 0^{-+}$ are the η , the $\eta'(958)$, the $\eta(1295)$, and the $\eta(1440)$ [which may be two pseudoscalar resonances, an $\eta(1410)$ and an $\eta(1490)$; see the Note under the $\eta(1440)$]. In the $q\bar{q}$ model, one expects two 1^1S_0 and two 2^1S_0 pseudoscalars between 500 and

Identifying the $\eta(1280)$ with the 2^1S_0 $(u\overline{u}+d\overline{d})$ state is natural, but it is more problematic to identify one of the two peaks in the $\eta(1440)$ region with the 2^1S_0 $s\overline{s}$ state. The $\eta(1440)$ is observed in $s\overline{s}$ -depleted reactions like $\pi^-p \to \eta\pi\pi n$ (ANDO 86), $p\overline{p}$ annihilation (BAILLON 67, AMSLER 95F, BERTIN 95), and $\pi^-p \to a_0(980)\pi p$ (CHUNG 85, BIRMAN 88), and is not seen in the $s\overline{s}$ -enriched channels like $K^-p \to K^*(892)\overline{K}A$ (ASTON 87). The fact that ANDO 86 sees the $\eta(1440)$ and $\eta(1280)$ with similar intensities argues that these states are of a similar nature, e.g., radial excitations of the η and $\eta'(958)$. However, as there are suggestions that the $\eta(1440)$ is in fact two η 's, the situation remains confused.

The $\pi(1770)$ (BERDNIKOV 94, AMELIN 95B) has a surprisingly narrow width (if interpreted as the second radial excitation of the π), a large coupling to $K\overline{K}$, and decays to a pair of mesons, one with $\ell(q\overline{q}) = 0$, the other with $\ell(q\overline{q}) = 1$. This is the signature expected for a hybrid meson (CLOSE 95).

Axial-vector mesons: The $q\overline{q}$ model predicts a nonet that includes two isoscalar 1^3P_1 states with masses below about 1.6 GeV. Three such 1^{++} states are known, the $f_1(1285)$, the $f_1(1420)$, and the $f_1(1530)$, which suggests that one of these is a non- $q\overline{q}$ meson. The $f_1(1420)$ is the most likely candidate: see CALDWELL 90 and the Note under the $f_1(1420)$. The proximity of the $K\overline{K}^*$ threshold suggests this may be a dominantly $K\overline{K}^*$ mesonium resonance or a threshold enhancement (LONGACRE 90, TORNOVIST 91).

Tensor mesons: The two $1^{3}P_{2}$ $q\overline{q}$ states are very likely the well-known $f_{2}(1270)$ and $f'_{2}(1525)$. There are several other states, which have been suggested as $J^{PC} = 2^{++}$ non- $q\overline{q}$ candidates: the $f_{2}(1430)$, $f_{2}(1520)$, $f_{J}(1710)$, $f_{2}(1810)$, $f_{2}(2010)$, $f_{2}(2150)$, $f_{2}(2300)$, and $f_{2}(2340)$.

The $f_2(1520)$ is observed by the ASTERIX Collaboration (MAY 89) in $p\overline{p}$ P-wave annihilation in the $\pi^+\pi^-\pi^0$ channel and by the Crystal Barrel Collaboration (ANISOVICH 94, AMSLER 95B) in $3\pi^0$, close to the $\rho\rho$ and $\omega\omega$ thresholds. It has no place in a $q\overline{q}$ scheme, since all nearby $q\overline{q}$ states are already accounted for. Similarly, the $f_J(1710)$ could be composed of $K^*\overline{K}^*$ and $\omega\phi$ (DOOLEY 92), since it lies close to these thresholds.

Of the heavier states, the $f_2(1810)$ is likely to be the 2^3P_2 , and among those above 2 GeV one expects the 2^3P_2 $s\bar{s}$, 1^3F_2 $s\bar{s}$, and 3^2P_2 $s\bar{s}$, but a gluonium interpretation of one of the four states is not excluded. These three f_2 resonances have been observed in the OZI-rule forbidden process $\pi p \to \phi \phi n$ (ETKIN 88), which has been claimed as favoring the gluonium interpretation.

A similar $\phi\phi$ mass spectrum is seen by ARMSTRONG 89B in the \varOmega spectrometer. The DM2 and MARK-III collaborations see threshold $\phi\phi$ production, but favor $J^P=0^-$, not $_{2}^+$

In $\gamma\gamma\to 4\pi$ near the $\rho\rho$ threshold, TASSO (BRANDE-LIK 80B, ALTHOFF 82), MARK2 (BURKE 81), CELLO (BEHREND 84E), PLUTO (BERGER 88B), SLAC TPC (AIHARA 88), and ARGUS (ALBRECHT 91F) observe a resonance-like structure. This is dominated by $\rho^0\rho^0$, and the cross section peaks a little above the $f_2(1520)$. This process has not been explained by models in which only conventional resonances dominate. The fact that the $\gamma\gamma\to\rho^+\rho^-$ is small (ALBRECHT 91F quotes 1/4 for the $\rho^+\rho^-/\rho^0\rho^0$ ratio) requires both isospin 0 and 2 for the $\rho\rho$ system. A resonance interpretation in terms of $q^2\bar{q}^2$ states thus requires the presence of a flavor exotic I=2 resonance (ACHASOV 82, 87, 90). The 2++ partial wave is found to dominate the $\rho\rho$ structure (BERGER 88B, ALBRECHT 91F), with some 0++ at the lowenergy end, while $J^P=0^-$ and 2- contribute very little.

In $\gamma\gamma \to \omega\rho$ and $\phi\rho$, there are also broad enhancements that peak near 1.7 GeV. The dominant partial wave is 2^{++} in $\omega\rho$, while 2^{-+} is favored in $\phi\rho$ (ALBRECHT 94Z).

Other exotic or non- $q\overline{q}$ candidates: An isovector $\phi\pi^0$ resonance at 1480 MeV has been reported by BITYUKOV 87 in $\pi^-p \to \phi\pi^0n$ (listed under the $\rho(1450)$). Preliminary indications favor the nonexotic $J^{PC}=1^{--}$, but the large OZI-rule violating branching ratio $\phi\pi:\omega\pi$ seems peculiar for a $(u\overline{u}-d\overline{d})$ I=1 $q\overline{q}$ object. However, ACHASOV 88 shows that the threshold effect from the two-step process $\rho(1600) \to K\overline{K}^* \to \pi\phi$ can violate the rule, especially near threshold. No sign of this candidate is seen in $\pi\omega$ (FUKUI 91). In addition, the small coupling to the photon makes an identification with the $\rho(1450)$ difficult (CLEGG 88). More recently DONNACHIE 93, analyzing e^+e^- -annihilation and diffractive-photoproduction data, suggests there may be 4-quark states near 1100 and 1300 MeV.

Another exotic candidate is the $\hat{\rho}(1405)$ (ALDE 88B, IDDIR 88), seen in the GAMS experiment under the $a_2(1320)$ in $\pi^-p \to \eta \pi^0 n$ with the exotic quantum numbers $J^{PC} = 1^{-+}$. The analysis of ALDE 88B has, however, been questioned by PROKOSHKIN 95B, 95C. Although the forward-backward asymmetry demands an $\eta \pi$ P-wave, it may be due to a nonresonant amplitude. The Crystal Barrel Collaboration has reported results on the corresponding P-wave in $\eta \pi$ seen in $p\bar{p} \to \eta \pi \pi$; they see a much broader effect, which can be explained as nonresonant or as a resonance with $\Gamma \approx 600$ MeV (AMSLER 94D). AOYAGI 93 also notes the $\eta \pi$ P-wave, but its interpretation is unclear

Another possible 1⁻⁺ candidate is the isosinglet X(1910) (ALDE 89), which seems to decay to $\eta\eta'$ but not to $\pi^0\pi^0$ or $\eta\eta$ (ALDE 89). An enhancement with quantum numbers 1⁻⁺, decaying to $f_1(1285)$, has also been reported around 1900 MeV (LEE 94).

Meson Particle Listings Non- $q\overline{q}$ Candidates

A narrow resonance, listed under the $K_J(3100)$, has been reported at about 3100 MeV (BOURQUIN 86, ALEEV 93) in several $A\overline{p}$ +pions and $\overline{A}p$ +pions states. The observation of the doubly-charged states $A\overline{p}\pi^-$ and $\overline{A}p\pi^+$ implies, assuming the decay is strong, I=3/2, clearly not a $q\overline{q}$ state. In addition, a narrow peak is observed at about 3250 MeV, listed under the X(3250), in the hidden strangeness combinations containing a baryon-antibaryon pair (ALEEV 93). However, all these observations need confirmation.

Non- $q\overline{q}$ Candidates

\bar{p}/p CHARGE-TO-MASS RATIO, $\left|\frac{q_{\bar{p}}}{m_{\bar{p}}}\right|/\left(\frac{q_{\bar{p}}}{m_{\bar{p}}}\right)$

A test of CPT invariance. Listed here are measurements involving the inertial masses. For a discussion of what may be inferred about the ratio of \overline{p} and p gravitational masses, see ERICSON 90; they obtain an upper bound of 10^{-6} – 10^{-7} for violation of the equivalence principle for \overline{p} 's.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

#### n MASS

The mass is known much more precisely in u (atomic mass units) than in MeV; see the footnotes. The conversion from u to MeV, 1 u =931.49432±0.00028 MeV, involves the relatively poorly known electronic charge. The DIFILIPPO 94 value, in u, is by far the best, but when converted to MeV differs only negligibly from the 1986 CODATA value, which, for consistency, we stick with.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
939.56563±0.00028	1 COHEN	87	RVUE	1986 CODATA value
• • • We do not use the fol	lowing data for average	s, fit	s, limits,	etc. • • •
$939.56565 \pm 0.00028$	² DIFILIPPO	94		Penning trap
$939.56564 \pm 0.00028$	3,4 GREENE	86	SPEC	$np \rightarrow d\gamma$
939.5731 ±0.0027	⁴ COHEN	73	RVUE	1973 CODATA value

- 1  The mass is known much more precisely in u:  $m=1.008664904\pm0.000000014$  u.
- The mass is known much more precisely in u:  $m=1.0086649235\pm0.000000023$  u. We use the conversion factor given above to get the mass in MeV.
- 3 The mass is known much more precisely in u:  $m=1.008664919\pm0.000000014$  u.  4  These determinations are not independent of the  $m_n-m_p$  measurements below.

#### 77 MASS

#### LIMIT ON NT OSCILLATIONS

#### Mean Time for $n\overline{n}$ Transition in Vacuum

A test of  $\Delta B{=}2$  baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 80 discuss the theoretical motivations for looking for  $n\overline{n}$  oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, and ALBERICO 91 for discussions. Direct searches for  $n \rightarrow \overline{n}$  transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table.

#### NOTE ON BARYON DECAY PARAMETERS

(by E.D. Commins, University of California, Berkeley)

#### Baryon semileptonic decays

ı

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\overline{B}_f \left[ f_1(q^2) \gamma_\lambda + i \ f_2(q^2) \sigma_{\lambda\mu} q^\mu + g_1(q^2) \gamma_\lambda \gamma_5 + g_3(q^2) \gamma_5 q_\lambda \right] B_i .$$

Here  $B_i$  and  $\overline{B}_f$  are spinors describing the initial and final baryons, and  $q=p_i-p_f$ , while the terms in  $f_1$ ,  $f_2$ ,  $g_1$ , and  $g_3$  account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer,  $f_1$  reduces to the vector coupling constant  $g_V$ , and  $g_1$  reduces to the axial-vector coupling constant  $g_A$ . The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The  $g_3$  term is negligible for transitions in which an  $e^\pm$  is emitted, and gives a very small correction, which can be estimated by PCAC [4], for  $\mu^\pm$  modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f}$$

where  $m_i$  and  $m_f$  are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher  $q^2$ , it is necessary to modify the form factors at  $q^2 = 0$  by a "dipole"  $q^2$  dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio  $g_A/g_V$  may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}$$
.

n

The presence of a "triple correlation" term in the transition probability, proportional to  $\text{Im}(g_A/g_V)$  and of the form

$$\boldsymbol{\sigma}_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu)$$

for initial baryon polarization or

$$\sigma_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle  $\phi$  has been measured precisely only in neutron decay (and in ¹⁹Ne nuclear beta decay), and the results are consistent with T invariance.

#### Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_{\pi}^2 \cdot \overline{B}_f (A - B\gamma_5) B_i ,$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma \widehat{\omega}_f \cdot \widehat{\omega}_i + (1 - \gamma)(\widehat{\omega}_f \cdot \widehat{\mathbf{n}})(\widehat{\omega}_i \cdot \widehat{\mathbf{n}}) + \alpha(\widehat{\omega}_f \cdot \widehat{\mathbf{n}} + \widehat{\omega}_i \cdot \widehat{\mathbf{n}}) + \beta \widehat{\mathbf{n}} \cdot (\widehat{\omega}_f \times \widehat{\omega}_i) ,$$

where  $\widehat{\mathbf{n}}$  is a unit vector in the direction of the final baryon momentum, and  $\widehat{\boldsymbol{\omega}}_i$  and  $\widehat{\boldsymbol{\omega}}_f$  are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  are defined as

$$\begin{split} \alpha &= 2\operatorname{Re}(s^*p)/(\,|\,s\,|^2 + \,|\,p\,|^2) \ , \\ \beta &= 2\operatorname{Im}(s^*p)/(\,|\,s\,|^2 + \,|\,p\,|^2) \ , \\ \gamma &= (\,|\,s\,|^2 - \,|\,p\,|^2)/(\,|\,s\,|^2 + \,|\,p\,|^2) \ , \end{split}$$

where s=A and  $p=|\mathbf{p}_f|B/(E_f+m_f)$ ; here  $E_f$  and  $\mathbf{p}_f$  are the energy and momentum of the final baryon. The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1.$$

If the hyperon polarization is  $\mathbf{P}_Y$ , the polarization  $\mathbf{P}_B$  of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \widehat{\mathbf{n}}) \widehat{\mathbf{n}} + \beta (\mathbf{P}_Y \times \widehat{\mathbf{n}}) + \gamma \widehat{\mathbf{n}} \times (\mathbf{P}_Y \times \widehat{\mathbf{n}})}{1 + \alpha \mathbf{P}_Y \cdot \widehat{\mathbf{n}}}$$

Here  $\mathbf{P}_B$  is defined in the rest system of the baryon, obtained by a Lorentz transformation along  $\hat{\mathbf{n}}$  from the hyperon rest frame, in which  $\hat{\mathbf{n}}$  and  $\mathbf{P}_Y$  are defined.

An additional useful parameter  $\phi$  is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin \phi .$$

In the Listings, we compile  $\alpha$  and  $\phi$  for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions.

In the Baryon Summary Table, we give  $\alpha$ ,  $\phi$ , and  $\Delta$  (defined below) with errors, and also give the value of  $\gamma$  without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that  $\beta=0$ . However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s| e^{i\delta_s}$$
 and  $p = |p| e^{i\delta_p}$ ,

where  $\delta_s$  and  $\delta_p$  are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p).$$

One also defines  $\Delta = -\tan^{-1}(\beta/\alpha)$ . If T invariance holds,  $\Delta = \delta_s - \delta_p$ . For  $\Lambda \to p\pi^-$  decay, the value of  $\Delta$  may be compared with the s- and p-wave phase shifts in low-energy  $\pi^-p$  scattering, and the results are consistent with T invariance.

#### Radiative hyperon decays

For the radiative decay of a polarized spin-1/2 hyperon,  $B_i \to B_f \gamma$ , the angular distribution of the direction  $\hat{p}$  of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{d\Gamma_{\gamma}}{d\Omega} = \frac{\Gamma_{\gamma}}{4\pi} \left( 1 + \alpha_{\gamma} \widehat{p} \cdot \mathbf{P}_{i} \right) ,$$

where  $\mathbf{P}_i$  is the hyperon polarization and the asymmetry parameter  $\alpha_{\gamma}$  is

$$\alpha_{\gamma} = \frac{2\text{Re}\left[g_1'(0)f_M^*(0)\right]}{|g_1'(0)|^2 + |f_M(0)|^2}$$

Here  $f_M=\frac{(m_i-m_f)}{(m_i+m_f)}\left[(m_i+m_f)f_2'-f_1'\right]$ , where  $f_1'(q^2)$ ,  $f_2'(q^2)$ , and  $g_1'(q^2)$  are the  $\Delta Q=0$  analogs of the  $|\Delta Q|=1$  form factors defined above.

#### NOTE ON N AND A RESONANCES

#### I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The masses, widths, and elasticities of the N and  $\Delta$  resonances in the Baryon Summary Table come almost entirely from partial-wave analyses of  $\pi N$  total, elastic, and charge-exchange scattering data (Sec. II). Partial-wave analyses have also been performed on much smaller data sets to get  $N\eta$ ,  $\Lambda K$ , and  $\Sigma K$  branching fractions. Other branching fractions come from isobar-model analyses of  $\pi N \to N\pi\pi$  data (Sec. III). Finally, many  $N\gamma$ branching fractions have been determined from photoproduction experiments (Sec. IV).

Table 1 lists all the N and  $\Delta$  entries in the Baryon Listings and gives our evaluation of the status of each, both overall and channel by channel. Only the "established" resonances (overall status 3 or 4 stars) appear in the Baryon Summary Table. We consider a resonance to be established only if it has been seen in at least two independent analyses of elastic scattering and if the relevant partial-wave amplitudes do not behave erratically or have large uncertainties.

The Baryon Particle Listings give, in addition to the usual Breit-Wigner parameters, the positions and residues of the nearest poles of the resonant partial waves on the second sheet of the complex energy plane. These come from  $\pi N \to \pi N$ partial-wave analyses and from a  $\pi N \to N\pi\pi$  isobar-model analysis (Sec. III).

The interested reader will find further discussions in two extensive (but now somewhat dated) reviews [1,2] and in the Proceedings of the 6th International Symposium on Meson-Nucleon Physics and the Structure of the Nucleon [3].

(References for this Section are at the end of Sec. II.)

Table 1. The status of the N and  $\Delta$  resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table

		o	Status as seen in —

Existence is certain, and properties are at least fairly well explored. Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined. Evidence of existence is only fair.

Evidence of existence is poor

## II. Elastic partial-wave analyses and resonance param-

(by R.L. Workman, Virginia Polytechnic Institute and State University)

A general discussion was given in previous editions [4]. In the following, we only consider new results.

New data: Experimental activity over the past two years has mainly concentrated on the region below 600 MeV [5]. Some of these data remain in preliminary form. The new pionic atom measurement [6] from PSI is particularly interesting as it has updated the  $\pi N$  scattering lengths used in dispersion

## N's and $\Delta$ 's

relations. An experiment at the ITEP accelerator has measured spin-rotation parameters for  $\pi^+p$  elastic scattering at 1.43 GeV/c [7]. The results are surprising, as they strongly contradict predictions from the CMU-Berkeley (CMB) [8] and Karlsruhe-Helsinki (KH) [9] analyses. More spin-rotation measurements are planned for this energy region.

**New Partial-Wave Analyses:** The VPI group has updated its resonance parameters [10]. The new determinations are based upon a partial-wave analysis with fixed-t dispersion relation constraints. A search was made for 'small' structures, and two new resonance candidates were found. Discrepancies between this analysis and the CMB [8] and KH [9] analyses still exist.

Batinić et al. [11] have used a coupled-channel model to describe the elastic  $\pi N$  amplitudes together with data for  $\pi N \to \eta N$ . One variant of this model contains two additional  $(S_{11} \text{ and } P_{11})$  resonances with masses near 1750 MeV. The extra  $S_{11}$  resonance is similar to one of the small structures found in the VPI analysis. While there is other circumstantial evidence [12] for this state, further verification is needed.

The Petersburg analysis [13] is now published. The associated preprint was described in the 1992 review. While the published version does not report some of the higher partial waves, the partial-wave solutions are identical.

Resonance Parameters: Höhler has generated pole parameters for the KH solution using the speed-plot method. This study is continuing [14]. Manley [15] has related and compared the pole and Breit-Wigner parameters from the KSU [16], CMB [8], KH [9], and VPI [10] analyses. Good agreement was found for the  $\Delta(1232) P_{33}$ ,  $N(1520) D_{13}$ ,  $N(1650) S_{11}$ ,  $N(1675) D_{15}$ ,  $N(1680) F_{15}$ , and  $\Delta(1950) F_{37}$  pole parameters. The most recent VPI analysis has added a small structure to the high-energy shoulder of the  $N(1650) S_{11}$ . As a result, the associated parameters have changed significantly.

## III. Inelastic two-body and quasi-two-body reactions

(by D.M. Manley, Kent State University)

Since the last edition, no new data nor partial-wave analyses have been published for the inelastic two-body reactions  $\pi N \to \Lambda K$  and  $\pi N \to \Sigma K$ . However, new data have been measured and a new analysis published for the  $\pi N \to N\eta$  reaction. In particular, an experiment [1] that measured the cross section for  $\pi^-p \to n\eta$  from threshold to  $p_\pi = 750~{\rm MeV/c}$  ( $\sqrt{s} = 1527~{\rm MeV}$ ) was recently completed using the AGS at Brookhaven National Laboratory. In addition, the same collaboration also measured the cross section for  $K^-p \to \Lambda \eta$ . The data from these measurements are currently being analyzed.

A new energy-dependent partial-wave analysis of the reaction  $\pi N \to N \eta$  has also been published [2]. The analysis used a coupled three-channel model to describe reactions involving the  $N\pi$  and  $N\eta$  channels simultaneously. (The third channel was an effective nonphysical two-body  $N\pi\pi$  channel.) The eight lowest  $I=\frac{1}{2}$   $\pi N\to N\eta$  partial waves were fitted up to a c.m. energy of 2.5 GeV using the  $\pi N$  elastic amplitudes from the Karlsruhe-Helsinki partial-wave analysis [3] as part of the input data base.

Essentially all information on quasi-two-body reactions such as  $\pi N \to \Delta \pi$  and  $\pi N \to N \rho$  comes from isobar-model analyses of  $\pi N \to N \pi \pi$  reactions. Since the last edition, no new analysis of these reactions has been published. A brief review of  $\pi N \to N \pi \pi$  analyses can be found in our 1992 edition; for a more recent and extensive review, the interested reader should see [4].

Since the last edition, two new narrow resonance candidates were observed in experiments investigating the diffractive production of hadrons by 70-GeV protons at the SPHINX facility of the IHEP accelerator [5]. In the reaction on carbon nuclei,  $p+C \rightarrow [\varSigma(1385)^0K^+]+C$ , evidence was found for an N(2050) with mass  $M=(2052\pm 6)$  MeV and width  $\Gamma=35^{+22}_{-35}$  MeV. In the reaction,  $p+C \rightarrow [\varSigma^0K^+]+C$ , evidence was found for an N(2000) with  $M=1999\pm 6$  MeV and  $\Gamma=91\pm 17$  MeV.

# Baryon Particle Listings N's and $\Delta$ 's

The small decay widths and large branching ratios for decays involving hyperons make these states candidates for exotic  $qqqs\bar{s}$  baryons. Further evidence suggesting the possible existence of narrow exotic baryons was found by a recent analysis of photographic data obtained during irradiation of the 2-meter hydrogen bubble chamber at CERN by a 16-GeV/c  $\pi^-$  beam [6]. A narrow peak that may be due to the production of a neutral baryon with  $M=3521\pm3$  MeV and  $\Gamma=6^{+21}_{-6}$  MeV was observed in the invariant mass spectrum of the  $K^0_sK^+p\pi^-\pi^-$  system.

## IV. Electromagnetic interactions

(by R.L. Crawford, University of Glasgow)

Nearly all the entries in the Listings relating to electromagnetic properties of the N and  $\Delta$  resonances are  $N\gamma$  couplings. These couplings, the helicity amplitudes  $A_{1/2}$  and  $A_{3/2}$ , have been obtained in a large number of partial-wave analyses of single-pion photoproduction,  $\gamma N \to \pi N$ , on protons and neutrons. The large amount of data has permitted an accurate evaluation of the couplings for many of the resonances with masses below 2 GeV, and has given at least qualitative information about most of the others. Most photoproduction analyses take as input the existence, masses, and widths of the resonances derived from the  $\pi N \to \pi N$  analyses, and only determine the  $N\gamma$ couplings. In addition to the pion photoproduction analyses, a few couplings have been extracted from  $\eta$  photoproduction and from Compton scattering. A brief description of the various methods of analysis of photoproduction data may be found in our 1992 edition [1]

Our Listings omit a number of analyses that are now obsolete. Most of the older results may be found in our 1982 edition [2]. The errors quoted for the couplings in the Listings are calculated in different ways in different analyses and therefore should be used with care. In general, the systematic differences between the analyses caused by using different

parametrization schemes are probably more indicative of the true uncertainties than are the quoted errors.

Probably the most reliable analyses are ARAI 80, CRAW-FORD 80, AWAJI 81, FUJII 81, CRAWFORD 83, and ARNDT 96. The Listings include our estimates of the couplings, using the results of these analyses. The errors we give are a combination of the stated statistical errors on the analyses and the systematic differences between them. The analyses are given equal weight, except ARNDT 96 is weighted, rather arbitrarily, by a factor of two because its data set is at least 50% larger than those of the other analyses and contains many new high-quality measurements.

The Baryon Summary Table gives  $N\gamma$  branching fractions for those resonances whose couplings are considered to be reasonably well established. The  $N\gamma$  partial width  $\Gamma_{\gamma}$  is given in terms of the helicity amplitudes  $A_{1/2}$  and  $A_{3/2}$  by

$$\Gamma_{\gamma} = \frac{k^2}{\pi} \frac{2M_N}{(2J+1)M_R} \left[ |A_{1/2}|^2 + |A_{3/2}|^2 \right].$$

Here  $M_N$  and  $M_R$  are the nucleon and resonance masses, J is the resonance spin, and k is the photon c.m. decay momentum.

The Listings include results of several new analyses of the  $N(1535) \to N\gamma$  couplings obtained using recent accurate measurements of the reaction  $\gamma N \to N\eta$  near threshold.

Burkert and Elouadrhiri [4] report the result of an analysis of  $\pi^0$  electroproduction on protons at a virtual photon mass of  $Q^2 = -3.2 \; (\text{GeV}/c)^2$  using data from DESY. They evaluated the ratio of electric quadrupole and scalar quadrupole to magnetic dipole amplitudes for the  $\Delta(1232)$ . Their values,

$$E_{1+}/M_{1+} = 0.06 \pm 0.02 \pm 0.03$$

and

$$S_{1+}/M_{1+} = 0.07 \pm 0.02 \pm 0.03$$
,

agree with typical quark model predictions and are qualitatively similar to those obtained from previous analyses for smaller values of  $|Q^2|$ . They disagree with the predictions from perturbative QCD that  $E_{1+}/M_{1+} \to 1$  and  $S_{1+}/M_{1+} \to 0$  at large  $|Q^2|$ .

Mart, Bennhold, and Hyde-Wright [5] apply isobar models developed for  $\gamma p \to K^+ \varSigma^0$  and  $\gamma p \to K^+ \Lambda$  to  $\gamma p \to K^0 \varSigma^+$  and  $\gamma n \to K^- \varSigma^+$  and find that they can drastically overpredict the measurements. Including the data for charged  $\varSigma$  production results in drastically reduced values for the Born-term couplings,  $g_{K\varSigma N}$  and  $g_{K\Lambda N}$ , to values well below the SU(3) predictions and values obtained from hadronic processes. The resulting description of the process is resonance dominated. They point out the importance for future analyses of including data for all channels. Their results are not included in the Listings because of the scatter of the values obtained.

Additional information about recent results for the electromagnetic interactions may be found in our 1992 and 1994

## N's and $\Delta$ 's

editions [1,3]. These include Compton scattering,  $K\Lambda$  photoproduction, pion electroproduction, the E2/M1 ratio, and the magnetic moment of the  $\Delta(1232)$ .

#### V. Outlook

(by D.M. Manley, Kent State University)

Much new data related to the study of nucleon resonances will soon come from experiments with electromagnetic probes at CEBAF, which can provide beams of electrons to three experimental halls (A, B, and C) with energies up to 4 GeV. Experiments are now being carried out in Hall C and the commissioning experiments for Hall A are expected to run in mid 1996. The majority of experiments to study nucleon resonances will be carried out in Hall B, which is expected to be completed in late 1996. A very short summary of the experimental program in Hall B can be found in our last edition.

New experiments to study nucleon resonances at European laboratories are already producing interesting results. For example, measurements of total cross sections for the reaction  $\gamma p \rightarrow p \eta$  at eight c.m. energies between 1487 and 1493 MeV were performed at the ELSA electron facility at Bonn [1] by solely detecting the recoil proton. In addition, very precise measurements of total and differential cross sections for  $\gamma p \to p \eta$ from threshold to 1537 MeV (c.m. energy) were performed using the MAMI accelerator in Mainz [2] with the neutral meson spectrometer TAPS. Other facilities are or will be involved in such programs using hadronic beams. For example, two experiments were approved in 1995 to study baryon spectroscopy at the AGS of Brookhaven National Laboratory. The processes,  $\pi^- p \to n\eta$ ,  $K^-p \to \Lambda \eta$ , and  $K^-p \to \Sigma^0 \eta$ , among others, will be studied by using the Crystal Ball detector (formerly located at SLAC) to identify multiphoton final states [3,4]. As by-products of these investigations, new and improved data also will be obtained for  $\pi^- p \to n\pi^0$ , and for the inverse photoproduction reactions,  $K^-p \to \Lambda \gamma$  and  $K^-p \to \Sigma^0 \gamma$ .

## VI. Non-qqq baryon candidates

The standard quark-model assignments for baryons are outlined in Sec. 12.3 "Baryons: qqq states". As in the meson spectrum (see the "Note on Non- $q\bar{q}$  mesons"), there have been suggestions that some states fall outside this assignment scheme. These include hybrid (qqqg) baryons and unstable meson-nucleon bound states [1] (see the "Note on the  $\Lambda(1405)$ ").

If non-qqq states exist, they will be more difficult to verify than hybrid mesons. Hybrid baryons would not have the clean signature of exotic quantum numbers. They should also mix with ordinary qqq states. The identification of such states will be based upon (a) characteristics of their formation and decay, and (b) an over-population of expected qqq states.

Most investigations have focused on the properties of the lightest predicted hybrids. If the first hybrid state lies below 2 GeV, as is suggested by bag-model calculations [2,3,4], it may already exist in the Baryon Particle Listings. (Note, however, that some estimates [5] put the lightest state significantly above 2 GeV.) At present, there are actually not enough known resonances to fill the known multiplets. This is the 'missing resonance' problem. If an existing resonance is identified as a hybrid, we must also account for the expected qqq state.

The Roper resonance,  $N(1440) P_{11}$ , has been considered as a hybrid candidate based upon its quantum numbers [2] and difficulties with its mass and electromagnetic couplings. If so, this would alter our interpretation of the low-lying  $P_{11}$ ,  $P_{13}$ ,  $P_{31}$ , and  $P_{33}$  resonances [2,6]. In Ref. 6, both the  $N(1440) P_{11}$  and  $\Delta(1600) P_{33}$  are hybrid candidates, and the  $N(1540) P_{13}$  and  $\Delta(1550) P_{31}$  states are predicted. The  $P_{13}$  and  $P_{31}$  (1-star) states were listed in the 1990 RPP [7] but were removed from the listings in 1992 [8].

Both photoproduction [6,9,10] and electroproduction [10,11] have been considered in the search for a unique hybrid signature. In Ref. 12, QCD counting rules were used to reveal a characteristic of hybrid electroproduction at high  $Q^2$ . If the Roper is a hybrid, its transverse form factor is expected to fall asymptotically  $\mathrm{O}(1/Q^2)$  faster than a pure qqq state. However, mixing between qqq and qqqg states will make this identification more difficult.

A number of recent experiments have searched for pentaquark  $(qqqq\bar{q})$  resonances and H-dibaryon (six-quark uuddss states). Narrow structures found in proton-nucleus scattering [13] have been attributed to  $qqqs\bar{s}$  states (see Sec. III), but these require confirmation. The H-dibaryon experiments, while finding possible candidates, have generally quoted upper limits [14] for exotic resonance production. Searches for narrow dibaryons in the nucleon-nucleon interaction are also continuing [15].

For an extensive review of exotic hadrons, see Landsberg [16].

0.062	¹¹ NOELLE	78	$\gamma N \rightarrow \pi N$

## N(1440) FOOTNOTES

- $^1\, {\rm BAKER}$  79 finds a coupling of the N(1440) to the N  $\eta$  channel near (but slightly below)
- threshold. 
  2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes. 
  3 From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix

- From method II of LONGACKE 75. Eyeuan inc with real part = 1383 MeV, -2×imaginary part = 210 MeV, and residue with modulus 92 MeV and phase = -54°.
   See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and A resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

- 6  ARNDT 91 (Soin SM90) also finds a second-sheet pole with real part =1413 MeV,  $-2\times$  imaginary part =256 MeV, and residue  $=(78-153\emph{i})$  MeV.
- ⁷ LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- An alternative which cannot be distinguished from this is to have a  $P_{13}$  resonance with M=1530 MeV,  $\Gamma=79$  MeV, and elasticity =+0.271. PLONGACRE 77 considers this coupling to be well determined.
- 10  WADA 84 is inconsistent with other analyses; see the Note on N and  $\Delta$  Resonances.
- 11  Converted to our conventions using M=1486 MeV,  $\Gamma=613$  MeV from NOELLE 78.

## N(1520) FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi\,N\,\rightarrow\,N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- This with Breit-Wigner Circles to the 1-matrix amplitudes.

  2 From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- amplitudes. ³ See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. ⁴ LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. ⁵ LONGACRE 77 considers this coupling to be well determined.
- Converted to our conventions using M=1528 MeV,  $\Gamma=187$  MeV from NOELLE 78.

## N(1535) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction $(\Gamma_i/\Gamma)$	
Γ ₁	Nπ	35-55 %	
$\Gamma_2$	$N\eta$	30-55 %	
$\Gamma_3$	$N\pi\pi$	1-10 %	
$\Gamma_4$	$\Delta\pi$	<1 %	
Γ ₅	$\Delta(1232)\pi$ , $D$ -wave		
$\Gamma_6$	$N\rho$	<4 %	
$\Gamma_7$	$N\rho$ , $S=1/2$ , $S$ -wave		
Γ8	$N\rho$ , $S=3/2$ , $D$ -wave		
Γ9	$N(\pi\pi)_{S-\text{wave}}^{I=0}$	<3 %	
$\Gamma_{10}$	$N(1440)\pi$	<7 %	
$\Gamma_{11}$	$p\gamma$	0.08-0.27 %	
$\Gamma_{12}$	$p\gamma$ , helicity=1/2	0.08-0.27 %	
$\Gamma_{13}$	$n\gamma$	0.004-0.29 %	
Γ ₁₄	$n\gamma$ , helicity=1/2	0.004-0.29 %

Note: Signs of couplings from  $\pi N \to N \pi \pi$  analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the  $\Delta(1620)$   $S_{31}$ coupling to  $\Delta(1232)\pi$ .

## N(1535) FOOTNOTES

- 1  LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi\,N\to\,N\pi\,\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ² From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- amplitudes.  3  See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4 LONGACE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 5 BENMERROUCHE 91 uses an effective Lagrangian approach to analyze  $\eta$  photoproduc-
- tion data. 6 Converted to our conventions using M=1548 MeV,  $\Gamma=73$  MeV from NOELLE 78.

## N(1650) FOOTNOTES

- 1  ARNDT 95 finds two distinct states.  2  BATINIC 95 finds two distinct states. This second resonance was associated with the  $N(2090)~S_{11}$ .  3  The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from
- The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis. LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

  From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- rion mention in LONGACE 73: eyeball its win Breit-Wigner circles to the 1-matrix amplitudes. See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- TLONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- (CERN) partial-wave analysis.

  8 BAKER 79 fixed this coupling during fitting, but the negative sign relative to the N(1535) is well determined.

  9 The overall phase of BAKER 78 couplings has been changed to agree with previous conventions. Superseded by SAXON 80.

  10 The range given for DEANS 75 is from the four best solutions.

  11 LONGACRE 77 considers this coupling to be well determined.

## N(1675) FOOTNOTES

LI BARBOUR

\$\$ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to \$\pi N \to N\pi\pi\$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

\$\$\$ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

93 IPWA  $\gamma N \rightarrow \pi N$ 78 DPWA  $\gamma N \rightarrow \pi N$ 

- amplitudes.

  ³ See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters
- 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
   4 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to π N → Nππ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
   5 SAXON 80 finds the coupling phase is near 90°.
   6 The range given is from the four best solutions. DEANS 75 disagrees with π⁺ p → Σ⁺ K⁺ data of WINNIK 77 around 1920 MeV.
   7 LONGACRE 77 considers this coupling to be well determined.
   8 A Breit-Wigner fit to the HERNDON 75 IPWA.

## N(1680) FOOTNOTES

- \$\$ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to \$\pi N \to N\pi\pi\$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

  \$\$\$ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- amplitudes. 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4  LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi\,N\to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- ⁵ The parametrization used may be double counting.
- ⁶ The range given is from 3 of 4 best solutions; not present in solution 1. DEANS 75 disagrees with  $\pi^+ p \to \Sigma^+ K^+$  data of WINNIK 77 around 1920 MeV.
- 7 LONGACRE 77 considers this coupling to be well determined.
  8 A Breit-Wigner fit to the HERNDON 75 IPWA.

## $N(1700) D_{13}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$$
 Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters 111B (1982).

The various partial-wave analyses do not agree very well.

## N(1700) FOOTNOTES

- $^{\rm 1}\,{\rm The}$  two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from
- ^ Ine two BAKER // entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis. 
  ^ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ³ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- ⁴ See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. 5 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 6 The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.
  7 The range given is from the four best solutions.

## $\overline{N(1710)} \ P_{11}$

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters 111B (1982).

The various partial-wave analyses do not agree very well.

## N(1710) FOOTNOTES

- $^1\,\text{BATINIC}$  95 finds a second state with a 6 MeV mass difference.  $^2\,\text{The}$  two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.
- a Conventional energy-dependent analysis. 3 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ⁴ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- amplitudes and from piots of the speeds with which the amplitudes traverse the diagrams. CLONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

  7 The overall phase of BAKER 78 couplings has been changed to agree with previous
- conventions.

  8 The range given for DEANS 75 is from the four best solutions.

## N(1720) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction $(\Gamma_i/\Gamma)$
Γ1	Nπ	10-20 %
$\Gamma_2$	$N\eta$	
Γ3	ΛK	1-15 %
$\Gamma_4$	ΣΚ	
$\Gamma_5$	$N\pi\pi$	>70 %
$\Gamma_6$	$\Delta\pi$	
$\Gamma_7$	$\Delta(1232)\pi$ , $\it P$ -wave	
Γ ₈	$N\rho$	70-85 %
Γ9	$N\rho$ , $S=1/2$ , $P$ -wave	
Γ ₁₀	$N\rho$ , $S=3/2$ , $P$ -wave	
Γ11	$N(\pi\pi)_{S-\text{wave}}^{I=0}$	
$\Gamma_{12}$	$p\gamma$	0.003-0.10 %
$\Gamma_{13}$	$p\gamma$ , helicity=1/2	0.003-0.08 %
$\Gamma_{14}$	$p\gamma$ , helicity=3/2	0.001-0.03 %
$\Gamma_{15}$	$n\gamma$	0.002-0.39 %
Γ ₁₆	$n\gamma$ , helicity=1/2	0.0-0.002 %
Γ ₁₇	$n\gamma$ , helicity=3/2	0.001-0.39 %

## N(1720) FOOTNOTES

- 1  The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.  2  LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- fits with Breit-Wigner circles to the 1-matrix amplitudes. 3 From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes. 4 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 5 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- ⁶ The overall phase of BAKER 78 copulings has been changed to agree with previous
- conventions. ⁷ The range given is from the four best solutions. DEANS 75 disagrees with  $\pi^+ p \rightarrow$  $\Sigma^+ K^+$  data of WINNIK 77 around 1920 MeV.

## $N(2080) D_{13}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2})$$
 Status: **

## OMITTED FROM SUMMARY TABLE

There is some evidence for two resonances in this wave between 1800 and 2200 MeV (see CUTKOSKY 80). However, the solution of HOEHLER 79 is quite different.

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters 111B (1982).

## N(2090) FOOTNOTES

 1  LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi\,N\,\to\,\,N\,\pi\,\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

 $^{^1}$  See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.  2  The range given for DEANS 75 is from the four best solutions. Disagrees with  $\pi^+ \, \rho \to \Sigma^+ \, K^+$  data of WINNIK 77 around 1920 MeV.

#### $\Delta$ (1232) PHASE OF M1+(3/2) PHOTOPRODUCTION MULTIPOLE AMPLITUDE POLE RESIDUE

Information on the phase (and magnitude) of the M1+(3/2) multipole amplitude pole residue is contained implicitly in the paper of MIROSH-NICHENKO 79. They find that the phase is consistent with being equal to that of the elastic pole residue.

## △(1232)⁺⁺ MAGNETIC MOMENT

The values are extracted from UCLA and SIN data on  $\pi^+\,p$  bremsstrahlung using a variety of different theoretical approximations and methods. Our estimate is only a rough guess of the range we expect the moment to lie

3.7 to 7.5 OUR EST	TIMATE	
• • We do not use	the following dat	a for averages, fits, limits, etc. • •
1.52 ± 0.50 ± 0.45	BOSSHARD	91 $\pi^+ \rho \rightarrow \pi^+ \rho \gamma$ (SIN data)
3.7 to 4.2	LIN	918 $\pi^+ p \rightarrow \pi^+ p \gamma$ (from UCLA data)
1.6 to 4.9	LIN	91B $\pi^+ p \rightarrow \pi^+ p \gamma$ (from SIN data)
5.6 to 7.5	WITTMAN	88 $\pi^+ p \rightarrow \pi^+ p \gamma$ (from UCLA data)
5.9 to 9.8	HELLER	87 $\pi^+ p \rightarrow \pi^+ p \gamma$ (from UCLA data)
1.7 to 6.7	NEFKENS	78 $\pi^+ p \rightarrow \pi^+ p \gamma$ (UCLA data)

## △(1232) FOOTNOTES

- 1 Using  $\pi^\pm d$  as well, PEDRONI 78 determine  $(M^- M^{++}) + (M^0 M^+)/3 = 4.6 \pm 0.2$  MeV. 2 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ³ This VASAN 76B value is from fits to the coulomb-barrier-corrected CARTER 73 phase
- shift. 4 This VASAN 768 value is from fits to the CARTER 73 nuclear phase shift without coulomb barrier corrections. 5 Converted to our conventions using M=1232 MeV,  $\Gamma=110$  MeV from NOELLE 78.

## △(1600) FOOTNOTES

- ¹ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ² From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. 4 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first
- (second) value uses, in addition to  $\pi\,N\to\,$   $\dot{N}\,\pi\,\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- The range given is from the four best solutions. DEANS 75 disagrees with  $\pi^+ \rho \rightarrow$  $\Sigma^+ K^+$  data of WINNIK 77 around 1920 MeV.
- 6 LONGACRE 77 considers this coupling to be well determined.
- 7  WADA 84 is inconsistent with other analyses see the Note on N and  $\Delta$  Resonances.

## △(1620) FOOTNOTES

- ¹ CHEW 80 reports two  $S_{31}$  resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83. 
  ² LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N\pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ³ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- From method no LONGACKE 75: eyebali its with breit-wigher circles to the 1-matrix amplitudes. 4 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 5 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- ⁶ LONGACRE 77 considers this coupling to be well determined.

## △(1700) FOOTNOTES

 1  Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83.  2  LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.  3  From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

Shrom method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes. See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. SLONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N \pi \pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

 6  The range given is from the four best solutions. DEANS 75 disagrees with  $\pi^+p \to$ 

 7  K+ data of WINNIK 77 around 1920 MeV. 7 LONGACRE 77 considers this coupling to be well determined.

### △(1910) FOOTNOTES

- $^1\text{CHEW}$  80 reports four resonances in the  $P_{31}$  wave see also the  $\Delta(1750).$  Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.  2  LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- Its with Breit-Wigner circies to the 1-matrix amplitudes. 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. 4 The range given for DEANS 75 is from the four best solutions. 5 Evidence for this coupling is weak; see NOVOSELLER 78. This coupling assumes the mass is near 1820 MeV.

### △(1950) FOOTNOTES

- $^{
  m 1}$  From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- amplitudes.  2  See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.  2  LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \to N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- (LERN) partial-wave analysis.

  4 The range given is from the four best solutions. DEANS 75 disagrees with  $\pi^+ \rho \to \Sigma^+ K^+$  data of WINNIK 77 around 1920 MeV.

  5 A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near  $-60^\circ$ .

  6 A Breit-Wigner fit to the NOVOSELLER 788 IPWA; the phase is near  $-60^\circ$ .

- ⁷A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near 120°.
- ⁸ A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near 120°.

 $^{^1}$  See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi$  N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

 $\Delta$ ( $\sim$  3000)

# $\Delta (\sim$ 3000 Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a  $\Delta(2850)$  and a  $\Delta(3230)$ . The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The  $\Delta(2850)$  has been resolved into the  $\Delta(2750)$  /_{3,13} and  $\Delta(2950)$   $K_{3,15}$ . The  $\Delta(3230)$  is perhaps related to the  $K_{3,13}$  of HENDRY 78 and to the  $L_{3,17}$  of KOCH 80.

### BARYON MAGNETIC MOMENTS

The figure shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured p, n, and  $\Lambda$  moments as input. In this model, the moments are [1]

$$\begin{array}{ll} \mu_p = (4\mu_u - \mu_d)/3 & \mu_n = (4\mu_d - \mu_u)/3 \\ \mu_{\varSigma^+} = (4\mu_u - \mu_s)/3 & \mu_{\varSigma^-} = (4\mu_d - \mu_s)/3 \\ \mu_{\varSigma^0} = (4\mu_s - \mu_u)/3 & \mu_{\varSigma^-} = (4\mu_s - \mu_d)/3 \\ \mu_{\varLambda} = \mu_s & \mu_{\varSigma^0} = (2\mu_u + 2\mu_d - \mu_s)/3 \\ \mu_{\varOmega^-} = 3\mu_s \end{array}$$

and the  $\Sigma^0 \to \Lambda$  transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3} .$$

### Λ

The quark moments that result from this model are  $\mu_u = +1.852 \, \mu_N$ ,  $\mu_d = -0.972 \, \mu_N$ , and  $\mu_s = -0.613 \, \mu_N$ . The corresponding effective quark masses, taking the quarks to be Dirac point particles, where  $\mu = q\hbar/2m$ , are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

#### CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2=10.5$  for 16 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\left\langle \delta \kappa_i \delta \kappa_j / (\delta \kappa_i \cdot \delta \kappa_j) \right\rangle$ , in percent, from the fit to the branching fractions,  $\kappa_i \equiv \Gamma_i / \Gamma_{\text{total}}.$  The fit constrains the  $\kappa_i$  whose labels appear in this array to sum to one.

 9  CHAUVAT 85 actually gives  $\alpha_+(\overline{\Lambda})/\alpha_-(\Lambda)=-1.04\pm0.29$ . Assumes polarization is same in  $\overline{p}\,p\to\overline{\Lambda}{\rm X}$  and  $p\,p\to\Lambda{\rm X}$ . Tests of this assumption, based on C-invariance and fragmentation, are satisfied by the data.

 $g_A$  /  $g_V$  FOR  $\Lambda \to pe^-\overline{\nu}_e$  Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. The measurements all assume that the form factor  $g_2=0$ . See also the footnote on DWORKIN 90. EVTS DOCUMENT ID TECN COMMENT

### $\Lambda$ AND $\Sigma$ RESONANCES

**Introduction:** There are no new results at all on  $\Lambda$  and  $\Sigma$  resonances. The field remains at a standstill and will only be revived if a kaon factory is built. What follows is a much abbreviated version of the note on  $\Lambda$  and  $\Sigma$  Resonances from our 1990 edition. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each  $\Lambda$  and  $\Sigma$  resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes  $A_0$  and  $A_1$ , the amplitude for  $K^-p \to \overline{K}^0 n$  scattering is  $\pm (A_1 - A_0)/2$ , where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the  $\Sigma(1775)D_{15}$  amplitude at resonance points along the positive imaginary axis (points "up"), then any  $\Sigma$  at resonance will point "up" and any  $\Lambda$  at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the  $\overline{K}N \to \Lambda\pi$  and  $\overline{K}N \to \Sigma\pi$  amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [1] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or - sign in front of a measurement of an inelastic resonance coupling indicates the sign (the absence of a sign means that the sign is not determined, not that it is positive). For more details, see Appendix II of our 1982 edition [2].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used.

Table 1. The status of the  $\Lambda$  and  $\Sigma$  resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

- **** Existence is certain, and properties are at least fairly well explored.

  Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.
- ** Evidence of existence is only fair.
- * Evidence of existence is only

Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the  $\Lambda(1520)$ , the  $\Lambda(1820)$ , and the  $\Sigma(1775)$ , there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

**Production experiments:** Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The  $\Sigma(1385)$  and  $\Lambda(1405)$  of course lie below the  $\overline{K}N$  threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of  $\Lambda(1520)$  and results have been combined. There is some disagreement between production and formation experiments in the 1600-1700 MeV region: see the note on the  $\Sigma(1670)$ .

 $\Lambda(1405) S_{01}$ 

 $I(J^P) = 0(\frac{1}{2})$  Status: ***

THE  $\Lambda(1405)$ 

(by R.H. Dalitz, Oxford University)

It is generally accepted that the  $\Lambda(1405)$  is a well-established  $J^P = 1/2^-$  resonance. It is assigned to the lowest L = 1supermultiplet of the 3-quark system and paired with the  $J^P = 3/2^- \Lambda(1520)$ . Lying about 30 MeV below the  $N\overline{K}$ threshold, the  $\Lambda(1405)$  can be observed directly only as a resonance bump in the  $(\Sigma\pi)^0$  subsystem in final states of production experiments. It was first reported by ALSTON 61B in the reaction  $K^-p \to \Sigma\pi\pi\pi$  at 1.15 GeV/c and has since been seen in at least eight other experiments. However, only two of them had enough events for a detailed analysis: THOMAS 73. with about 400  $\Sigma^{\pm}\pi^{\mp}$  events from  $\pi^{-}p \to K^{0}(\Sigma\pi)^{0}$  at 1.69 GeV/c; and HEMINGWAY 85, with 766  $\Sigma^+\pi^-$  and 1106  $\Sigma^-\pi^+$  events from  $K^-p \to (\Sigma\pi\pi)^+\pi^-$  at 4.2 GeV/c, after the selections  $1600 \le M(\Sigma \pi \pi)^+ \le 1720$  MeV and momentum transfer  $< 1.0 \, (\text{GeV}/c)^2$  to purify the  $\Lambda(1405) \to (\Sigma \pi)^0$  sample. These experiments agree on a mass of about 1395-1400 MeV and a width of about 60 MeV. (Hemingway's mass of 1391  $\pm$  1 MeV is from his best, but unacceptably poor, Breit-Wigner fit.)

The Byers-Fenster tests on these data allow any spin and either parity: neither J nor P has yet been determined directly. The early indications for  $J^P=1/2^-$  came from finding Re  $A_{I=0}$  to be large and negative in a constant-scattering-length analysis of low-energy  $N\overline{K}$  reaction data (see KIM 65, SAKITT 65, and earlier references cited therein). The first multichannel energy-dependent K-matrix analysis (KIM 67) strengthened the case for a resonance around 1400–1420 MeV strongly coupled to the I=0 S-wave  $N\overline{K}$  system.

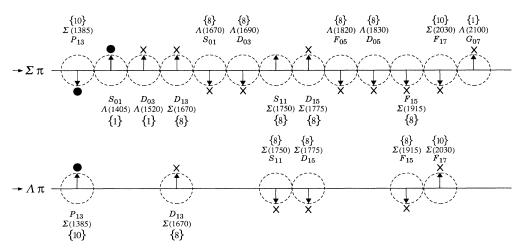

Figure 1. The signs of the imaginary parts of resonating amplitudes in the  $\overline{K}N \to \Lambda\pi$  and  $\Sigma\pi$  channels. The signs of the  $\Sigma(1385)$  and  $\Lambda(1405)$ , marked with a  $\bullet$ , are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an  $\times$ .

### Baryon Particle Listings A(1405)

THOMAS 73 and HEMINGWAY 85 both found the  $\Lambda(1405)$  bump to be asymmetric and not well fitted by a Breit-Wigner resonance function with constant parameters. The asymmetry involves a rapid fall in intensity as the  $N\overline{K}$  threshold energy is approached from below. This is readily understood as due to a strong coupling of the  $\Lambda(1405)$  to the S-wave  $N\overline{K}$  channel (see DALITZ 81). This striking S-shaped cusp behavior at a new threshold is characteristic of S-wave coupling; the other below-threshold hyperon, the  $\Sigma(1385)$ , has no such threshold distortion because its  $N\overline{K}$  coupling is P-wave. For the  $\Lambda(1405)$ , this asymmetry is the sole direct evidence that  $J^P=1/2^-$ .

Following the early work cited above, a considerable literature has developed on proper procedures for phenomenological extrapolation below the  $N\overline{K}$  threshold, partly in order to strengthen the evidence for the spin-parity of the  $\Lambda(1405)$ , and partly to provide an estimate for the amplitude  $f(N\overline{K})$  in the unphysical domain below the  $N\overline{K}$  threshold; the latter is needed for the evaluation of the dispersion relation for  $N\overline{K}$  and NK forward scattering amplitudes. For recent reviews, see MILLER 84 and BARRETT 89. In most recent work, the  $(\Sigma\pi)^0$  production spectrum is included in the data fitted (see, e.g., CHAO 73, MARTIN 81).

It is now accepted that the data can be fitted only with an S-wave pole in the reaction amplitudes below  $N\overline{K}$  threshold (see, however, FINK 90), but there is still controversy about the physical origin of this pole (for a review, see DALITZ 81 and DALITZ 82). Two extreme possibilities are: (a) an L=1 SU(3)-singlet uds state coupled with the S-wave meson-baryon systems; or (b) an unstable  $N\overline{K}$  bound state, analogous to the (stable) deuteron in the NN system. The problem with (a) is that the  $\Lambda(1405)$  mass is so much lower than that of its partner, the  $\Lambda(1520)$ . This requires, in the QCD-inspired quark model, rather large spin-orbit couplings, whether or not one uses relativistic kinetic energies. ISGUR 80, CAPSTICK 86, and CAPSTICK 89 conclude that a proper QCD calculation leads only to small energy splittings, whereas LEINWEBER 90, using QCD sum rules, obtains a good fit to this splitting.

On the other hand, the problem with (b) is that then another  $J^P=1/2^-\Lambda$  is needed to replace the  $\Lambda(1405)$  in the L=1 supermultiplet, and it would have to lie close to the  $\Lambda(1520)$ , a region already well explored by  $N\overline{K}$  experiments without result. Intermediate structures are possible; for example, the cloudy bag model allows the configurations (a) and (b) to mix and finds the intensity of (a) in the  $\Lambda(1405)$  to be only 14% (VEIT 84, VEIT 85, JENNINGS 86). Such models naturally predict a second  $1/2^-\Lambda$  close to the  $\Lambda(1520)$ .

The determination of the mass and width of the resonance from  $(\Sigma\pi)^0$  data is usually based on the "Watson approximation," which states that the production rate  $R(\Sigma\pi)$  of the  $(\Sigma\pi)^0$  state has a mass dependence proportional to  $(\sin^2\!\delta_{\Sigma\pi})/q$ , q being the  $\Sigma\pi$  c.m. momentum, in a  $\Sigma\pi$  mass range where  $\delta_{\Sigma\pi}$  is not far from  $\pi/2$  and only the  $\Sigma\pi$  channel is open, i.e., between the  $\Sigma\pi$  and the  $N\overline{K}$  thresholds. Then  $q\,R(\Sigma\pi)$  is proportional to  $\sin^2\!\delta_{\Sigma\pi}$ , and the mass M may be defined as the energy at

which  $\sin^2 \delta_{\Sigma\pi} = 1$ . The width  $\Gamma$  may be determined from the rate at which  $\delta_{\Sigma\pi}$  goes through  $\pi/2$ , or from the FWHM; this is a matter of convention.

This determination of M and  $\Gamma$  from the data suffers from the following defects:

- (i) The determination of  $\sin^2 \delta_{\Sigma\pi}$  requires that  $R(\Sigma\pi)$  be scaled to give  $\sin^2 \delta_{\Sigma\pi} = 1$  at the peak for the best fit to the data; *i.e.*, the bump must be assumed to arise from a resonance. However, this assumption is supported by the analysis of the low-energy  $N\overline{K}$  data and its extrapolation below threshold.
- (ii) Owing to the nearby  $N\overline{K}$  threshold, the shape of the best fit to the  $M(\Sigma\pi)$  bump is uncertain. For energies below this threshold at  $E_{N\overline{K}}$ , the general form for  $\delta_{\Sigma\pi}$  is

$$q\cot\delta_{\varSigma\pi} = \frac{1+\kappa\alpha}{\gamma+\kappa(\alpha\gamma-\beta^2)} \ .$$

Here  $\alpha, \beta$ , and  $\gamma$  are the (generally energy-dependent)  $NN, N\Sigma$ , and  $\Sigma\Sigma$  elements of the I=0 S-wave K-matrix for the  $(\Sigma\pi, N\overline{K})$  system, and  $\kappa$  is the magnitude of the (imaginary) c.m. momentum  $k_K$  for the  $N\overline{K}$  system below threshold. The elements  $\alpha, \beta, \gamma$  are real functions of E; they have no branch cuts at the  $\Sigma\pi$  and  $N\overline{K}$  thresholds, but they are permitted to have poles in E along the real E axis. The resonance asymmetry arises from the effect of  $\kappa$  on  $\delta_{\Sigma\pi}$ . We note that  $\delta_{\Sigma\pi}=\pi/2$  when  $\kappa=-1/\alpha$ .

Accepting this close connection of  $\delta_{\Sigma\pi}$  with the low-energy  $N\overline{K}$  data, it is natural to analyze the two sets of data together (e.g., MARTIN 81), and there is now a large body of accurate  $N\overline{K}$  data for laboratory momenta between 100 and 300 MeV/c (see MILLER 84). The two sets of data span c.m. energies from 1370 MeV to 1490 MeV, and the K-matrix elements will not be energy independent over such a broad range. For the I = 0 channels, a linear energy dependence for  $K^{-1}$  has been adopted routinely ever since the work of KIM 67, and it is essential when fitting the  $qR(\Sigma\pi)$  and  $N\overline{K}$  data together. However,  $q R(\Sigma \pi)$  is not always well fitted in this procedure; the value obtained for the  $\Lambda(1405)$  mass M varies a good deal with the type of fit, not a surprising result when the  $\Sigma\pi$ mass spectrum contributes only nine data points in a total of about 200. The value of M obtained from an overall fit is not necessarily much better than from one using only the  $qR(\Sigma\pi)$  data; and M may be a function of the representation— K-matrix, K⁻¹-matrix, relativistic-separable or nonseparable potentials, etc.— used in fitting over the full energy range. DALITZ 90 fitted the  $qR(\Sigma^+\pi^-)$  Hemingway data with each of the first three representations just mentioned, constrained to the I=0  $N\overline{K}$  threshold scattering length from low-energy  $N\overline{K}$  data. The (nonseparable) meson-exchange potentials of MÜLLER-GROELING 90, fitted to the low-energy  $N\overline{K}$  (and NK) data, predicted an unstable  $N\overline{K}$  bound state with mass and width compatible with the  $\Lambda(1405)$ .

The present status of the  $\Lambda(1405)$  thus depends heavily on theoretical arguments, a somewhat unsatisfactory basis for a four-star rating. Nevertheless, there is no known reason to

Г

doubt its existence or quantum numbers. A measurement of the energy-level shifts and widths for the atomic levels of kaonic hydrogen (and deuterium) would give a valuable check on analyses of the  $(\Sigma \pi, N\overline{K})$  amplitudes, since the energy of the  $K^-p$  atom lies roughly midway between those for the two sets of data. The three measurements of  $(\Delta E - i\Gamma/2)$  for kaonic hydrogen are inconsistent with one another and require that the sign of  $Re(A_{I=0} + A_{I=1})$  be opposite that deduced from  $N\overline{K}$  reaction data (see BATTY 89). Accurate measurements of  $(\Delta E - i\Gamma/2)$  values for kaonic hydrogen are badly needed, but may not be possible until the KAON factory becomes operational.

To definitively settle the nature of the  $\Lambda(1405)$  will require much further work, both experimental and theoretical. Higherstatistics experiments on the production and decay of the  $\Lambda(1405)$  are needed, but suitable  $K^-$  beams will not be available until KAON. The low-energy reaction cross sections, especially for the  $\overline{K}^0p$  interactions, last studied 25 years ago, need to be better determined.

### $\Lambda(1520)$

 $\Lambda(1520) D_{03}$ 

 $I(J^P) = O(\frac{3}{2}^-)$  Status: ***

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters 111B (1982).

Production and formation experiments agree quite well, so they are listed together here.

#### CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 24 measurements and one constraint to determine 6 parameters. The overall fit has a  $\chi^2$  = 16.5 for 19 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to

### Λ(1520) FOOTNOTES

- $^1\,\mathrm{From}$  the best-resolution sample of  $\varLambda\,\pi\,\pi$  events only.

- 1 From the best-resolution sample of  $A\pi\pi$  events only. 2 The  $\overline{K} N \to \Sigma \pi$  amplitude at resonance is  $+0.46 \pm 0.01$ . 3 Assumes  $\Gamma(N\overline{K})/\Gamma_{\text{total}} = 0.46 \pm 0.02$ . 4 Both  $\Sigma$  (1385)  $\pi$   $DS_{03}$  and  $\Sigma$  ( $\pi\pi$ )  $DP_{03}$  contribute. 5 The central bin (1514–1524 MeV) gives 0.74  $\pm$  0.10; other bins are lower by 2-to-5 standard deviations. 6 Much of the  $\Sigma \pi\pi$  decay proceeds via  $\Sigma$  (1385)  $\pi$ . 7 Assumes  $\Gamma(A|\overline{K})/\Gamma$  ... 0.46

- 7 Assumes  $\Gamma(NK)/\Gamma_{\rm total}=0.46$ . 8 Calculated from  $\Gamma(\Lambda\gamma)/\Gamma_{\rm total}$ , assuming SU(3). Needed to constrain the sum of all the branching ratios to be unity.

The above branching fractions are our estimates, not fits or averages.

### **Baryon Particle Listings** $\Lambda(1690), \Lambda(1800)$

### Λ(1690) BRANCHING RATIOS

The sum of all the quoted branching ratios is more than 1.0. The twobody ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the  $\Sigma\,\pi\pi$  bump looks more significant. (The error given for the  $\Lambda\pi\pi$  ratio looks unreasonably small.) Hardly any of the  $\Sigma \pi \pi$  decay can be via  $\Sigma$ (1385), for then seven times as much  $\Lambda \pi \pi$  decay would be required. See "Sign conventions for resonance couplings" in the Note on  $\varLambda$  and  $\varSigma$  Resonances.

## $\Lambda(1810) P_{01}$

$$I(J^P) = O(\frac{1}{2}^+)$$
 Status: ***

Almost all the recent analyses contain a  $P_{01}$  state, and sometimes two of them, but the masses, widths, and branching ratios vary greatly. See also the  $\Lambda(1600)$   $P_{01}$ .

### $\Lambda(1820) F_{05}$

$$I(J^P) = O(\frac{5}{2}^+)$$
 Status:  $****$ 

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

### **Λ(1820) FOOTNOTES**

- 1  The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.  2  There is a suggestion of a bump, enough to be consistent with what is expected from  $\Sigma(1385) \to \Sigma \pi$  decay.
- 3 The published sign has been changed to be in accord with the baryon-first convention.

 $\Lambda(1890), \Lambda(2000)$ 

 $\Lambda(1890) P_{03}$ 

$$I(J^P) = O(\frac{3}{2}^+)$$
 Status: ***

For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters 111B (1982).

The  $J^P=3/2^+$  assignment is consistent with all available data (including polarization) and recent partial-wave analyses. The dominant inelastic modes remain unknown.

### **Λ(1890) FOOTNOTES**

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- ² Found in one of two best solutions. ³ The published sign has been changed to be in accord with the baryon-first convention. ⁴ Upper limits on the  $P_3$  and  $F_3$  waves are each 0.03.

 $+0.09\pm0.03$ 

 $I(J^P) = 0(??)$  Status: *

#### OMITTED FROM SUMMARY TABLE

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are  $D_3$  (BARBARO-GALTIERI 70 in  $\Sigma \pi$ ),  $D_3+F_5$ ,  $P_3+D_5$ , or  $P_1+D_3$  (BRANDSTET-TER 72 in  $\Lambda\omega$ ), and  $S_1$  (CAMERON 78B in  $N\overline{K}^*$ ). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

### **Λ(2000) FOOTNOTES**

 1  The parameters quoted here are ranges from the three best fits; the lower state probably has  $J \le 3/2$ , and the higher one probably has  $J \le 5/2$ .

² The published sign has been changed to be in accord with the baryon-first convention.

#### OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either  $N \overline{K}$  or  $\Sigma \pi$ . With new  $K^- n$  angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

Discovered by COOL 66 and by WOHL 66. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters 170B (1986).

### A(2100) FOOTNOTES

- 1  The NAKKASYAN 75 values are from the two best solutions found. Each has the  $\Lambda(2100)$  and one additional resonance ( $P_3$  or  $F_5).$
- 2  Note that the three for BACCARI 77 entries are for three different waves.  3  The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the  $\it G_3$  wave is 0.03.

## $\Lambda(2325) D_{03}$

$$I(J^P) = O(\frac{3}{2}^-)$$
 Status: *

OMITTED FROM SUMMARY TABLE BACCARI 77 finds this state with either  $J^P=3/2^-$  or  $3/2^+$  in a energy-dependent partial-wave analyses of  $K^-p\to \Lambda\omega$  from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects 3/2 $^-$ . DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of  $K^-p \to \overline{K} N$  data, and finds  $J^P = 3/2^-$  or  $3/2^+$ . They again prefer  $J^P = 3/2^-$ , but only on the basis of model-dependent considerations.

Λ(2350) H₀₉

$$I(J^P) = O(\frac{9}{2}^+)$$
 Status: ***

DAUM 68 favors  $J^P=7/2^-$  or  $9/2^+$ . BRICMAN 70 favors  $9/2^+$ . LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find  $9/2^+$  in energy-dependent partial-wave analyses of  $\overline{K} N \to \Sigma \pi$ ,  $\Lambda \omega$ , and  $N \overline{K}$ .

#### **Σ**⁺ MAGNETIC MOMENT

See the "Note on Baryon Magnetic Moments" in the  $\it \Lambda$  Listings. Measurements with an error  $~\geq~0.1~\mu_{\it N}$  have been omitted.

VALUE (μ _N )	EVTS	DOCUMENT ID		TECN	COMMENT
2.458 ±0.010 OUR AVERAGE	E Error		r of	2.1. See	the ideogram
		below.			
$2.4613 \pm 0.0034 \pm 0.0040$	250k	MORELOS	93	SPEC	p Cu 800 GeV
$2.428 \pm 0.036 \pm 0.007$	12k	⁴ MORELOS	93	SPEC	p Cu 800 GeV
$2.479 \pm 0.012 \pm 0.022$	137k	WILKINSON	87	SPEC	p Be 400 GeV
$2.4040 \pm 0.0198$	44k	⁵ ANKENBRA	83	CNTR	<i>p</i> Cu 400 GeV

 $^{^4}$  We assume *CPT* invariance: this is (minus) the  $\overline{\Sigma}^-$  magnetic moment as measured by MORELOS 93. See below for the moment difference testing *CPT*.

 $^{^5}$  ANKENBRANDT 83 gives the value 2.38  $\pm$  0.02  $\mu_N$  . MORELOS 93 uses the same hyperon magnet and channel and claims to determine the field integral better, leading to the revised value given here.

 $(\mu_{\Sigma^+} - |\mu_{\overline{\Sigma}^-}|) / |\mu|_{\text{average}}$ 

_	. –	-	
A test of CPT invariance.			
ALUE	DOCUMENT ID	TECN	COMMENT
.014±0.015	6 MORELOS 93	SPEC	<i>p</i> Cu 800 GeV

⁶ This is our calculation from the MORELOS 93 measurements of the  $\Sigma^+$  and  $\overline{\Sigma}^-$  magnetic moments given above. The statistical error on  $\mu_{\overline{\Sigma}^-}$  dominates the error here.

### $\Sigma^+$ DECAY MODES

	Mode	Fraction $(\Gamma_{\hat{I}}/\Gamma)$ Confidence leve
Γ ₁	$p\pi^0$	(51.57±0.30) %
$\Gamma_2$	$n\pi^+$	$(48.31 \pm 0.30) \%$
$\Gamma_3$	$p\gamma$	$(1.23\pm0.05)\times10^{-3}$
$\Gamma_4$	$n\pi^+\gamma$	[a] $(4.5 \pm 0.5) \times 10^{-4}$
$\Gamma_5$	$\Lambda e^+ \nu_e$	$(2.0 \pm 0.5) \times 10^{-5}$

# $\Delta S = \Delta Q$ (SQ) violating modes or $\Delta S = 1$ weak neutral current (S1) modes

[a] See the Particle Listings below for the pion momentum range used in this measurement.

#### CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2=7.7$  for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\left\langle \delta s_i \delta s_j \right\rangle/(\delta x_i \cdot \delta x_j),$  in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\rm total}.$  The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$\begin{array}{c|cccc} x_2 & -100 & \\ x_3 & 12 & -14 \\ \hline & x_1 & x_2 \end{array}$$

### **Σ**⁰ MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process  $\Lambda \to \Sigma^0$  in nuclear Coulomb fields. An alternative expression of the same information is the  $\Sigma^{0}$ - $\Lambda$  transition magnetic moment given in the following section. The relation is  $(\mu_{\Sigma}\Lambda/\mu_{N})^2$   $\tau=1.92951\times 10^{-19}$  s (see DEVLIN 86).

VALUE (10 ⁻²⁰ s)	DOCUMENT ID		TECN	COMMENT
7.4±0.7 OUR EVALUATION	Using $\mu_{\sum \Lambda}$ (see th	e abo	ve note	١.

### **Σ**- DECAY MODES

	Mode	Fraction $(\Gamma_{\tilde{I}}/\Gamma)$
Γ ₁	$n\pi$	(99.848±0.005) %
$\Gamma_2$	$n\pi^-\gamma$	[a] ( 4.6 $\pm 0.6$ ) $\times 10^{-4}$
$\Gamma_3$	$ne^-\overline{ u}_e$	$(1.017\pm0.034)\times10^{-3}$
$\Gamma_4$	n $\mu^-\overline{ u}_\mu$	$(4.5 \pm 0.4) \times 10^{-4}$
$\Gamma_5$	$\Lambda e^- \overline{ u}_e$	$(5.73 \pm 0.27) \times 10^{-5}$

[a] See the Particle Listings below for the pion momentum range used in this measurement.

### CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2$  = 8.7 for 13 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv$  $\Gamma_i/\Gamma_{
m total}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

### **Σ**- BRANCHING RATIOS

 $\Gamma(n\pi^-\gamma)/\Gamma(n\pi^-)$ 

 $\Gamma_2/\Gamma_1$ 

The  $\pi^+$  momentum cuts differ, so we do not average the results but simply use the latest value for the Summary Table.

 $g_A/g_V$  FOR  $\Sigma^- \to ne^-\overline{\nu}_e$ Measurements with fewer than 500 events have been omitted. Where necessary, signs Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. What is actually listed is  $|g_1/f_1 - 0.237g_2/f_1|$ . This reduces to  $g_A/g_V \equiv g_1(0)/f_1(0)$  on making the usual assumption that  $g_2 = 0$ . See also the note on HSUEH 88.

 $^{^{\}rm 6}\, {\rm The}\, {\rm sign}$  is, with our conventions, unambiguously positive. The value assumes, as usual, that  $g_2=0$ . If  $g_2$  is included in the fit, than (with our sign convention)  $g_2=-0.56\pm0.37$ , with a corresponding reduction of  $g_A/g_V$  to  $+0.20\pm0.08$ .

 $f_2(0)/f_1(0)$  FOR  $\Sigma^- \to ne^- \overline{\nu}_e$ The signs have been changed to be in accord with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

TRIPLE CORRELATION COEFFICIENT D for  $\Sigma^- \to ne^- \overline{\nu}_e$ The coefficient D of the term D  $\mathbf{P} \cdot (\mathbf{p}_e \times \mathbf{p}_{\nu})$  in the  $\Sigma^- \to ne^- \overline{\nu}$  decay angular distribution. A nonzero value would indicate a violation of time-reversal invariance.

VALUE

### $\Sigma$ (1385) $P_{13}$

$$I(J^P) = 1(\frac{3}{2}^+)$$
 Status: ***

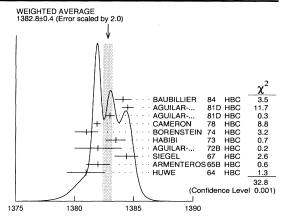

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** No. 2 Pt. II (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P-wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLM-GREN 77 obtains a good fit to their  $\Lambda\pi$  spectrum with a P-wave Breit-Wigner, but includes the partial width for the  $\Sigma\pi$  decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S-wave results are given here.

### Σ(1385) FOOTNOTES

- 1  From fit to inclusive  $\Lambda\pi$  spectrum.

- Includes data of HOLMGREN 77.

  3 The errors are statistical only. The resolution is not unfolded.

  4 The error is enlarged to  $\Gamma/\sqrt{N}$ . See the note on the  $K^*(892)$  mass in the 1984 edition.

  5 From a fit to  $\Lambda \pi^0$  with the width fixed at 34 MeV.

  From fit to inclusive  $\Lambda \pi^0$  spectrum with the width fixed at 40 MeV.

- 7 Redundant with data in the mass Listings.

  8 Results from  $\Lambda\pi^+\pi^-$  and  $\Lambda\pi^+\pi^-\pi^0$  combined by us.

  9 The error is enlarged to  $4\Gamma/\sqrt{N}$ . See the note on the  $K^*(892)$  mass in the 1984 edition.

  10 Consistent with +, 0, and widths equal.
- $^{11}\,\mathrm{An}$  extrapolation of the parametrized amplitude below threshold.

### $\Sigma$ (1480) Bumps

 $I(J^P) = 1(??)$  Status: *

#### OMITTED FROM SUMMARY TABLE

These are peaks seen in  $\Lambda\pi$  and  $\Sigma\pi$  spectra in the reaction  $\pi^+p\to$  $(Y\pi)K^+$  at 1.7 GeV/c. Also, the Y polarization oscillates in the samé region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of  $N(1675) \rightarrow \Lambda K$  decay. However, such an explanation for the  $(\Sigma^+\pi^0)K^+$  channel in terms of  $\Delta(1650) o \Sigma K$  decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the Y polarization in the 1480

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in  $K^-\,p\to~\Lambda\pi^0.$ 

ENGELEN 80 performs a multichannel analysis of  $K^- p \to p \overline{K}{}^0 \pi^$ at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in  $p\overline{K}^0$  which cannot be explained as a reflection of any competing channel.

## $\Sigma$ (1560) Bumps

 $I(J^P) = 1(?^?)$  Status: **

#### OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged  $\Lambda/\varSigma\pi$  mass spectra from  $K^-p\to (\Lambda/\varSigma)\pi\, K\, \overline{K}$  at 4.2 GeV/c. In a CERN ISR experiment, LOCK-MAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in  $\Lambda\pi^\pm$  from the reaction  $pp\to\Lambda\pi^+\pi^-X$ . These enhancements are unlikely to be associated with the  $\varSigma(1580)$  (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1  $\overline{K}$  N total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

#### $\Sigma$ (1580) FOOTNOTES

- ¹ CARROLL 76 sees a total-cross-section bump with  $(J+1/2) \Gamma_{el} / \Gamma_{total} = 0.06$ .
- ² The main effect observed by LITCHFIELD 74 is in the  $\Lambda\pi$  final state; the  $\overline{K}N$  and  $\Sigma\pi$  couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

### THE $\Sigma(1670)$ REGION

**Production experiments:** The measured  $\Sigma \pi / \Sigma \pi \pi$ branching ratio for the  $\Sigma(1670)$  produced in the reaction  $K^-p \to \pi^- \Sigma (1670)^+$  is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two  $\Sigma$  resonances with the same mass and quantum numbers: one with a large  $\Sigma\pi\pi$  (mainly  $\Lambda(1405)\pi$ ) branching fraction produced peripherally, and the other with a large  $\Sigma\pi$  branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the  $\Sigma\pi$  and the  $\Lambda(1405)\pi$  states are  $D_{13}$ . There is also possibly a third  $\Sigma$  in this region, the  $\Sigma(1690)$  in the Listings, the main evidence for which is a large  $\Lambda\pi/\Sigma\pi$  branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the  $\Sigma(1670)D_{13}$ , has the same quantum numbers as those observed in production and has a large  $\Sigma \pi / \Sigma \pi \pi$  branching ratio; it may well be the  $\Sigma(1670)$  produced at larger angles (see TIM-MERMANS 76). The other state, the  $\Sigma(1660)P_{11}$ , has different quantum numbers, its  $\Sigma \pi / \Sigma \pi \pi$  branching ratio is unknown, and its relation to the produced  $\Sigma(1670)$  states is obscure.

 $\Sigma(1670) D_{13}$ 

$$I(J^P) = 1(\frac{3}{2}^-)$$
 Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

Results from production experiments are listed separately in the next

#### Σ(1670) FOOTNOTES

- ¹ Total cross-section bump with (J+1/2)  $\Gamma_{el}$  /  $\Gamma_{total}$  = 0.23.
- ² Enhancements in  $\Sigma \pi$  and  $\Sigma \pi \pi$  cross sections. ³ Backward production in the  $\Lambda \pi^- K^+$  final state.
- Depending on production angle.

  A Depending on production angle.

  APSELL 74, ESTES 74, and TIMMERMANS 76 find strong branching ratio dependence on production angle, as in earlier production experiments.

## (PRODUCTION EXPERIMENTS)

- ¹ From  $\pi^+ p \rightarrow (\Lambda \pi^+) K^+$ . J > 1/2 is not required by the data.
- ² From  $\pi^+ p \rightarrow (\Lambda \pi^+)(K\pi)^+$ . J > 1/2 is indicated, but large background precludes a
- definite conclusion.  3  See the  $\Sigma(1670)$  Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the  $\Sigma(1690)$ .
- ⁴ This analysis, which is difficult and requires several assumptions and shows no unambiguous  $\Sigma(1690)$  signal, suggests  $J^P=5/2^+$ . Such a state would lead all previously known  $Y^*$  trajectories.

## $\Sigma(1750) S_{11}$

 $I(J^P) = 1(\frac{1}{2})$  Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to  $N\overline{K}$  and  $\Lambda\pi$ , as well as to  $\Sigma\eta$  whose threshold is at 1746 MeV (JONES 74).

## $\Sigma(1770) P_{11}$

 $I(J^P) = 1(\frac{1}{2}^+)$  Status: *

#### OMITTED FROM SUMMARY TABLE

Evidence for this state now rests solely on solution 1 of BAILLON 75, (see the footnotes) but the  $\Lambda\pi$  partial-wave amplitudes of this solution are in disagreement with amplitudes from most other  $\Lambda\pi$  analyses.

### $\Sigma$ (1770) FOOTNOTES

- 1  Required to fit the isospin-1 total cross section of CARROLL 76 in the  $\overline{K}\,N$  channel. The addition of new  $K^-p$  polarization and  $K^-n$  differential cross-section data in GOPAL 80 find it to be more consistent with the  $\Sigma(1660)$   $P_{11}$ .  2  From solution 1 of BAILLON 75; not present in solution 2.
- ³ Not required in KANE 74, which supersedes KANE 72.

 $\Sigma(1775) D_{15}$ 

$$I(J^P) = 1(\frac{5}{2}^-)$$
 Status: ***

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the  $\Lambda(1820)$  does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters 111B (1982).

#### Σ(1775) DECAY MODES

	Mode	Fraction $(\Gamma_i/\Gamma)$
$\overline{\Gamma_1}$	NK	37–43%
$\Gamma_2$	$\Lambda\pi$	14-20%
Гз	$\Sigma \pi$	2-5%
$\Gamma_4$	$\Sigma(1385)\pi$	8-12%
$\Gamma_5$	$\Sigma(1385)\pi$ , <i>D</i> -wave	
$\Gamma_6$	$\Lambda(1520)\pi$	17-23%
$\Gamma_7$	$\Sigma \pi \pi$	

The above branching fractions are our estimates, not fits or averages.

#### CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2$  = 63.9 for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv$  $\Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to

#### Σ(1775) BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on  $\varLambda$  and  $\varSigma$ Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too  $% \left\{ 1\right\} =\left\{

### $\Sigma$ (1775) FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- The two MARTIN // Values are from a 1-matrix pole and from a preti-viginer in.

  This rate combines P-wave- and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are -0.303 ± 0.010 and -0.037 ± 0.014. The published signs have been changed here to be in accord with the baryon-first convention.

  The CAMERON 78 upper limit on G-wave decay is 0.03.
- For about 3/4 of this, the  $\Sigma\pi$  system has I=0 and is almost entirely  $\Lambda(1520)$ . For the rest, the  $\Sigma\pi$  has I=1, which is about what is expected from the known  $\Sigma(1775) \to \Sigma(1385)\pi$  rate, as seen in  $\Lambda\pi\pi$ .

### $\Sigma$ (1880) FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
   ² From solution 1 of BAILLON 75; not present in solution 2.
   ³ Only unconstrained states from table 1 of LEA 73 are listed.
   ⁴ The published sign has been changed to be in accord with the baryon-first convention.

## $\Sigma$ (1915) $F_{15}$

$$I(J^P) = 1(\frac{5}{2}^+)$$
 Status: ***

Discovered by COOL 66. For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters 111B (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions in this region used to be listed in in a separate entry immediately following. They may be found in our 1986 edition Physics Letters 170B (1986).

### $\Sigma$ (1915) FOOTNOTES

- 1  The two entries for CORDEN 77C are from two different acceptable solutions.
- ² Preferred solution 3; see CORDEN 76 for other possibilities.
- 3 The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
  4 The mass and width are fixed to the GOPAL 77 values due to the low elasticity.

## $\Sigma(2030) F_{17}$

 $I(J^P) = 1(\frac{7}{2}^+)$  Status: ***

Discovered by COOL 66 and by WOHL 66. For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions around 2030 MeV may be found in our 1984 edition, Reviews of Modern Physics **56** No. 2 Pt. II (1984).

#### $\Sigma$ (2030) FOOTNOTES

- 1 Preferred solution 3; see CORDEN 76 for other possibilities.
  2 The two entries for CORDEN 77c are from two different acceptable solutions.
- ³ This coupling is extracted from unnormalized data.
- This coupling is extracted from uniformatical uses.

  4 The published sign has been changed to be in accord with the baryon-first convention.

  5 An upper limit.
- ⁶ The upper limit on the  $G_3$  wave is 0.03.

## $\Sigma(2070) F_{15}$

 $I(J^P) = 1(\frac{5}{2}^+)$  Status: *

### OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 with new  $K^-p$  polarization and  $K^-n$  angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of  $\overline{K}N \to \Sigma \pi$ .

 $\Sigma$ (2250)

$$I(J^P) = 1(??)$$
 Status: ***

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in  $\overline{K}N$  using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of  $\overline{K}N \to \Lambda\pi$ ,  $\Sigma\pi$ , and  $N\overline{K}$ , respectively, suggest two resonances around this mass.

 $I(J^P) = 1(??)$  Status: *

#### OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction  $K^-p \rightarrow Y^{*+}\pi^-$  using data from independent high statistics bubble chamber experiments at 8.25 and  $6.5~{
m GeV}/c$ . The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a  $K^-p$  experiment in LASS at 11 GeV/c (ASTON 85B).

### $\Xi$ 's, $\Xi$ (1530)

### **E** RESONANCES

The accompanying table gives our evaluation of the present status of the  $\Xi$  resonances. Not much is known about  $\Xi$ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few  $\mu$ b), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about  $\Xi$ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, there has not been a single new piece of data on  $\Xi$ resonances since our 1988 edition.

For a detailed earlier review, see Meadows [1].

#### Reference

$\Xi(1950)$		***	**	**		*		
$\Xi(2030)$	1	***		**	***			
$\Xi(2120)$		*		*				
$\Xi(2250)$		**					3-body decays	
$\Xi(2370)$	1	**					3-body decays	
$\Xi(2500)$		*		*	*		3-body decays	

- Existence is certain, and properties are at least fairly well explored. Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

  Evidence of existence is only fair.
- Evidence of existence is poor

## $\Xi(1530) P_{13}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$$
 Status: ***

This is the only  $\Xi$  resonance whose properties are all reasonably well known. Spin-parity  $3/2^+$  is favored by the data.

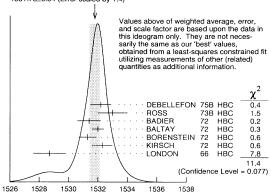

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

## $\Xi$ (1620)

 $I(J^P) = \frac{1}{2}(??)$  Status: * J, P need confirmation.

#### OMITTED FROM SUMMARY TABLE

What little evidence there is consists of weak signals in the  $\Xi\pi$ channel. A number of other experiments (e.g., BORENSTEIN 72 and HASSALL 81) have looked for but not seen any effect.

 $I(J^P) = \frac{1}{2}(??)$  Status: ***

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged  $\Sigma \overline{K}$  mass spectra in  $K^- p \rightarrow (\Sigma \overline{K}) K \pi$  at 4.2 GeV/c. The data from the  $\Sigma \overline{K}$  channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding  $\Lambda\overline{K}$  channels, and a coupled-channel analysis yields results consistent with a new  $\varXi.$ 

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced  $\Lambda K^-$  system. A peak is also observed in the  $\Lambda \overline{K}^0$  mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to  $\Sigma^0 \overline{K}{}^0$ , with the  $\gamma$  from the  $\Sigma^0$  decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of  $\Xi^-$  into  $\Lambda K^-$ . The significance claimed is 6.7 standard deviations.

 $\Xi(1820) D_{13}$ 

 $I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$  Status: ***

The clearest evidence is an 8-standard-deviation peak in  $\Lambda K^-$  seen by GAY 76. TEODORO 78 favors J=3/2, but cannot make a parity discrimination. BIAGI 87C is consistent with J=3/2 and favors negative parity for this J value.

### ≡(1820) MASS

#### **Ξ(1820) FOOTNOTES**

- 1  BIAGI 87 also sees weak signals in the in the  $\Xi^-\,\pi^+\,\pi^-$  channel at 1782.6  $\pm$  1.4 MeV ( $\Gamma=6.0\pm1.5$  MeV) and 1831.9  $\pm$  2.8 MeV ( $\Gamma=9.6\pm9.9$  MeV).
- (1 = 6.0  $\pm$  1.5 MeV) and 1531.9  $\pm$  2.6 MeV (1 = 5.0  $\pm$  9.7 MeV).

  2 BADIER 72 adds all channels and divides the peak into lower and higher mass regions. The data can also be fitted with a single Breit-Wigner of mass 1800 MeV and width 150 MeV.

  3 From a fit to inclusive  $\pm \pi$ ,  $\pm \pi$ , and  $\Lambda K^-$  spectra.
- ⁴ From a fit to inclusive  $\Xi\pi$  and  $\Xi\pi\pi$  spectra only. ⁵ Including  $\Xi\pi\pi$ .

- 6 DAUBER 69 uses in part the same data as SMITH 65c. 7 For the decay mode  $\Xi^-\pi^+\pi^0$  only. This limit includes  $\Xi(1530)\pi$ . 8 Or less. Upper limit for the 3-body decay.

## $\Xi(1950)$

$$I(J^P) = \frac{1}{2}(?^?)$$
 Status: ***

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a  $\Xi$  near 1950 MeV seems strong enough to include a  $\Xi(1950)$  in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one  $\Xi$ near this mass.

## $\Xi(2030)$

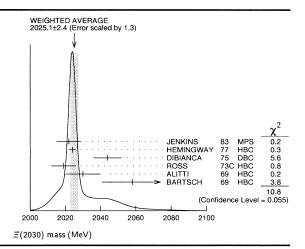

$$I(J^P) = \frac{1}{2}(\geq \frac{5}{2}?)$$
 Status: ***

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in  $\Sigma \overline{K}$  and a weaker coupling to  $\Lambda \overline{K}$ . ALITTI 68 and HEMINGWAY 77 observe no signals in the  $\Xi \pi \pi$  (or  $\Xi(1530)\pi$ ) channel, in contrast to DIBIANCA 75. The decay  $(\Lambda/\Sigma)\overline{K}\pi$  reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

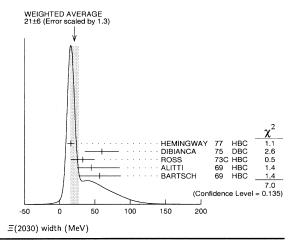

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that  $J \geq 5/2$ .

三(2250)

 $I(J^P) = \frac{1}{2}(?^?)$  Status: ** J, P need confirmation.

#### OMITTED FROM SUMMARY TABLE

The evidence for this state is mixed. BARTSCH 69 sees a bump of not much statistical significance in  $\Lambda \overline{K} \pi$ ,  $\Sigma \overline{K} \pi$ , and  $\Xi \pi \pi$  mass spectra. GOLDWASSER 70 sees a narrower bump in  $\Xi\pi\pi$  at a higher mass. Not seen by HASSALL 81 with 45 events/ $\mu$ b at 6.5  ${\rm GeV}/c$ . Seen by JENKINS 83. Perhaps seen by BIAGI 87.

² GAY 76c sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u. This suggests an anomalous production mechanism if the  $\Xi(2120)$  is real.

 $\Xi(2370), \Xi(2500)$

 $^{^{1}\,\}mathrm{KINSON}$  80 is a reanalysis of AMIRZADEH 80 with 50% more events.

## $\Omega$ BARYONS (S=-3, I=0)

 $\Omega^- = sss$ 

$$I(J^P) = O(\frac{3}{2}^+)$$
 Status: ***

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers have not actually been measured, but follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out J=1/2 and find consistency with J=3/2.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

#### $\Omega^-$ MASS

The fit assumes the  $\Omega^-$  and  $\overline{\Omega}^+$  masses are the same.

VALUE (MeV) 1672.45±0.29 OUR FIT	EVTS	DOCUMENT ID		TECN	COMMENT

1615	1	⁴ EISENBERG	54	EMUL	

- $^{1}\,\mathsf{DIBIANCA}$  75 gives a mass for each event. We quote the average.
- 2  The FRY 55 and FRY 558 events were identified as  $\Omega^-$  by ALVAREZ 73. The masses ² The FRY 55 and FRY 55s events were identified as  $\Omega^-$  by ALVAREZ 73. The masses assume decay to  $\Lambda K^-$  at rest. For FRY 55s, decay from an atomic orbit could Doppler shift the  $K^-$  energy and the resulting  $\Omega^-$  mass by several MeV. This shift is negligible for FRY 55 because the  $\Omega$  decay is approximately perpendicular to its orbital velocity, as is known because the  $\Lambda$  strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital  $\Omega$  is 4 or larger.

  ³ Excluded from the average; the  $\Omega^-$  lifetimes measured by the experiments differ significantly from other measurements.
- The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the  $\Omega$  interacted with an Ag nucleus to give  $K^- \Xi Ag$ .

### $\overline{\Omega}^+$ MASS

## $\Omega(2470)^{-1}$

Status: **

### OMITTED FROM SUMMARY TABLE

A peak in the  $\Omega^-\pi^+\pi^-$  mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

# CHARMED BARYONS (C = +1)

#### CHARMED BARYONS

Figure 1 shows the SU(4) multiplets that have as their lowest levels (a) the SU(3) octet that contains the nucleon, and (b) the SU(3) decuplet that contains the  $\Delta(1232)$ . All the particles in a given SU(4) multiplet have the same spin and parity. The only known charmed baryons each contain one charmed quark and thus belong to the second level of an SU(4) multiplet. Figure 2 shows this level for the SU(4) multiplet of Fig. 1(a). The level splits apart into two SU(3) multiplets, a  $\overline{3}$  that contains the  $\Lambda_c(2285)$  and the  $\Xi_c(2470)$ , both of which decay weakly, and a 6 that contains the  $\Sigma_c(2455)$ , which decays strongly to  $\Lambda_c \pi$ , and the  $\Omega_c(2710)$ , which decays weakly. A second  $\Xi_c$  remains to be discovered to fill out the 6, and a host of other baryons with one or more charmed quarks are needed to fill out the full SU(4) multiplets. Furthermore, every N or  $\Delta$  baryon resonance "starts" another SU(4) multiplet, so the woods are full of charmed baryons, most of which no doubt will forever remain undiscovered. The only candidates so far to belong to more massive multiplets are the  $\Lambda_c(2593)$  and the  $\Lambda_c(2625)$ , and perhaps a  $\Xi_c(2645)$ ; see the Listings.

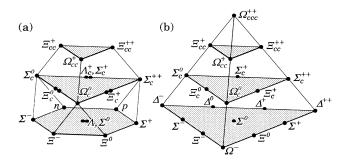

Fig. 1. SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet on the lowest level. (b) The 20-plet with an SU(3) decuplet on the lowest level.

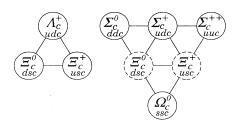

Fig. 2. The SU(3) multiplets on the second level of the SU(4) multiplet of Fig. 1(a). The particles in dashed circles have yet to be discovered.

The states of the  $\overline{\bf 3}$  multiplet in Fig. 2 are antisymmetric under interchange of the two light quarks (the u, d, and s quarks), whereas the states of the  $\bf 6$  multiplet are symmetric under interchange of these quarks. Actually, there may be some mixing between the pure  $\overline{\bf 3}$  and  $\bf 6$   $\Xi_c$  states (they have the same I,J, and P quantum numbers) to form the physical  $\Xi_c$  states.

It need hardly be said that the flavor symmetries Fig. 1 displays are very badly broken, but the figure is the simplest way to see what charmed baryons should exist.

For a review of theory and experiment, see Ref. 1.

#### References

 J.G. Körner, M. Krämer, and D. Pirjol, Prog. in Part. Nucl. Phys. 33, 787 (1994).

$$I(J^P) = 0(\frac{1}{2}^+)$$
 Status: ***

J has not actually been measured yet. Results of an analysis of  $pK^-\pi^+$  decays (JEZABEK 92) are consistent with the expected J=1/2. The quark content is udc.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

### 1 MASS

Measurements with an error greater than 5 MeV or that are otherwise obsolete have been omitted.

The fit also uses  $\Sigma_c - \Lambda_c^+$  and  $\Lambda_c^{*+} - \Lambda_c^+$  mass-difference measurements.

 $\Gamma_{60}$  dummy mode used by the fit (92.7  $\pm$  1.0 ) %

- [a] This branching fraction includes all the decay modes of the final-state resonance.
- [b]  $\ell$  indicates e or  $\mu$  mode, not sum over modes.
- [c] The value is for the sum of the charge states of particle/antiparticle states indicated

#### CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 9 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2=2.0$  for 7 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\left\langle \delta s_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j),$  in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\rm total}.$  The fit constrains the  $x_i$  whose labels appear in this array to sum to one

$$\begin{array}{c|cccc} x_{24} & 61 & \\ x_{60} & -90 & -89 \\ \hline & x_2 & x_{24} \end{array}$$

#### A+ BRANCHING RATIOS

Most of the modes are measured relative to the  $pK^-\pi^+$  mode. A few obsolete results have been omitted.

- >0.044 90 6  5  AGUILAR-... 888 LEBC pp 27.4 GeV  1  BERGFELD 94 measures  $\Gamma(pK^-\pi^+)/\Gamma(\Lambda\ell^+\nu_\ell)=1.93\pm0.10\pm0.33$  and calculates  $\Gamma(e^+$  anything)/ $\Gamma_{\rm total}=0.034\pm0.004$  from D-meson data, assuming that all charmed hadrons have the same semileptonic width. Combined, these values give  $\Gamma(pK^-\pi^+)/\Gamma_{\rm total}=f\times(6.67\pm0.35\pm1.35)\%$ , where  $f\equiv\Gamma(\Lambda\ell^+\nu_\ell)/\Gamma(\ell^+$  anything). Since  $f\leq 1$ , this gives an upper bound on  $\Gamma(pK^-\pi^+)/\Gamma_{\rm total}$ . In the spectator model, the quantity corresponding to f in D-meson decay is  $\Gamma(D\to(\overline{K}+\overline{K}^*)\ell^+\nu_\ell)/\Gamma(D\to\ell^+$  anything) = 0.89  $\pm$  0.12. This value of f leads to the value of  $\Gamma(pK^-\pi^+)/\Gamma_{\rm total}$  we give here.
- ² ALBRECHT 920 uses B( $\overline{B} \to \Lambda_c^+ X$ )×B( $\Lambda_c^+ \to \rho K^- \pi^+$ ) = (0.28  $\pm$  0.05)% plus B( $\overline{B} \to \Lambda_c^+ X$ ) = (6.8  $\pm$  0.5  $\pm$  0.3)% and assumes that  $\overline{B} \to \Xi_c X$  and  $\overline{B} \to \Omega_c X$  decays are suppressed and negligible.
- 3  CRAWFORD 92 uses B(\$\overline{B}\to \Lambda_c^+ X)\times B(\Lambda_c^+\to pK^-\pi^+)=(0.273\pm 0.051\pm 0.039)\% and estimates B(\$\overline{B}\$\to \$\Lambda_c^+ X)=(6.4\pm 0.8\pm 0.8)\%. If final states other than \$\Lambda_c^+ \overline{N}\$X contribute to \$\overline{B}\$ decay, the \$\Lambda_c^+\to pK^-\pi^+\$ branching fraction would increase.
- ⁴ ALBRECHT 88E uses their result B( $\overline{B} \to \Lambda_c^+ X$ )×B( $\Lambda_c^+ \to p K^- \pi^+$ ) = (0.30 ± 0.12 ± 0.06)% plus B( $\overline{B} \to \Lambda_c^+ X$ ) = (7.4 ± 2.9)% from other measurements of inclusive proton and  $\Lambda$  yields in B decays.
- 5  This AGUILAR-BENITEZ 888 limit assumes that  $\tau_{A_c}=1.2\times 10^{-13}$  s, and it "decreases by 20% [to > 0.035] assuming a lifetime of 1.7  $\times$  10  $^{-13}$  s instead." Our average for  $\tau_{A_c}$  is still higher (see the mean-life section), which would further reduce the limit.

 12  BISHAI 95 actually gives  $\alpha{=}-0.94^{+}_{-}0.21^{+}_{-}0.12^{}$ , chopping the errors at the physical limit -1.0. However, for  $\alpha\approx-1.0$ , some experiments should get unphysical values ( $\alpha<-1.0$ ), and for averaging with other measurements such values (or errors that extend below -1.0) should not be chopped.

### $\alpha$ FOR $\Lambda_c^+ \to \Sigma^+ \pi^0$

VALUE	<b>EVTS</b>	DOCUMENT ID	TECN	COMMENT	
$-0.45\pm0.31\pm0.06$	89	BISHAI 95	CLEO	$e^+e^-pprox \ \varUpsilon(4S)$	ı

### $\alpha$ FOR $\Lambda_c^+ \rightarrow \Lambda \ell^+ \nu_\ell$

The experiments don't cover the complete (or same incomplete)  $M(\Lambda \ell^+)$  range, but we average them together anyway.

## $\Lambda_c(2593)^+$

ı

ı

$$I(J^P) = O(\frac{1}{2})$$
 Status: ***

Seen in  $\Lambda_c^+\pi^+\pi^-$  but not in  $\Lambda_c^+\pi^0$ , so this is indeed an excited  $\Lambda_c^+$  rather than a  $\Sigma_c^+$ . The  $\Lambda_c^+\pi^+\pi^-$  mode is largely, and perhaps entirely,  $\Sigma_c\pi$ , which is just at threshold; thus (assuming, as has not yet been proven, that the  $\Sigma_c$  has  $J^P=1/2^+$ ) the  $J^P$  here is almost certainly  $1/2^-$ . This result is in accord with the theoretical expectation that this is the charm counterpart of the strange  $\Lambda(1405)$ .

### $\Lambda_c(2593)^+$ MASS

The value is obtained from the  $m_{\Lambda_c(2593)^+}-m_{\Lambda_c^+}$  mass-difference measurement below.

<u>VALUE (MeV)</u> <u>DOCUMENT ID</u> **2593.6±1.0 OUR FIT** Error includes scale factor of 1.2.

## $\Sigma_c(2455)$

$$I(J^P) = 1(\frac{1}{2}^+)$$
 Status: ***

 $J^P$  is not confirmed.  $1/2^+$  is the quark model prediction.

### $\Sigma_c$ (2455) MASSES

The mass measurements in this section are redundant with the mass difference measurements that follow. We get the masses by adding  $m_{\Sigma_c}(2455)-m_{\Lambda_c^+}$  to the  $\Lambda_c^+$  mass.

2459 ± 5 ±30	56	¹ COTEUS	87 S	PEC	nA ≃ 600 GeV
2460 ±25	82	BIAGI	83 S	PEC	Σ – Be 135 GeV

 1  Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the  $^{\prime}$  Kr $^{\prime}$   $^{\prime}$   $^{\prime}$  mass spectrum. COTEUS 87 sees  $\it two$  peaks in the same spectrum, one at the  $\it \Xi ^+_{\it c}$  mass, the other 75 MeV lower. The latter is attributed to  $\Xi_c^+ \to \Sigma^0 K^- \pi^+ \pi^+ \to (\Lambda \gamma) K^- \pi^+ \pi^+$ , with the  $\gamma$  unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

 $I(J^P) = ?(?^?)$  Status: ***

A narrow peak seen in the  $\Xi_c^+\pi^-$  mass spectrum. The natural assignment is that this is the  $J^P=3/2^+$  excitation of the  $\Xi_c$  in the same SU(4) multiplet as the  $\Delta$ (1232). We advance this to the Summary Table since it has also been seen by CLEO in  $\Xi_c^0 \pi^+$ (CLNS 96/1394, submitted but not yet approved, so not reported

 1  ALBAJAR 91E claims 16  $\pm$  5 events above a background of 9  $\pm$  1 events, a significance

Table Jan 18 to Earlins 1 as a svents above a background of 9  $\pm$  1 events, a significance of about 5 standard deviations. ABE 93B states that, based on the signal claimed by ALBAJAR 91E, CDF should have found 30  $\pm$  23  $\Lambda_D^0 \rightarrow J/\psi(1.5)\Lambda$  events. Instead, CDF found not more than 2 events. 3 The decay of the  $\Lambda_D^0$  to the final state observed by ARENTON 86 is Cabibbo suppressed,

whereas the decay of a  $\Xi_{b}^{0}$  to this final state is allowed. ARENTON 86 thus only claims to have observed a baryon which probably has a b quark and has a  $D^0$  among the decay products, not necessarily the  $\Lambda_b^0$ .

 4  The first claim to have discovered the  $\varLambda_b^0$  was reported by BASILE 81. In contrast, DRIJARD 82 reported no observation of  $\Lambda_b^0$ , and this led to some discussion in BASILE 82 and DRIJARD 82B. Further evidence for the  $\Lambda_b^0$  was again reported by the first authors in BARI 91 (see above) in a second, upgraded experiment where two different  $\Lambda_h^0$  decay

#### 18 MEAN LIFE

These are actually measurements of the average lifetime of weakly decaying  $\boldsymbol{b}$  baryons weighted by generally unknown production rates, branching fractions, and detection efficiencies. Presumably, the mix is mainly  $\Lambda_b^0$ with some  $\Xi_b^0$  and  $\Xi_b^-$ 

"OUR EVALUATION" is an average of the data listed below performed by the LEP  ${\cal B}$  Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the  ${\cal B}^\pm$  Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

#### AD DECAY MODES

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates in Z decay (or high-energy  $p\overline{p}$ ), branching ratios, and detection efficiencies. They scale with the LEP  $\Lambda_b$  production fraction B( $b \rightarrow \Lambda_b$ ) and are evaluated for our value B( $b \rightarrow$  $\Lambda_b^{-}$ ) = (13.2 ± 4.1)%.

The branching fractions B( $\varLambda_b^0 \to \Lambda \ell^- \overline{\nu}_\ell$  anything) and B( $\varLambda_b^0 \to$  $\Lambda_{c}^{+}\ell^{-}\overline{\nu}_{\ell}$  anything) are not pure measurements because the underlying measured products of these with B( $b\to\Lambda_b$ ) were used to determine B( $b\to\Lambda_b$ ), as described in the note "Production and Decay of b-Flavored

	Mode	Fraction $(\Gamma_i/\Gamma)$	
$\overline{\Gamma_1}$	$J/\psi(1S)\Lambda$	( 1.4 ± 0.9) %

ABREU

95V ZPHY C68 541

 $I(J^P) = O(\frac{1}{2}^+)$  Status: *

OMITTED FROM SUMMARY TABLE

ABREU 95V observe an excess of same-sign  $\varXi^\mp\ell^\mp$  events in jets, which they interpret as  $\Xi_b \to \Xi^- \ell^- \overline{\nu}_\ell X$ . They find that the probability for these events to come from non-b-baryon decays is less than 5  $\times$  10  $^{-4}$  and that  $\varLambda_b$  decays can account for less than 10%

In the quark model,  $\Xi_b^0$  and  $\Xi_b^-$  are an isodoublet (usb, dsb) state; the lowest  $\Xi_b^0$  and  $\Xi_b^-$  ought to have  $J^P=1/2^+$ . None of I, J, or P have actually been measured.

#### Ξ_b MEAN LIFE

This is actually a measurement of the average lifetime of b-baryons that decay to a jet containing a same-sign  $\varXi^\mp\ell^\mp$  pair. Presumably the mix is mainly  $\Xi_b$ , with some  $\Lambda_b$ .

#### MAGNETIC MONOPOLE SEARCHES

(by W.P. Trower, Virginia Polytechnic Institute and State University)

Although the usual formulation of Maxwell's equations suggests magnetic monopoles, no observed phenomenon requires them for explanation [1]. A monopole anywhere in the universe results in electric charge quantization everywhere, and leads to the prediction of a least magnetic charge  $G = e/2\alpha$ , the Dirac charge [2]. Recently monopoles have become indispensable in many gauge theories, which endow them with a variety of extraordinarily large masses.

Monopole detectors have predominantly used either induction or ionization. Induction experiments measure the monopole magnetic charge and are independent of monopole electric charge, mass, and velocity. Monopole candidate events (CABRERA 82, CAPLIN 86) in single semiconductor loops have been detected by this method, but no two-loop coincidence has been observed. Ionization experiments rely on a magnetic charge producing more ionization than an electrical charge with the same velocity. However, the ability to distinguish a monopole by ionization diminishes with velocity.

Cosmic rays are the most likely source of massive monopoles, since accelerator energies are insufficient to produce them. Evidence for such monopoles may also be obtained from astrophysical observations.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative.

  5 AHLEN 94 limit for dyons extends down to  $\beta$ =0.9E-4 and a limit of 1.3E-14 extends to  $\beta$  = 0.8E-4. Aso see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. New electronics will remove this possibility.
  6 Catalysis of nucleon decay; sensitive to assumed catalysis cross section.
  7 ORITO 91 limits are functions of velocity. Lowest limits are given here.
  8 Used DKMPR mechanism and Penning effect.
  9 Assumes monopole attaches fermion nucleus.
  10 Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.
  11 Based on lack of high- energy solar neutrinos from catalysis in the sun.
  12 Anomalous long-range  $\alpha$  (⁴ He) tracks.
  13 CABRERA 82 candidate event has single Dirac charge within ±5%.
  14 ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

### Supersymmetric Particle Searches

#### SUPERSYMMETRY

(by H.E. Haber, Univ. of California, Santa Cruz)

A. Introduction: Supersymmetry is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa. It also provides a framework for the unification of particle physics and gravity, which takes place at an energy of order the Planck scale ( $\approx 10^{19}$ GeV) [1-3]. However, supersymmetry is clearly not an exact symmetry of nature, and therefore must be broken. In theories of "low-energy" supersymmetry, the effective scale of supersymmetry breaking is tied to the electroweak scale [4-6]. In this way, it is hoped that supersymmetry will ultimately explain the origin of the large hierarchy between the W and Zmasses and the Planck scale. At present, there are no unambiguous experimental results that require the existence of low-energy supersymmetry. However, if experimentation at future colliders uncovers evidence for supersymmetry, this would have a profound effect on the study of TeV-scale physics and the development of a more fundamental theory of mass and symmetry-breaking phenomena in particle physics.

B. Structure of the MSSM: The minimal supersymmetric extension of the Standard Model (MSSM) consists of taking the Standard Model and adding the corresponding supersymmetric partners [7]. In addition, the MSSM contains two hypercharge  $Y=\pm 1$  Higgs doublets, which is the minimal structure for the Higgs sector of an anomaly-free supersymmetric extension of the Standard Model. The supersymmetric structure of the theory also requires (at least) two Higgs doublets to generate mass for both "up"-type and "down"-type quarks (and charged leptons) [8,9]. All renormalizable supersymmetric interactions consistent with (global) B-L conservation (B =baryon number and L =lepton number) are included. Finally, the most general soft-supersymmetry-breaking terms are added [10].

If supersymmetry is relevant for explaining the scale of electroweak interactions, then the mass parameters that occur in the soft-supersymmetry-breaking terms must be of order 1 TeV or below [11]. Some bounds on these parameters exist due to the absence of supersymmetric-particle production at current accelerators (see the Particle Listings following this note). Additional constraints arise from limits on the contributions of

virtual supersymmetric particle exchange to a variety of Standard Model processes [12]. The impact of precision electroweak measurements at LEP and SLC on the MSSM parameter space is discussed briefly at the end of this note.

As a consequence of B-L invariance, the MSSM possesses a discrete R-parity invariance, where  $R=(-1)^{3(B-L)+2S}$  for a particle of spin S [13]. Note that this formula implies that all the ordinary Standard Model particles have even R-parity, whereas the corresponding supersymmetric partners have odd R-parity. The conservation of R-parity in scattering and decay processes has a crucial impact on supersymmetric phenomenology. For example, starting from an initial state involving ordinary (R-even) particles, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay quickly into lighter states. However, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, the LSP is almost certainly electrically and color neutral [14]. Consequently, the LSP is weakly-interacting in ordinary matter, *i.e.* it behaves like a stable heavy neutrino and will escape detectors without being directly observed. Thus, the canonical signature for (*R*-parity conserving) supersymmetric theories is missing (transverse) energy, due to the escape of the LSP.

Some model builders attempt to relax the assumption of R-parity conservation. Models of this type must break B-L and are therefore strongly constrained by experiment [15]. Nevertheless, it is still important to allow for the possibility of R-parity violating processes in the search for supersymmetry. In such models, the LSP is unstable and supersymmetric particles can be singly produced and destroyed in association with B or L violation. These features lead to a phenomenology of broken-R-parity models that is very different from that of the MSSM.

In the MSSM, supersymmetry breaking is accomplished by including the soft-supersymmetry breaking terms mentioned earlier. These terms parametrize our ignorance of the fundamental mechanism of supersymmetry breaking. If this breaking occurs spontaneously, then (in the absence of supergravity) a massless Goldstone fermion called the goldstino  $(\tilde{G})$  must exist. The goldstino would then be the LSP and could play an important role in supersymmetric phenomenology [16]. In models that incorporate supergravity, this picture changes. If supergravity is spontaneously broken, the goldstino is absorbed ("eaten") by the gravitino  $(g_{3/2})$ , the spin-3/2 partner of the graviton [17]. By this super-Higgs mechanism, the gravitino acquires a mass  $(m_{3/2})$ . In many models, the gravitino mass is of order the electroweak-symmetry-breaking scale, while its couplings are gravitational in strength [1,18]. Such a gravitino would play no role in supersymmetric phenomenology at colliders.

#### Supersymmetric Particle Searches

The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving sector and the supersymmetry-breaking sector. A careful discussion of the conventions used in defining the MSSM parameters can be found in Ref. 19. Among the parameters of the supersymmetry conserving sector are: (i) gauge couplings:  $g_s$ , g, and g', corresponding to the Standard Model gauge group  $\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1)$  respectively; (ii) Higgs-Yukawa couplings:  $\lambda_e$ ,  $\lambda_u$ , and  $\lambda_d$  (which are  $3\times 3$  matrices in flavor space); and (iii) a supersymmetry-conserving Higgs mass parameter  $\mu$ .

The supersymmetry-breaking sector contains the following set of parameters: (i) gaugino Majorana masses  $M_3$ ,  $M_2$  and  $M_1$  associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) scalar mass matrices for the squarks and sleptons; (iii) Higgs-squark-squark trilinear interaction terms (the so-called "A-parameters") and corresponding terms involving the sleptons; and (iv) three scalar Higgs mass parameters—two diagonal and one off-diagonal mass terms for the two Higgs doublets. These three mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values,  $v_1$  and  $v_2$ , and one physical Higgs mass. Here,  $v_1$  ( $v_2$ ) is the vacuum expectation value of the Higgs field which couples exclusively to down-type (up-type) quarks and leptons. Note that  $v_1^2 + v_2^2 = (246 \text{ GeV})^2$  is fixed by the W mass (or equivalently by the Fermi constant  $G_F$ ), while the ratio

$$\tan \beta = v_2/v_1 \tag{1}$$

is a free parameter of the model.

The supersymmetric constraints imply that the MSSM Higgs sector is automatically CP-conserving (at tree-level). Thus,  $\tan\beta$  is a real parameter (conventionally chosen to be positive), and the physical neutral Higgs scalars are CP-eigenstates. Nevertheless, the MSSM does contain a number of possible new sources of CP violation. For example, gauginomass parameters, the A-parameters, and  $\mu$  may be complex. Some combination of these complex phases must be less than of order  $10^{-2}$ – $10^{-3}$  (for a supersymmetry-breaking scale of 100 GeV) to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [20]. However, these complex phases have little impact on the direct searches for supersymmetric particles, and are usually ignored in experimental analyses.

C. The Higgs sector of the MSSM: Before describing the supersymmetric-particle sector, let us consider the Higgs sector of the MSSM [21]. There are five physical Higgs particles in this model: a charged Higgs pair  $(H^{\pm})$ , two CP-even neutral Higgs bosons (denoted by  $H_1^0$  and  $H_2^0$  where  $m_{H_1^0} \leq m_{H_2^0}$ ) and one CP-odd neutral Higgs boson  $(A^0)$ . The properties of the Higgs sector are determined by the Higgs potential which is made up of quadratic terms [whose squared-mass coefficients were mentioned above Eq. (1)] and quartic interaction terms. The strengths of the interaction terms are directly related to the gauge couplings by supersymmetry (and are not affected

at tree-level by supersymmetry-breaking). As a result,  $\tan\beta$  [defined in Eq. (1)] and one Higgs mass determine: the Higgs spectrum, an angle  $\alpha$  [which indicates the amount of mixing of the original  $Y=\pm 1$  Higgs doublet states in the physical CP-even scalars], and the Higgs boson couplings.

When one-loop radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual loops. The impact of these corrections can be significant [22,23]. For example, at tree-level, the MSSM predicts  $m_{H_1^0} \leq m_Z$  [8,9]. If true, this would imply that experiments to be performed at LEP-2 operating at its maximum energy and luminosity would rule out the MSSM if  $H_1^0$  were not found. However, this Higgs mass bound can be violated when the radiative corrections are incorporated. For example, in Ref. 22, the following approximate upper bound was obtained for  $m_{H_1^0}$  (assuming  $m_{A^0} > m_Z$ ) in the limit of  $m_Z \ll m_t \ll M_{\widetilde{t}}$  [where top-squark  $(\widetilde{t}_L - \widetilde{t}_R)$  mixing is neglected]

$$\begin{split} m_{H_1^0}^2 \lesssim m_Z^2 + \frac{3g^2 m_Z^4}{16\pi^2 m_W^2} \\ &\times \left\{ \ln \left( \frac{M_t^2}{m_t^2} \right) \left[ \frac{2m_t^4 - m_t^2 m_Z^2}{m_Z^4} \right] + \frac{m_t^2}{3m_Z^2} \right\}. \end{split} \tag{2}$$

More refined computations (which include the effects of top-squark mixing, renormalization group improvement, and the leading two-loop contributions) yield  $m_{H_1^0} \lesssim 125$  GeV for  $m_t = 175$  GeV and a top-squark mass of  $M_{\widetilde{t}} = 1$  TeV [24]. Clearly, the radiative corrections to the Higgs masses have a significant impact on the search for the Higgs bosons of the MSSM at LEP [25].

D. Supersymmetric-particle spectrum: Consider next the supersymmetric-particle sector of the MSSM. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" at the end of the corresponding Standard Model particle name. The gluino is the color octet Majorana fermion partner of the gluon with mass  $M_{\widetilde{g}} = |M_3|$ . The supersymmetric partners of the electroweak gauge and Higgs bosons (the gauginos and Higgsinos) can mix. As a result, the physical mass eigenstates are model-dependent linear combinations of these states, called charginos and neutralinos, which are obtained by diagonalizing the corresponding mass matrices. The chargino-mass matrix depends on  $M_2$ ,  $\mu$ , tan  $\beta$  and  $m_W$  [26].

The corresponding chargino-mass eigenstates are denoted by  $\widetilde{\chi}_1^+$  and  $\widetilde{\chi}_2^+$ , with masses

$$M_{\widetilde{\chi}_{1}^{+},\widetilde{\chi}_{2}^{+}}^{2} = \frac{1}{2} \left\{ |\mu|^{2} + |M_{2}|^{2} + 2m_{W}^{2} \right.$$

$$\left. \mp \left[ \left( |\mu|^{2} + |M_{2}|^{2} + 2m_{W}^{2} \right)^{2} - 4|\mu|^{2} |M_{2}|^{2} \right.$$

$$\left. - 4m_{W}^{4} \sin^{2} 2\beta + 8m_{W}^{2} \sin 2\beta \operatorname{Re}(\mu M_{2}) \right]^{1/2} \right\}, (3)$$

where the states are ordered such that  $M_{\widetilde{\chi}_1^+} \leq M_{\widetilde{\chi}_2^+}$ . If CP-violating effects are ignored (in which case,  $M_2$  and  $\mu$  are real

parameters), then one can choose a convention where  $\tan \beta$  and  $M_2$  are positive. (Note that the relative sign of  $M_2$  and  $\mu$  is meaningful. The sign of  $\mu$  is convention-dependent; the reader is warned that both sign conventions appear in the literature.) The sign convention for  $\mu$  implicit in Eq. (3) is used by the LEP collaborations [27] in their plots of exclusion contours in the  $M_2$ vs.  $\mu$  plane derived from the non-observation of  $Z \to \widetilde{\chi}_1^+ \widetilde{\chi}_1^-$ . The neutralino mass matrix depends on  $M_1$ ,  $M_2$ ,  $\mu$ ,  $\tan \beta$ ,  $m_Z$ , and the weak mixing angle  $\theta_W$  [26]. The corresponding neutralino eigenstates are usually denoted by  $\widetilde{\chi}_{i}^{0}$   $(i=1,\ldots 4)$ , according to the convention that  $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$ . If a chargino or neutralino eigenstate approximates a particular gaugino or Higgsino state, it may be convenient to use the corresponding nomenclature. For example, if  $M_1$  and  $M_2$  are small compared to  $m_Z$  (and  $\mu$ ), then the lightest neutralino  $\tilde{\chi}_1^0$ will be nearly a pure photino,  $\tilde{\gamma}$  (the supersymmetric partner of the photon).

It is common practice in the literature to reduce the supersymmetric parameter freedom by requiring that all three gaugino-mass parameters are equal at some grand unification scale. Then, at the electroweak scale, the gaugino-mass parameters can be expressed in terms of one of them (say,  $M_2$ ). The other two gaugino-mass parameters are given by

$$M_3 = (g_s^2/g^2)M_2$$
,  $M_1 = (5g'^2/3g^2)M_2$ . (4)

Having made this assumption, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass,  $\mu$ , and  $\tan \beta$ . However, the assumption of gaugino-mass unification could prove false and must eventually be tested experimentally.

The supersymmetric partners of the quarks and leptons are spin-zero bosons: the squarks, charged sleptons, and sneutrinos. For a given fermion f, there are two supersymmetric partners  $\widetilde{f}_L$  and  $\widetilde{f}_R$  which are scalar partners of the corresponding left and right-handed fermion. (There is no  $\widetilde{\nu}_R$ .) However, in general,  $\widetilde{f}_L$  and  $\widetilde{f}_R$  are not mass-eigenstates since there is  $\widetilde{f}_L$ - $\widetilde{f}_R$  mixing which is proportional in strength to the corresponding element of the scalar mass-squared matrix [28]:

$$M_{LR}^2 = \begin{cases} m_d(A_d - \mu \tan \beta), & \text{for "down"-type } f \\ m_u(A_u - \mu \cot \beta), & \text{for "up"-type } f, \end{cases}$$
 (5)

where  $m_d$   $(m_u)$  is the mass of the appropriate "down" ("up") type quark or lepton. Here,  $A_d$  and  $A_u$  are (unknown) soft-supersymmetry-breaking A-parameters and  $\mu$  and  $\tan\beta$  have been defined earlier. The signs of the A parameters are also convention-dependent; see Ref. 19. Due to the appearance of the fermion mass in Eq. (5), one expects  $M_{LR}$  to be small compared to the diagonal squark and slepton masses, with the possible exception of the top-squark, since  $m_t$  is large, and the bottom-squark and tau-slepton if  $\tan\beta\gg 1$ .

The (diagonal) L- and R-type squark and slepton masses are given by [2]

$$M_{\widetilde{u}_I}^2 = M_{\widetilde{C}}^2 + m_u^2 + m_Z^2 \cos 2\beta (\frac{1}{2} - \frac{2}{3}\sin^2\theta_W)$$
 (6)

$$M_{\widetilde{\nu}_{R}}^{2} = M_{\widetilde{\nu}_{L}}^{2} + m_{u}^{2} + \frac{2}{3}m_{Z}^{2}\cos 2\beta \sin^{2}\theta_{W}$$
 (7)

$$M_{\widetilde{d}_L}^2 = M_{\widetilde{Q}}^2 + m_d^2 - m_Z^2 \cos 2\beta (\frac{1}{2} - \frac{1}{3}\sin^2\theta_W)$$
 (8)

$$M_{\widetilde{d}_{P}}^{2} = M_{\widetilde{P}}^{2} + m_{d}^{2} - \frac{1}{3}m_{Z}^{2}\cos 2\beta \sin^{2}\theta_{W}$$
 (9)

$$M_{\widetilde{\nu}}^2 = M_{\widetilde{L}}^2 + \frac{1}{2}m_Z^2 \cos 2\beta \tag{10}$$

$$M_{\widetilde{e_{I}}}^{2} = M_{\widetilde{I}}^{2} + m_{e}^{2} - m_{Z}^{2} \cos 2\beta (\frac{1}{2} - \sin^{2}\theta_{W})$$
 (11)

$$M_{\widetilde{e}_R}^2 = M_{\widetilde{E}}^2 + m_e^2 - m_Z^2 \cos 2\beta \sin^2 \theta_W \,.$$
 (12)

The soft-supersymmetry-breaking parameters:  $M_{\widetilde{Q}}$ ,  $M_{\widetilde{U}}$ ,  $M_{\widetilde{D}}$ ,  $M_{\widetilde{L}}$ , and  $M_{\widetilde{E}}$  are unknown parameters. In the equations above, the notation of first generation fermions has been used and generational indices have been suppressed. Further complications such as intergenerational mixing are possible, although there are some constraints from the nonobservation of flavor-changing neutral currents (FCNC) [29].

E. Reducing the MSSM parameter freedom: One way to guarantee the absence of significant FCNC's mediated by virtual supersymmetric-particle exchange is to posit that the diagonal soft-supersymmetry-breaking scalar squared-masses are universal in flavor space at some energy scale (normally taken to be at or near the Planck scale) [5,30,31]. Renormalization group evolution is used to determine the low-energy values for the scalar mass parameters listed above. This assumption substantially reduces the MSSM parameter freedom. For example, supersymmetric grand unified models with universal scalar masses at the Planck scale typically give [32]  $M_{\widetilde{L}} \approx M_{\widetilde{E}} < M_{\widetilde{O}} \approx$  $M_{\widetilde{I}I} \approx M_{\widetilde{D}}$  with the squark masses somewhere between a factor of 1-3 larger than the slepton masses (neglecting generational distinctions). More specifically, the first two generations are thought to be nearly degenerate in mass, while  $M_{\widetilde{O}_2}$  and  $M_{\widetilde{U}_2}$  are typically reduced by a factor of 1–3 from the other soft-supersymmetry-breaking masses because of renormalization effects due to the heavy top quark mass.

As a result, four flavors of squarks (with two squark eigenstates per flavor) and  $\widetilde{b}_R$  will be nearly mass-degenerate and somewhat heavier than six flavors of nearly mass-degenerate sleptons (with two per flavor for the charged sleptons and one per flavor for the sneutrinos). On the other hand, the  $\widetilde{b}_L$  mass and the diagonal  $\widetilde{t}_L$  and  $\widetilde{t}_R$  masses are reduced compared to the common squark mass of the first two generations. In addition, third generation squark masses and tau-slepton masses are sensitive to the strength of the respective  $\widetilde{f}_L - \widetilde{f}_R$  mixing as discussed below Eq. (5).

Two additional theoretical frameworks are often introduced to reduce further the MSSM parameter freedom [1,2,33]. The first involves grand unified theories (GUTs) and the desert

#### Supersymmetric Particle Searches

hypothesis (i.e no new physics between the TeV-scale and the GUT-scale). Perhaps one of the most compelling hints for lowenergy supersymmetry is the unification of  $SU(3) \times SU(2) \times U(1)$ gauge couplings predicted by supersymmetric GUT models [5,34] (with the supersymmetry breaking scale of order 1 TeV or below). The unification, which takes place at an energy scale of order 10¹⁶ GeV, is quite robust (and depends weakly on the details of the GUT-scale theory). For example, a recent analysis [35] finds that supersymmetric GUT unification implies that  $\alpha_s(m_Z) = 0.129 \pm 0.010$ , not including threshold corrections due to GUT-scale particles (which could diminish the value of  $\alpha_s(m_Z)$ ). This result is compatible with the world average of  $\alpha_s(m_Z) = 0.118 \pm 0.003$  as quoted by the Particle Data Group. In contrast, gauge coupling unification in the simplest nonsupersymmetric GUT models fails by many standard deviations [36].

Grand unification can impose additional constraints through the unification of Higgs-fermion Yukawa couplings  $(\lambda_f)$ . There is some evidence that  $\lambda_b = \lambda_\tau$  leads to good low-energy phenomenology [37], and an intriguing possibility that in the MSSM (in the parameter regime where  $\tan \beta \simeq m_t/m_b$ )  $\lambda_b = \lambda_\tau = \lambda_t$  may be phenomenologically viable [38]. However, such unification constraints are GUT-model dependent, and do not address the origin of the first and second generation fermion masses and the CKM mixing matrix. Finally, grand unification imposes constraints on the soft-supersymmetry-breaking parameters. For example, gaugino-mass unification leads to the relations given in Eq. (4). Diagonal squark and slepton soft-supersymmetry-breaking scalar masses may also be unified at the GUT scale (analogous to the unification of Higgs-fermion Yukawa couplings).

In order to further reduce the number of independent softsupersymmetry-breaking parameters (with or without grand unification), an additional simplifying assumption is required. In the minimal supergravity theory, the soft-supersymmetrybreaking parameters are often taken to have the following simple form. Referring to the parameter list given above Eq. (1), the Planck-scale values of the soft-supersymmetry-breaking terms depend on the following minimal set of parameters: (i) a universal gaugino mass  $m_{1/2}$ ; (ii) a universal diagonal scalarmass parameter  $m_0$  [whose consequences were described at the beginning of this section]; (iii) a universal A-parameter, A₀; and (iv) three scalar Higgs mass parameters—two common diagonal-squared masses given by  $|\mu_0|^2 + m_0^2$  and an off-diagonal-squared mass given by  $B_0\mu_0$  (which defines the Planck-scale supersymmetry-breaking parameter  $B_0$ ), where  $\mu_0$ is the Planck-scale value of the  $\mu$ -parameter.

As before, renormalization group evolution is used to compute the low-energy values of the supersymmetry-breaking parameters and determines the supersymmetric-particle spectrum. Moreover, in this approach, electroweak symmetry breaking is induced radiatively if one of the Higgs diagonal-squared masses is forced negative by the evolution. This occurs in models with a large Higgs-top quark Yukawa coupling  $(i.e. \text{ large } m_t)$ .

As a result, the two Higgs vacuum expectation values (or equivalently,  $m_Z$  and  $\tan \beta$ ) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure [32] is to remove  $\mu_0$  and  $B_0$  in favor of  $m_Z$  and  $\tan \beta$  (the sign of  $\mu_0$  is not fixed in this process). In this case, the MSSM spectrum and its interactions are determined by  $m_0$ ,  $A_0$ ,  $m_{1/2}$ ,  $\tan \beta$ , and the sign of  $\mu_0$  (in addition to the parameters of the Standard Model). However, the minimal approach above is probably too restrictive. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry breaking parameters is not generic [39]. In the absence of a fundamental theory of supersymmetry breaking, further progress will require a detailed knowledge of the supersymmetric-particle spectrum in order to determine the nature of the Planck-scale parameters. Of course, any of the theoretical assumptions described in this section could be wrong and must eventually be tested experimentally.

F. The MSSM and precision of electroweak data: The MSSM (with or without constraints imposed from the theory near the Planck scale) provides a framework that can be tested by precision electroweak data. The level of accuracy of the measured Z decay observables at LEP and SLC is sufficient to test the structure of the one-loop radiative corrections of the electroweak model [40], and is thus potentially sensitive to the virtual effects of undiscovered particles. Combining the most recent LEP and SLC electroweak results [41] with the recent topquark mass measurement at the Tevatron [42], a weak preference is found [41,43] for a light Higgs boson mass of order  $m_Z$ , which is consistent with the MSSM Higgs mass upper bound previously noted. Moreover, for Z decay observables, the effects of virtual supersymmetric-particle exchange are suppressed by a factor of  $m_Z^2/M_{\rm SUSY}^2$ , and therefore decouple in the limit of large supersymmetric-particle masses. It follows that for  $M_{\rm SUSY}^2 \gg$  $m_Z$  (in practice, it is sufficient to have all supersymmetricparticle masses above 200 GeV) the MSSM yields an equally good fit to the precision electroweak data as compared to the Standard Model fit.

On the other hand, there are a few tantalizing hints in the data for deviations from Standard Model predictions. Indeed, if  $R_b \equiv \Gamma(Z \to b\bar{b})/\Gamma(Z \to {\rm hadrons})$  is confirmed to lie above its Standard Model prediction due to the presence of new physics, then a plausible candidate for the new physics would be the MSSM with some light supersymmetric particles (e.g. a light chargino and top-squark and/or a light CP-odd scalar,  $A^0$ ) close in mass to their present LEP bounds [44,45]. Such a scenario would be tested by the search for supersymmetric particles at LEP-2 and the Tevatron.

G. Beyond the MSSM: Nonminimal versions of low-energy supersymmetry can also be constructed. These models add additional matter and/or gauge super-multiplets to the MSSM (at the TeV scale or below). Experimental and theoretical constraints place some restrictions on these approaches, although no comprehensive treatment has yet appeared in the literature.

#### MINIMAL SUPERSYMMETRIC STANDARD MODEL ASSUMPTIONS

All results shown below (except where stated otherwise) are based on the Minimal Supersymmetric Standard Model (MSSM) as described in the Note on Supersymmetry. This includes the assumption that *R*-parity is conserved. In addition the following assumptions are made in most cases:

- 1) The  $\tilde{\chi}^0_1$  (or  $\tilde{\gamma})$  is the lightest supersymmetric particle (LSP).
- 2)  $m_{\widetilde{f_L}}=m_{\widetilde{f_R}}$  where  $\widetilde{f_L}$  and  $\widetilde{f_R}$  refer to the scalar partners of left-and right-handed fermions.

Limits involving different assumptions either are identified with comments or are in the miscellaneous section.

When needed, specific assumptions of the eigenstate content  $\underbrace{\widetilde{o}}_{}^{}$  neutralinos and charginos are indicated (use of the notation  $\tilde{\gamma}$  (photino),  $\tilde{H}$  (Higgsino),  $\widetilde{W}$  (w-ino), and  $\widetilde{Z}$  (z-ino) indicates the approximation of a pure state was

#### $\widetilde{\chi}_{1}^{0}$ (Lightest Neutralino) MASS LIMIT

 $\widetilde{\chi}_1^0$  is likely to be the lightest supersymmetric particle (LSP). See also the  $\widetilde{\chi}_2^0$ ,  $\widetilde{\chi}_3^0$ ,  $\widetilde{\chi}_4^0$  section below.

We have divided the  $\tilde{\chi}^0_1$  listings below into three sections: 1) Accelerator limits for  $ilde{\chi}_1^0$ , 2) Bounds on  $ilde{\chi}_1^0$  from dark matter searches, and 3) Other bounds on  $ilde{\chi}_1^0$  from astrophysics and cosmology.

#### Accelerator limits for $\tilde{\chi}_1^0$

These papers generally exclude regions in the  $M_2-\mu$  parameter plane based on accelerator experiments. Unless otherwise stated, these papers assume minimal supersymmetry and GUT relations (gaugino-mass unification condition).

Bounds on  $\widetilde{\chi}_1^0$  from dark matter searches

These papers generally exclude regions in the  $M_2-\mu$  parameter plane assuming that  $\widetilde{\chi}^0_1$  is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments or by the absence of a signal in underground neturino detectors. The latter signal is expected if  $\widetilde{x}_1^0$  accumulates in the Sun or the Earth and annihilates into high-energy  $\nu$ 's.

- produced by energetic neutrinos from neutralino annihilation in the Sun and the Eartn.  9  BOTTINO 92 excludes some region  $M_{2^-\mu}$  parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling, Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.  10  BOTTINO 91 excluded a region in  $M_2-\mu$  plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson.  11  GFI.MINI 91 exclude a region in  $M_2-\mu$  plane using dark matter searches.
- 11 GELMINI 91 exclude a region in  $M_2-\mu$  plane using dark matter searches.
- 12  KAMIONKOWSKI 91 excludes a region in the  $M_2$ - $\mu$  plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that  $m_{H_1^0} \lesssim$  50 GeV. See Fig. 8
- 13  MORI 91B exclude a part of the region in the  $M_2$ – $\mu$  plane with  $m_{\widetilde{\chi}^0_1}\lesssim 80$  GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that  $m_{H_1^0} \lesssim 80$  GeV.
- 14  OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

#### Other bounds on $\widetilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the  $M_2$  -  $\mu$  parameter plane by requiring that the  $\tilde{\chi}^0_1$  contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

- 15  Mass of the bino (=LSP) is limited to  $m_{\widetilde{B}}\lesssim 350$  GeV for  $m_t=174$  GeV.  16  Mass of the bino (=LSP) is limited to  $m_{\widetilde{B}}\lesssim 350$  GeV for  $m_t\leq 200$  GeV. Mass of the higgsino (=LSP) is limited to  $m_{\widetilde{H}} \lesssim 1$  TeV for  $m_t \leq 200$  GeV.
- 17  Mass of the bino (=LSP) is limited to  $m_{\widetilde{B}} \lesssim$  550 GeV. Mass of the higgsino (=LSP) is limited to  $m_{\widetilde{H}} \lesssim$  3.2 TeV.
- 18  GRIFOLS 90 argues that SN1987A data exclude a light photino (  $\lesssim 1$  MeV) if  $m_{\widetilde{a}} < 1.1$ TeV,  $m_{\widetilde{e}}$  < 0.83 TeV.
- 19  ELLIS 888 argues that the observed neutrino flux from SN 1987A is inconsistent with a light photino if 60 GeV  $\lesssim m_{\widetilde{q}} \lesssim 2.5$  TeV. If  $m({\rm higgsino})$  is O(100 eV) the same argument leads to limits on the ratio of the two Higgs v.e.v.'s. LAU 93 discusses possible relations of ELLIS 88B bounds.
- $_{20}$  KRAUSS 83 finds  $m_{\widetilde{\gamma}}$  not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region  $m_{\widetilde{\gamma}}=$  4–20 MeV exists if  $m_{\rm gravitino}$  <40 TeV. See figure 2.

 $\widetilde{X}_{2}^{0}$ ,  $\widetilde{X}_{3}^{0}$ ,  $\widetilde{X}_{4}^{0}$  (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to  $\widetilde{X}_{2}^{0}$ ,  $\widetilde{X}_{3}^{0}$ , and  $\widetilde{X}_{4}^{0}$ .  $\widetilde{X}_{1}^{0}$  is the lightest supersymmetric particle (LSP); see  $\widetilde{X}_{1}^{0}$  Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various  $\widetilde{X}_{1}^{0}$  decay modes, on the masses of decay products  $(\widetilde{e}, \widetilde{\gamma}, \widetilde{q}, \widetilde{g})$ , and on the  $\widetilde{e}$  mass exchanged is  $(\widetilde{e}, \widetilde{\gamma}, \widetilde{q}, \widetilde{g})$ . The masses of decay products  $(\widetilde{e}, \widetilde{\gamma}, \widetilde{q}, \widetilde{g})$  and on the  $\widetilde{e}$  mass exchanged is  $(\widetilde{e}, \widetilde{q}, \widetilde{q}, \widetilde{g})$ . in  $e^+e^- o \widetilde{\chi}^0_i \widetilde{\chi}^0_i$ . Often limits are given as contour plots in the  $m_{\widetilde{\chi}0}-m_{\widetilde{e}}$  plane vs other parameters. When specific assumptions are made, e.g, the neutralino is a pure photino  $(\widetilde{\gamma})$ , pure z-ino  $(\widetilde{Z})$ , or pure neutral higgsino  $(\widetilde{H}^0)$ , the neutralinos will be labelled as such.

- 21  ACCIARRI 95E limits go down to 0 GeV  $(\widetilde{\chi}^0_2)$ , 60 GeV  $(\widetilde{\chi}^0_3)$ , and 90 GeV  $(\widetilde{\chi}^0_4)$  for  $\tan\!\beta=1$ .
- ²²ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on  $\sigma(\widetilde{X}_1^{\pm}\widetilde{X}_2^0) \times B(\widetilde{X}_1^{\pm} \rightarrow \ell\nu_\ell\widetilde{X}_1^0) \times B(\widetilde{X}_2^0 \rightarrow \ell^+\ell^-\widetilde{X}_2^0)$  as a function of  $m_{\widetilde{\chi}_1^0}$ . Limits range from 3.1 pb  $(m_{\widetilde{\chi}_1^0} = 45 \text{ GeV})$  to 0.6 pb  $(m_{\widetilde{\chi}_1^0} = 100 \text{ GeV})$ .
- ²³ For  $tan\beta > 2$  the limit is >40 GeV; and it disappears for  $tan\beta < 1.6$
- 24 HIDAKA 91 limit obtained from LEP and preliminary CDF limits on the gluino mass (as analyzed in BAER 91).
- ²⁵ABREU 90G exclude B( $Z \to \widetilde{\chi}_1^0 \widetilde{\chi}_2^0$ )  $\geq 10^{-3}$  and B( $Z \to \widetilde{\chi}_2^0 \widetilde{\chi}_2^0$ )  $\geq 2 \times 10^{-3}$ assuming  $\tilde{\chi}^0_2 \to \tilde{\chi}^0_1 f \overline{f}$  via virtual Z. These exclude certain regions in model parameter space, see their Fig. 5.
- space, see their rig. 5.  $26\,\mathrm{AKRAWY}$  90N exclude B( $Z \to \tilde{\chi}^0_1\tilde{\chi}^0_2$ )  $\gtrsim 3-5 \times 10^{-4}$  assuming  $\tilde{\chi}^0_2 \to \tilde{\chi}^0_1f\bar{f}$  or  $\tilde{\chi}^0_1\gamma^0_1f\bar{f}$  or  $\tilde{\chi}^0_1f\bar{f}$  or  $\tilde{\chi}^0_1f\bar{f}$
- 27  BAER 90 is independent of decay modes. Limit from analysis of supersymmetric parameter space restrictions implied by  $\Delta\Gamma(Z) < 120$  MeV. These result from decays of Z to all combinations of  $\tilde{\chi}_i^{\pm}$  and  $\tilde{\chi}_i^0$ . Minimal supersymmetry with  $\tan\beta>1$  is assumed.
- 28 See Figs. 4, 5 in BARKLOW 90 for the excluded regions.

  29 DECAMP 90κ exclude certain regions in model parameter space, see their figures.
- 30 SAKAI 90 assume  $m_{\widetilde{H}_1^0}=0$ . The limit is for  $m_{\widetilde{H}_2^0}$ .
- ³¹ Pure  $\tilde{\gamma}$  and pure  $\tilde{Z}$  eigenstates. B( $\tilde{Z} \to q \bar{q} \tilde{\gamma}$ ) = 0.60 and B( $\tilde{Z} \to e^+ e^- \tilde{\gamma}$ ) = 0.13.  $m_{\tilde{E}_l} = m_{\tilde{E}_R} < 70$  GeV.  $m_{\tilde{\gamma}} < 10$  GeV.
- ³² Pure higgsino. The LSP is the other higgsino and is taken massless. Limit degraded if  $\widetilde{\chi}^0$  not pure higgsino or if LSP not massless.
- 34 Pure  $\tilde{\gamma}$  and pure  $\tilde{Z}$  eigenstates. B( $\tilde{Z} \rightarrow \tilde{\nu}\nu$ ) = 1.  $m_{\tilde{e}_L} = m_{\tilde{e}_R} = 26$  GeV.  $m_{\tilde{\gamma}} = 10$ GeV. No excluded region remains for  $m_{\widetilde{e}}~>$ 30 GeV.
- 35 AKERLOF 85 is  $e^+e^-$  monojet search motivated by UA1 monojet events. Observed only one event consistent with  $e^+e^-\to \gamma+\tilde{\chi}^0$  where  $\tilde{\chi}^0\to$  monojet. Assuming that missing- $p_T$  is due to  $\tilde{\gamma}$ , and monojet due to  $\tilde{\chi}^0$ , limits dependent on the mixing and  $m_{\widetilde{e}}$  are given, see their figure 4.
- ³⁶BARTEL 85L assume  $m_{\widetilde{H}_1^0}=0$ ,  $\Gamma(Z o \widetilde{H}_1^0\widetilde{H}_2^0)\gtrsim rac{1}{2}\;\Gamma(Z o 
  u_e\overline{
  u}_e)$ . The limit is
- 37  BEHREND 85 find no monojet at  $E_{
  m cm}=$  40–46 GeV. Consider  $\widetilde{\chi}^0$  pair production via  $Z^0$ . One is assumed as massless and escapes detector. Limit is for the heavier one, decaying into a jet and massless  $\widetilde{\chi}^0$ . Both  $\widetilde{\chi}^0$ 's are assumed to be pure higgsino. For these very model-dependent results, BEHREND 85 excludes m=1.5–1.9.5 GeV.
- 38  ADEVA 84s observed no events with signature of acoplanar lepton pair with missing energy. Above example limit is for  $m_{\widetilde{\gamma}}$  <2 GeV and  $m_{\widetilde{e}}$  <40 GeV, and assumes
- B( $\widetilde{Z} \to \mu^+ \mu^- \widetilde{\gamma}) = B(\widetilde{Z} \to e^+ e^- \widetilde{\gamma})^-$  0.10. BR = 0.05 gives 33.5 GeV limit. ³⁹ BARTEL 84C search for  $e^+ e^- \to \widetilde{Z} + \widetilde{\gamma}$  with  $\widetilde{Z} \to \widetilde{\gamma} + e^+ e^-$ ,  $\mu^+ \mu^-$ ,  $q\overline{q}$ , etc. They see no acoplanar events with missing- $p_{\widetilde{T}}$  due to two  $\widetilde{\gamma}$ 's. Above example limit is for  $m_{\widetilde{e}}$ = 40 GeV and for light stable  $\widetilde{\gamma}$  with B( $\widetilde{Z} 
  ightarrow e^+e^-\widetilde{\gamma}$ ) = 0.1.
- ⁴⁰ ELLIS 84 find if lightest neutralino is stable, then  $m_{\widetilde{\chi}0}$  not 100 eV 2 GeV (for  $m_{\widetilde{q}}=$ 40 GeV). The upper limit depends on  $m_{\widetilde{q}}$  (similar to the  $\widetilde{\gamma}$  limit) and on nature of  $\widetilde{\chi}^0$ . For pure higgsino the higher limit is 5 GeV.

#### $\tilde{\chi}_{1}^{\pm}$ , $\tilde{\chi}_{2}^{\pm}$ (Charginos) MASS LIMITS

Charginos  $(\widetilde{\chi}^{\pm}$ 's) are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). Mass limits are relatively model dependent, so assumptions concerning branching ratios need to be specified. When specific assumptions are made, e.g. the chargino is a pure w-ino  $(\widetilde{W})$  or pure charged higgsino  $(\widetilde{H}^\pm)$ , the charginos will be labelled as such.

- ⁴¹ ADRIANI 93M limit from  $\Delta\Gamma(Z)$ < 35.1 MeV. For pure wino, the limit is 45.5 GeV.
- ⁴² DECAMP 92 limit is for a general  $\tilde{\chi}^{\pm}$  (all contents).
- 43 HIDAKA 91 limit obtained from LEP and preliminary CDF limits on the gluino mass (as analyzed in BAER 91).
- ⁴⁴ ABREU 90G limit is for a general  $\widetilde{\chi}^{\pm}$ . They assume charginos have a three-body decay
- 45 AKRAWY 90D assume charginos have three-body decay such as  $\ell^+ \, \nu \, \widetilde{\gamma}$  (i.e.  $m_{\widetilde{
  u}} > m_{\widetilde{\chi}+}$ ).

A two-body decay,  $\tilde{\chi}^+ \to \ell \tilde{\nu}$  would have been seen by their search for acoplanar leptons. The result is independent of the hadronic branching ratio. They search for acoplanar electromagnetic clusters and quark jets.

- electromagnetic clusters and quark jets. 46 ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on  $\sigma(\widetilde{\chi}_1^{\pm}\widetilde{\chi}_2^0) \times B(\widetilde{\chi}_1^{\pm} \to \ell\nu_{\ell}\widetilde{\chi}_1^0) \times B(\widetilde{\chi}_2^0 \to \ell^{\pm}\ell^{-}\widetilde{\chi}_1^0)$  as a function of  $m_{\widetilde{\chi}_1^0}$ . Limits range from 3.1 pb  $(m_{\widetilde{\chi}_1^0} = 45~{\rm GeV})$  to 0.6 pb  $(m_{\widetilde{\chi}_1^0} = 100~{\rm GeV})$ . See Fig. 3 for some explicit mass limits as a function of parameters. 47 DATTA 92 avolude some regions in chargino-gluino mass plane from LEP experiments.
- $^{
  m 47\,DATTA}$  92 exclude some regions in chargino-gluino mass plane from LEP experiments.
- **B DREES 91 limit obtained from LEP results within minimal supersymmetry with gauginomass unification condition. They make use of DECAMP 90c analysis plus additional constraint from total Z width. The bound can only be evaded if the chargino mixes with other charged singlets or with gauginos of a right-handed gauge group.

  49 AKESSON 908 assume  $\widetilde{W} \to e\widetilde{\nu}$  with B > 20% and  $m_{\widetilde{\nu}} = 0$ . The limit disappears if  $m_{\widetilde{\nu}} = 0$ . 30 GeV
- 50  BAER 90 is independent of decay modes. Limit from analysis of supersymmetric parameter space restrictions implied by  $\Delta\Gamma(Z)<120$  MeV. These result from decays of Z to all combinations of  $\widetilde{\chi}_i^\pm$  and  $\widetilde{\chi}_j^0$  . Minimal supersymmetry with  $an\!eta>1$  is assumed.
- 51 BARKLOW 90 assume 100%  $\widetilde{W} \to W^* \widetilde{\chi}_1^0$ . Valid up to  $m_{\widetilde{\chi}_1^0} \lesssim [m_{\widetilde{W}} 5 \text{ GeV}]$ . 52 BARKLOW 90 assume 100%  $\widetilde{H} \to H^* \widetilde{\chi}_1^0$ . Valid up to  $m_{\widetilde{\chi}_1^0} \lesssim [m_{\widetilde{H}} 8 \text{ GeV}]$ .
- 53  DECAMP 90C assume charginos have three-body decay such as  $\ell^+ \nu \widetilde{\gamma}$  (i.e.  $m_{\widetilde{\nu}} > m_{\widetilde{\chi}^+}$ ), and branching ratio to each lepton is 11%. They search for acoplanar dimuons, dielectrons, and  $\mu \, e$  events. Limit valid for  $m_{\widetilde{\gamma}} \, < \,$  28 GeV.
- ⁵⁴ ADACHI 89 assume only single photon annihilation in the production. The limit applies for arbitrary decay branching ratios with  $B(\widetilde{X} \to e \nu \widetilde{\gamma}) + B(\widetilde{X} \to \mu \nu \widetilde{\gamma}) + B(\widetilde{X} \to \tau \nu \widetilde{\gamma}) + B(\widetilde{X} \to q \overline{q} \widetilde{\gamma}) = 1$  (lepton universality is *not* assumed). The limit is for  $m_{\widetilde{\gamma}} =$ 0 but a very similar limit is obtained for  $m_{\widetilde{\gamma}}=$  10 GeV. For B $(\widetilde{\chi}\to~q~\overline{q}\,\widetilde{\gamma})=$  1, the limit
- increases to 27.8 GeV. 55 ADEVA 89B assume for  $\ell\nu\tilde{\gamma}$  ( $\ell\tilde{\nu}$ ) mode that B(e) = B( $\mu$ ) = B( $\tau$ ) = 11% (33%) and search for acoplanar dimuons, dielectrons, and  $\mu e$  events. Also assume  $m_{\tilde{\gamma}} <$  20 GeV and for  $\ell \widetilde{\nu}$  mode that  $m_{\widetilde{\nu}}=$  10 GeV.
- ⁵⁶ ANSARI 87D looks for high  $ho_{\mathcal{T}}$   $e^+e^-$  pair with large missing  $ho_{\mathcal{T}}$  at the CERN  $ho_{\mathcal{D}}$ collider at  $E_{\rm cm}=$  546–630 GeV. The limit is valid when  $m_{\widetilde{\nu}}\lesssim$  20 GeV,  ${\rm B}(\widetilde{W}\to e\widetilde{\nu}_e)$
- collider at  $E_{CM} = 546-530$  GeV. The limit is valid when  $m_{\widetilde{\nu}} \gtrsim 20$  GeV, B( $W \rightarrow e V_e$ ) = 1/3, and B( $Z \rightarrow \widetilde{W}^+\widetilde{W}^-$ ) is calculated by assuming pure gaugino eigenstate. See their Fig. 3(b) for excluded region in the  $m_{\widetilde{W}} m_{\widetilde{\nu}}$  plane.

  57 BAER 878 argue that the charged heavy lepton mass limit of 41 GeV obtained by UA1 collaboration (ALBAJAR 878) corresponds to the mass limit of 40 GeV under the assumptions that the LSP (photino) has a mass smaller than 8 GeV and that the gaugino-bird of the properties of the contraction of the properties of the contraction of the contracti higgsino mixing is parametrized by the three minimal supergravity model parameters. In grand unified theories  $m_{\widetilde{\gamma}} < 8$  implies  $m_{\widetilde{g}} < 50$  GeV. For larger gluino masses, this limit can be evaded as discussed in BAER 88.

#### $\tilde{\nu}$ (Sneutrino) MASS LIMIT

The limit depends on the number,  $N(\widetilde{
u})$ , of sneutrinos assumed to be degenerate in mass. Only  $\tilde{\nu}_L$  (not  $\tilde{\nu}_R$ ) exist. It is possible that  $\tilde{\nu}$  could be the lightest supersymmetric particle (LSP).

- ⁵⁸ ADRIANI 93M limit from  $\Delta\Gamma(Z)$ (invisible)< 16.2 MeV.
- 59  DECAMP 92 limit is from  $\Gamma(\text{invisible})/\Gamma(\ell\ell)=5.91\pm0.15$  (  $\textit{N}_{\nu}=2.97\pm0.07$  ).
- $^{60}\,\mathrm{ABREU}$  91F limit (>32 GeV) is independent of sneutrino decay mode
- 61 ALEXANDER 91F limit is for one species of  $\widetilde{\nu}$  and is derived from  $\Gamma(\text{invisible, new})/\Gamma(\ell\ell)$
- 62 BUSKULIC 95E looked for  $Z \to \widetilde{\nu}\widetilde{\nu}$ , where  $\widetilde{\nu} \to \nu \chi_1^0$  and  $\chi_1^0$  decays via R-parity violating interactions into two leptons and a neutrino.
- following interactions into two reprints and a neutrino. Since the first section of the firs
- ⁶⁴ FALK 94 puts an upper bound on  $m_{\widetilde{
  u}}$  when  $\widetilde{
  u}$  is LSP by requiring its relic density does
- not overclose the Universe. 65 DREES 91 limits from  $\Delta\Gamma(Z)$  (nonhadronic) < 38.3 MeV. Independent of decay modes. Minimal supersymmetry assumed.
- Minimal supersymmetry assumed. 66 SATO 91 search for high-energy neutrinos from the sun produced by annihilation of sneutrinos in the sun. Sneutrinos are assumed to be stable and to constitute dark matter in our galaxy. SATO 91 follow the analysis of NG 87, OLIVE 88, and GAISSER 86. 67 ADEVA 901 limit is from  $\Delta N_{\nu} < 0.19$ . 68 BAER 90 limit from  $\Delta \Gamma(Z)$  (nonhadronic) < 53 MeV. Independent of decay modes. Mininal supersymmetry assumed. The 95%CL bound is 35.6 GeV.

#### e (Selectron) MASS LIMIT

- ⁶⁹ ADRIANI 93M limit is for  $m_{\widetilde{e}_L}\gg m_{\widetilde{e}_R}$  using acolinear di-lepton events.
- ⁷⁰ DECAMP 92 limit is for  $m_{\widetilde{e}_L}^2 \gg m_{\widetilde{e}_R}^7$ ; for equal masses the limit would improve. They looked for acoplanar electrons.
- 71  BUSKULIC 95E looked for  $Z\to \widetilde{e}_R^+\,\widetilde{e}_R^-$  where  $\widetilde{e}_R\to e\chi_1^0$  and  $\chi_1^0$  decays via *R*-parity violating interactions into two leptons and a neutrino.
- 72 HOSODA 94 combines the results of HOSODA 94, HEARTY 89, BEHREND 88B, and FORD 86. 73 AKESSON 90B assume  $m_{\widetilde{\gamma}}=0$ . Very similar limits hold for  $m_{\widetilde{\gamma}}\lesssim 20$  GeV.
- 74  AKRAWY 90D look for acoplanar electrons. For  $m_{\widetilde{e}_L} \ \gg \ m_{\widetilde{e}_R}$ , limit is 41.5 GeV, for  $m_{\widetilde{\gamma}}$  < 30 GeV.
- 75  BAER 90 limit from  $\Delta\Gamma(Z)$  (nonhadronic) <53 MeV. Independent of decay modes. __ Mininal supersymmetry and  $\tan\beta~>1$  assumed.
- ⁷⁶ DECAMP 90C look for acoplanar electrons. For  $m_{\widetilde{e}_L} \gg m_{\widetilde{e}_R}$  limit is 42 GeV, for
- 77 ZHUKOVSKII 90 set limit by saying the luminosity of a magnetized neutron star due to massless photino emission by electrons be small compared with its neutrino luminosity.

- 78  ADACHI 89 assume only photon and photino exchange and  $m_{\widetilde{e}_l}=m_{\widetilde{e}_R}.$  The limit for the nondegenerate case is 26 GeV.
- 79 ADEVA 89B look for acoplanar electrons.
- 80 ALBAJAR 89 limit applies for  $\tilde{e}_L$  when  $m_{\tilde{e}_L}=m_{\widetilde{\nu}_L}$  and  $m_{\widetilde{\gamma}}=0$ . See their Fig. 55 for the 90% CL excluded region in the  $m_{\tilde{e}_L}-m_{\widetilde{\nu}_L}$  plane. For  $m_{\widetilde{\nu}}=m_{\widetilde{\gamma}}=0$ , limit is 50  $^{\mbox{GeV}.}$  81 ALBAJAR 89 assume  $m_{\widetilde{\gamma}}=$  0.
- $^{82}\,\mathrm{HEARTY}$  89 assume  $m_{\widetilde{\gamma}^{'}}=$  0. The limit is very sensitive to  $m_{\widetilde{\gamma}^{'}};$  no limit can be placed for  $m_{\widetilde{\gamma}}\gtrsim$  13 GeV.
- ⁸³ The limit is reduced to 43 GeV if only one  $\tilde{e}$  state is produced ( $\tilde{e}_L$  or  $\tilde{e}_R$  very heavy).
- 84  Results of HEARTY 89, BEHREND 888, ADEVA 87, and FORD 86 are combined. The limit is reduced to 53 GeV if only one  $\tilde{e}$  state is exchanged ( $\tilde{e}_L$  or  $\tilde{e}_R$  very heavy).
- 85 BEHREND 888 limits assume pure photino eigenstate and  $m_{\widetilde{e}_L} = m_{\widetilde{e}_R}$ .
- ⁸⁶ The 95% CL limit for BEHREND 88B is 47.5 GeV for  $m_{\widetilde{\gamma}}=\tilde{0}$ . The limit for  $m_{\widetilde{e}_l}\gg$  $m_{\widetilde{e}_R}$  is 40 GeV at 90% CL.
- ⁸⁷ BEHREND 88B combined their data with those from ASP (HEARTY 87), MAC (FORD 86), and MARK-J (H. Wu, Ph. D. Thesis, University of Hamburg, 1986).

- BUSKULIC 95E looked for  $Z \to \widetilde{\tau}_R^+ \widetilde{\tau}_R^-$ , where  $\widetilde{\tau}_R \to \tau \chi_1^0$  and  $\chi_1^0$  decays via R-parity violating interactions into two leptons and a neutrino. 100 BAER 90 limit from  $\Delta\Gamma(Z)$  (nonhadronic) < 53 MeV. Independent of decay modes. Mininal supersymmetry and  $\tan\beta > 1$  assumed. 101 DECAMP 90c look for acoplanar charged particle pairs. Limit is for  $m_{\widetilde{\tau}_L} = m_{\widetilde{\tau}_R}^-$ . For  $m_{\widetilde{\gamma}} \le 24$  GeV, the limit is 37 GeV. For  $m_{\widetilde{\tau}_L} \gg m_{\widetilde{\tau}_R}^-$  and  $m_{\widetilde{\gamma}} < 15$  GeV, the limit is 33 GeV.

 $^{102} {\rm ADACHI}$  89 assume only photon exchange, which gives a conservative limit.  $m_{\widetilde{\tau}_l} =$  $m_{\widetilde{ au}_R}$  assumed.

#### Stable $\widetilde{\ell}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum  $e^+e^-$  annihilation are also independent of flavor for smuons and staus. However, selectron limits from continuum  $e^+e^-$  annihilation depend on flavor because there is an additional contribution from neutralino exchange that in general yields stronger limits. All limits assume  $m_{\widetilde{\ell}_{i}}$  $m_{\widetilde{\ell}_B}$  unless otherwise stated.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>40	95	ABREU	90G	DLPH

 103  SAKAI 90 limit improves to 30.1 GeV for  $\widetilde{e}$  if  $m_{\widetilde{\gamma}} \approx m_{\widetilde{e}}$ .

 104  ADACHI 89 assume only photon (and photino for  $\widetilde{e}$ ) exchange. The limit for  $\widetilde{e}$  improves to 26 GeV for  $m_{\widetilde{\gamma}} \approx m_{\widetilde{e}}$ .

#### q (Squark) MASS LIMIT

For  $m_q^2 >$  60–70 GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included. The limits from  ${\it Z}$ decay do not assume GUT relations and are more model independent.

105 ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing  $E_{\mathcal{T}}$ . The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limit is derived for

#### Supersymmetric Particle Searches

- fixed  $\tan\beta=4.0$ ,  $\mu=-400$  GeV, and  $m_{H^+}=500$  GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario.
- scenario. Scenario. 106 ABACHI 95C assume five degenerate squark flavors with  $m_{\widetilde{q}_L}=m_{\widetilde{q}_R}$ . Sleptons are assumed to be heavier than squarks. The limits are derived for fixed  $\tan\beta=2.0~\mu=-250~{\rm GeV}$ , and  $m_{H^+}{=}500~{\rm GeV}$ , and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space. No limit is given for  $m_{\rm gluino}$  >547 GeV.
- 107  ABE 95T looked for a cascade decay of five degenerate squarks into  $\widetilde{\chi}_2^0$  which further decays into  $\widetilde{\chi}_1^0$  and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For  $\mu=-40$  GeV,  $\tan\beta=1.5$ , and heavy gluinos, the range  $50{<}m_{\widetilde{q}}$  (GeV)<110 is excluded at 90% CL. See the paper for details.
- 108 BUSKULIC 95E looked for  $Z \to \widetilde{q} \overline{\widetilde{q}}$ , where  $\widetilde{q} \to q \chi_1^0$  and  $\chi_1^0$  decays via R-parity violating interactions into two leptons and a neutrino.
- 109  AHMED 94B looked for squarks as s-channel resonance in ep collision via R-parity violating coupling in the superpotential  $W=\lambda L_1\,Q_1\,d_1$ . The degeneracy of all squarks  $Q_1$  and  $d_1$  is assumed. The squarks decay dominantly via the same R-violating coupling into eq or  $\nu q$  if  $\lambda \gtrsim 0.2$ . For smaller  $\lambda$ , decay into photino is assumed which subsequently decays into  $eq\,q_1$ , and the bound depends on  $m_{\widetilde{\gamma}}$ . See paper for excluded region on  $(m_{\widetilde{q}},\lambda)$  plane.
- 110  ADRIANI 93M limit from  $\Delta\Gamma(Z)<$  35.1 MeV and assumes  $m_{\widetilde{q}_L}\gg m_{\widetilde{q}_R}$
- 111 ABE 92L assume five degenerate squark flavors and  $m_{\widetilde{q}_L} = m_{\widetilde{q}_R}^2$ . ABE 92L includes the effect of cascade decay, for a particular choice of parameters,  $\mu = -250$  GeV,  $\tan\beta = 2$ . Results are weakly sensitive to these parameters over much of parameter space. No limit for  $m_{\widetilde{q}} \leq 50$  GeV (but other experiments rule out that region). Limits are 10–20 GeV higher if  $\mathbb{B}(\widetilde{q} \to q \widetilde{\gamma}) = 1$ . Limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for  $|\mu|$  not small,  $m_{\widetilde{\chi}\widetilde{q}} \approx m_{\widetilde{g}}/6$ . This last
  - relation implies that as  $m_{\widetilde{g}}$  increases, the mass of  $\widetilde{\chi}_{0}^{0}$  will eventually exceed  $m_{\widetilde{q}}$  so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for  $m_{\widetilde{g}} > 410$  GeV.  $m_{H^{+}} = 500$  GeV.
- 112 ABE 92L bounds are based on similar assumptions as ABACHI 95C. No limits for  $\|m_{gluino}\>\!>\!\!410$  GeV.
- 113 ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R-parity violating models. The 100% decay  $\tilde{q} \to q \tilde{\chi}$  where  $\tilde{\chi}$  is the LSP, and the LSP decays either into  $\ell q \bar{d}$  or  $\ell \ell \bar{e}$  is assumed.
- 114 NOJIRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.
- 115  ABREU 90r assume six degenerate squarks and  $m_{\widetilde{q}_L}=m_{\widetilde{q}_R}.~m_{\widetilde{q}}~<$  41 GeV is excluded at 95% CL for  $m_{\rm LSP}~< m_{\widetilde{q}}$  –2 GeV.
- $^{116}\,\mathrm{ABREU}$  90F exclude  $m_{\widetilde{d}}$  < 38 GeV at 95% for  $m_{\mathrm{LSP}}$  <  $m_{\widetilde{d}}$  –2 GeV.
- $^{117}\,\mathrm{ABREU}$  90F exclude  $m_{\widetilde{u}}$   $\,<$  36 GeV at 95% for  $m_{\mathrm{LSP}}$   $\,<$   $m_{\widetilde{u}}$  –2 GeV.
- 118 ALITTI 90 searched for events having  $\geq 2$  jets with  $E_T^1 > 25$  GeV,  $E_T^2 > 15$  GeV,  $|\eta| < 0.85$ , and  $\Delta \phi < 160^\circ$ , with a missing momentum > 40 GeV and no electrons. They assume  $\tilde{q} \to q \tilde{\gamma}$  (if  $m_{\tilde{q}} < m_{\tilde{g}}$ ) or  $\tilde{q} \to q \tilde{g}$  (if  $m_{\tilde{q}} > m_{\tilde{g}}$ ) decay and  $m_{\tilde{\gamma}} \lesssim 20$  GeV. Five degenerate squark flavors and  $m_{\tilde{q}_L} = m_{\tilde{q}_R}$  are assumed. Masses below 50 GeV are not excluded by the analysis.
- 119 BAER 90 limit from  $\Delta \Gamma(Z) <$  120 MeV, assuming  $m_{\widetilde{d}_L} = m_{\widetilde{e}_L} = m_{\widetilde{e}_L}$  Independent of decay modes. Minimal supergravity assumed.
- 120 BARKLOW 90 assume 100%  $\tilde{q} \rightarrow q \tilde{\gamma}$ .
- 121 BARKLOW 90 assume five degenerate squarks (left- and right-handed). Valid up to  $m_{\widetilde{\chi}^0_1} \lesssim [m_{\widetilde{q}}^{-4}~{\rm GeV}].$
- 122 BARKLOW 90 result valid up to  $m_{\widetilde{\chi}_1^0} \lesssim [m_{\widetilde{d}} 5 \text{ GeV}].$
- ¹²³BARKLOW 90 result valid up to  $m_{\widetilde{\chi}_1^0} \lesssim [m_{\widetilde{u}}$  -6 GeV].
- 124  ADACHI 89 assume only photon exchange, which gives a a conservative limit. The limit is only for one flavor of charge  $2/3~\widetilde{q}.~m_{\widetilde{q}_L}=m_{\widetilde{q}_R}$  and  $m_{\widetilde{\gamma}}=0$  assumed. The limit decreases to 26.1 GeV for  $m_{\widetilde{\gamma}}=15$  GeV. The limit for nondegenerate case is 24.4 GeV.
- 125  NATH 88 uses Kamioka limit of  $\tau(p\to \overline{\nu}K^+)>7\times 10^{31}$  yrs to constrain squark mass  $m_{\widetilde{q}}>1000$  GeV by assuming that the proton decay proceeds via an exchange of a color-triplet Higgsino of mass  $<10^{16}$  GeV in the supersymmetric SU(5) GUT. The limit applies for  $m_{\widetilde{\gamma}}\equiv (8/3)\sin^2\!\theta_W\widetilde{m}_2>10$  GeV  $(\widetilde{m}_2$  is the SU(2) gaugino mass) and for a very conservative value of the three-quark proton wave function, barring cancellation between second and third generations. Lower squark mass is allowed if  $m_{\widetilde{\gamma}}$  as defined above in graphic.
- above is smaller.

  126 The limits of ALBAJAR 87D are from  $p\overline{p} \to \widetilde{q}\,\overline{\widetilde{q}}\,X$  ( $\widetilde{q} \to q\widetilde{\gamma}$ ) and assume 5 flavors of degenerate mass squarks each with  $m_{\widetilde{q}_L} = m_{\widetilde{q}_R}$ . They also assume  $m_{\widetilde{g}} > m_{\widetilde{q}}$ . These limits apply for  $m_{\widetilde{\gamma}} \lesssim 20$  GeV.

#### $\tilde{t}$ (Stop) MASS LIMIT

Limit depends on decay mode. In  $e^+e^-$  collisions they also depend on the mixing angle of the mass eigenstate  $\tilde{t}_1=\tilde{t}_L\cos\theta_t+\tilde{t}_R\sin\theta_t$ . Coupling to Z vanishes when  $\theta_t=0.98$ . In the Listings below, we use  $\Delta m\equiv m_{\tilde{t}_1}-m_{\widetilde{\chi}_1^0}$ . See also bound in " $\tilde{q}$  (Squark) MASS LIMIT."

VALUE (GeV)	CL%_	DOCUMENT ID	TECN	COMMENT

none 11–41 95 129 BUSKULIC 95E ALEP  $\theta_t$ =0.98,  $\widetilde{t} \rightarrow c \nu \ell \overline{\ell}'$  130 BAER 91B RVUE  $\widetilde{t}$  131 DREES 90 RVUE  $\widetilde{t}$ 

- ¹²⁷ABACHI 96B searches for final states with 2 jets and missing  $E_{\mathcal{T}}$ . Limits on  $m_{\widetilde{\ell}}$  are given as a function of  $m_{\widetilde{\chi}_1^0}$ . See Fig. 4 for details.
- 128 SHIRAI 94 bound assumes the cross section without the s-channel Z-exchange and the QCD correction, underestimating the cross section up to 20% and 30%, respectively. They assume  $m_C$ =1.5 GeV.
- ¹²⁹ BUSKULIC 95E looked for  $Z \to \tilde{t}\tilde{t}$ , where  $\tilde{t} \to c \chi_1^0$  and  $\chi_1^0$  decays via *R*-parity violating interactions into two leptons and a neutrino.
- 130 BAER 91B argue that a top squark as light as 45 GeV may have escaped detection at the CDF detector at the Tevatron Collider (45 GeV is the limit from LEP experiments).
- 131 DREES 90 argue that bounds from Z decay are not valid for  $\tilde{t}$  for a certain range of  $\tilde{t}_L$ - $\tilde{t}_R$  mixing angle.

#### g (Gluino) MASS LIMIT

For  $m_{\widetilde{g}} > 60$ –70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

There is an ongoing controversy (reflected in these Listings) about whether very light  $\tilde{g}$ 's (1  $\lesssim m_{\widetilde{g}} \lesssim$  4 GeV) are ruled out. These papers sometimes make different assumptions and use different calculational techniques.

- 132  ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing  $E_T$ . The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limits are derived for fixed  $\tan \beta = 4.0$ ,  $\mu = -400$  GeV, and  $m_{H^+} = 500$  GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the values of the three fixed parameters for a large fraction of parameter space. See Fig. 2 for the limits corresponding to different parameter choices. parameter choices.
- 133 ABACHI 95C assume five degenerate squark flavors with with  $m_{\widetilde{q}_L}=m_{\widetilde{q}_R}$ . Sleptons are assumed to be heavier than squarks. The limits are derived for fixed  $\tan\beta=2.0~\mu=$ are assumed to be heavier than squarks. The limits are derived for fixed  $\tan\beta = 2.0~\mu = -250~{\rm GeV}$ , and  $m_{H^+} = 500~{\rm GeV}$ , and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.  $134~{\rm ABE~95T~looked~for~a~cascade~decay~of~gluino~into~\chi_0^2~which further decays~into~\chi_0^2~and a large fraction of~according to the control of the co$

photon. No signal is observed. Limits vary widely depending on the choice of parameters. For  $\mu=-40$  GeV,  $\tan\beta=1.5$ , and heavy squarks, the range  $50< m_{\widetilde{p}}$  (GeV)<140 is excluded at 90% CL. See the paper for details.

135 AKERS 95R looked for Z decay into  $q \bar{q} \tilde{g} \tilde{g}$ , by searching for charged particles with dE/dx

Anema son nounced for z decay into q q g g, by searching for charged particles with dE/dx consistent with  $\tilde{g}$  fragmentation into a state  $(\tilde{g} q \tilde{q})^{\pm}$  with lifetime  $\tau > 10^{-7}$  sec. The fragmentation probability into a charged state is assumed to be 25%. 136 CLAVELLI 95 updates the analysis of CLAVELLI 93, based on a comparison of the hadronic widths of charmonium and bottomonium 5-wave states. The analysis includes a parametrization of relativisitic corrections. Claims that the presence of a light gluino improves agreement with the data by slowing down the running of  $\alpha_s$ .

137 HEBBEKER 93 combined jet analyses at various  $e^+e^-$  colliders. The 4-jet analyses at TRISTAN/LEP and the measured  $\alpha_{\rm S}$  at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks  $N\!=\!6.3\pm1.1$  is obtained, which is compared to that with a light gluino,  $N\!=\!8$ .

138 LOPEZ 93C uses combined restraint from the radiative symmetry breaking scenario within the minimal supergravity model, and the LEP bounds on the  $(M_2,\mu)$  plane. Claims that

the light gluino window is strongly disfavored.

139 ABE 92L bounds are based on similar assumptions as ABACHI 95c. Not sensitive to  $m_{\rm gluino}$  <40 GeV (but other experiments rule out that region).

140 CLAVELLI 92 claims that a light gluino mass around 4 GeV should exist to explain the discrepancy between  $\alpha_{\rm S}$  at LEP and at quarkonia ( $\gamma$ ), since a light gluino slows the running of the QCD coupling.

141 ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in *R*-parity violating models. The 100% decay  $\tilde{g} \to q \overline{q} \tilde{\chi}$  where  $\tilde{\chi}$  is the LSP, and the LSP decays either into  $\ell q \overline{d}$  or  $\ell \ell \overline{e}$  is assumed.

 142  ANTONIADIS 91 argue that possible light gluinos (< 5 GeV) contradict the observed running of  $\alpha_{\rm S}$  between 5 GeV and  $m_Z$ . The significance is less than 2 s.d.  143  ANTONIADIS 91 interpret the search for missing energy events in 450 GeV/c  $\rho$  N collibrations.

sions, AKESSON 91, in terms of light gluinos.

144 HIDAKA 91 limit obtained from LEP and preliminary CDF results within minimal supersymmetry with gaugino-mass unification condition. HIDAKA 91 limit extracted from

145 NO JIR 19 1 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.

¹⁴⁶ ALITTI 90 searched for events having  $\geq$  2 jets with  $E_T^1$  > 25 GeV,  $E_T^2$  > 15 GeV,  $\left|\eta
ight|~<~0.85$ , and  $\Delta\phi~<160^{\circ}$ , with a missing momentum > 40 GeV and no electrons. They assume  $\widetilde{g} \to q \overline{q} \widetilde{\gamma}$  decay and  $m_{\widetilde{\gamma}} \lesssim$  20 GeV. Masses below 50 GeV are not excluded by the analysis.

 147  NAKAMURA 89 searched for a long-lived (  $au \gtrsim 10^{-7}$  s) charge-( $\pm 2$ ) particle with mass  $\lesssim$  1.6 GeV in proton-Pt interactions at 12 GeV and found that the yield is less than  $10^{-8}$  times that of the pion. This excludes R- $\Delta^{++}$  (a  $\tilde{g}uuu$  state) lighter than 1.6

148 The limits of ALBAJAR 87D are from  $p\overline{p} \to \widetilde{g}\widetilde{g}X$  ( $\widetilde{g} \to q\overline{q}\widetilde{\gamma}$ ) and assume  $m_{\widetilde{q}} >$  $m_{\widetilde{g}}.$  These limits apply for  $m_{\widetilde{\gamma}}\lesssim$  20 GeV and  $au(\widetilde{g})<$   $10^{-10}$  s.

149 The limit of ANSARI 87D assumes  $m_{\widetilde{q}} > m_{\widetilde{g}}$  and  $m_{\widetilde{\gamma}} \approx 0$ .

 $^{150}\,\mathrm{The}$  limits assume  $m_{\widetilde{q}}=$  100 GeV. See their figure 3 for limits vs.  $m_{\widetilde{q}}.$ 

151 The gluino mass is defined by half the bound  $\widetilde{g}\widetilde{g}$  mass. If zero gluino mass gives a  $\widetilde{g}\widetilde{g}$  of mass about 1 GeV as suggested by various glueball mass estimates, then the low-mass bound can be replaced by zero. The high-mass bound is obtained by comparing the data with nonrelativistic potential-model estimates.

with nonrelativistic potential-model estimates. 152 ALBRECHT 86c search for secondary decay vertices from  $\chi_{b1}(1P) \to \tilde{g}\,\tilde{g}\,g$  where  $\tilde{g}$ 's make long-lived hadrons. See their figure 4 for excluded region in the  $m_{\tilde{g}} - m_{\tilde{g}}$  and  $m_{\tilde{g}} - m_{\tilde{g}}$  plane. The lower  $m_{\tilde{g}}$  region below  $\sim 2$  GeV may be sensitive to fragmentation effects. Remark that the  $\tilde{g}$ -hadron mass is expected to be  $\sim 1$  GeV (glueball mass) in the record mass limit the zero  $\widetilde{g}$  mass limit.

 $^{153}\, {\sf BADIER}$  86 looked for secondary decay vertices from long-lived  $\widetilde{\it g}$ -hadrons produced at 300 GeV  $\pi^-$  beam dump. The quoted bound assumes  $\tilde{g}$ -hadron nucleon total cross section of 10 $\mu$ b. See their figure 7 for excluded region in the  $m_{\widetilde{g}}-m_{\widetilde{q}}$  plane for several assumed total cross-section values.

154 BARNETT 86 rule out light gluinos (m=3–5 GeV) by calculating the monojet rate from gluino gluino gluon events (and from gluino gluino events) and by using UA1 data from  $p\bar{p}$  collisions at CERN.

155 VOLOSHIN 86 rules out stable gluino based on the cosmological argument that predicts too much hydrogen consisting of the charged stable hadron  $\tilde{g}$  uud. Quasi-stable ( $\tau >$  $1. \times 10^{-7}$ s) light gluino of  $m_{\widetilde{g}} < 3$  GeV is also ruled out by nonobservation of the stable charged particles,  $\widetilde{g}uud$ , in high energy hadron collisions.

The Cooper-SarkAra 85s is BEBC beam-dump. Gluinos decaying in dump would yield  $\tilde{\gamma}$ 's in the detector giving neutral-current-like interactions. For  $m_{\widetilde{q}} > 330$  GeV, no limit

is set. 157 DAWSON 85 first limit from neutral particle search. Second limit based on FNAL beam

158 FARRAR 85 points out that BALL 84 analysis applies only if the  $\tilde{g}$ 's decay before interacting, i.e.  $m_{\tilde{q}} < 80 m_{\tilde{g}}^{-1.5}$ . FARRAR 85 finds  $m_{\tilde{g}} < 0.5$  not excluded for  $m_{\tilde{q}} = 30$ –1000 GeV and  $m_{\tilde{g}} < 1.0$  not excluded for  $m_{\tilde{q}} = 100$ –500 GeV by BALL 84 experiment.

 159  GOLDMAN 85 use nonobservation of a pseudoscalar  $\widetilde{g} extstyle \widetilde{g}$  bound state in radiative  $\psi$ 

decay.
160 HABER 85 is based on survey of all previous searches sensitive to low mass \( \tilde{g}' \)'s. Limit makes assumptions regarding the lifetime and electric charge of the lightest supersymmetric particle.

161 BALL 84 is FNAL beam dump experiment. Observed no interactions of  $\widetilde{\gamma}$  in the calorimeter, where  $\widetilde{\gamma}$ 's are expected to come from pair-produced  $\widetilde{g}$ 's. Search for long-lived  $\widetilde{\gamma}$  interacting in calorimeter 56m from target. Limit is for  $m_{\widetilde{q}}=40$  GeV and production cross section proportional to A $^{0.72}$ . BALL 84 find no  $\tilde{g}$  allowed below 4.1 GeV at CL = 90%. Their figure 1 shows dependence on  $m_{\tilde{q}}$  and A. See also KANE 82.

 162 BRICK 84 reanalyzed FNAL 147 GeV HBC data for R- $\Delta$ (1232) $^{++}$  with  $au~>10^{-9}$  s and  $p_{\text{lab}} > 2$  GeV. Set CL = 90% upper limits 6.1, 4.4, and 29 microbarns in pp,  $\pi^+p$ , K+p collisions respectively.  $R-\Delta^{4+}$  is defined as being  $\tilde{g}$  and 3 up quarks. If mass = 1.2–1.5 GeV, then limits may be lower than theory predictions.

 163  FARRAR 84 argues that  $m_{\widetilde{g}}$  <100 MeV is not ruled out if the lightest R-hadrons are long-lived. A long lifetime would occur if R-hadrons are lighter than  $\widetilde{\gamma}$ 's or if  $m_{\widetilde{a}} > 100$ 

 164 BERGSMA 83C is reanalysis of CERN-SPS beam-dump data. See their figure 1.

165 CHANOWITZ 83 find in bag-model that charged s-hadron exists which is stable against strong decay if  $m_{\widetilde{g}} < 1$  GeV. This is important since tracks from decay of neutral s-hadron cannot be reconstructed to primary vertex because of missed  $\widetilde{\gamma}$ . Charged s-hadron leaves track from vertex.

166 KANE 82 inferred above  $\widetilde{g}$  mass limit from retroactive analysis of hadronic collision and beam dump experiments. Limits valid if  $\widetilde{g}$  decays inside detector.

#### Unstable $\tilde{\gamma}$ (Photino) MASS LIMIT

Unless stated otherwise, the limits below assume that the  $\tilde{\gamma}$  decays either into  $\gamma \tilde{G}$  (goldstino) or into  $\gamma \tilde{H}^0$  (Higgsino)

Stille) or lift	υγπ-(niggsi	110).

		175 CABIBBO	81 COSM	

 167  BUSKULIC 95E looked for  $e^+e^- \to \tilde{\chi}^0_1 \tilde{\chi}^0_1$ , where  $\tilde{\chi}^0_1$  decays via R-parity violating interaction into one neutrino and two opposite-charge leptons. The bound applies provided that B( $Z \to \tilde{\chi}^0_1 \tilde{\chi}^0_1 > 3 \times 10^{-5} \beta^3$ ,  $\beta$  being the final state  $\tilde{\chi}^0_1$  velocity.

168 BUSKULIC 95E looked for  $e^+e^- o ilde{\gamma} ilde{\gamma} ilde{\gamma}$ , where  $ilde{\gamma}$  decays via R-parity violating interaction into one neutrino and two opposite-charge leptons. They extend the domain in the  $(m_{\widetilde{e}}, m_{\widetilde{\gamma}})$  plane excluded by ACTON 93G to  $m_{\widetilde{e}} >$  220 GeV/ $c^2$  (for  $m_{\widetilde{\gamma}} =$  15 GeV/ $c^2$ ) and to  $m_{\widetilde{\gamma}} > 2~{\rm GeV}/c^2$  (for  $m_{\widetilde{e}} < 220~{\rm GeV}/c^2).$ 

169 ACTON 93G assume *R*-parity violation and decays  $\widetilde{\gamma} \to \tau^\pm \ell^\mp \nu_\ell$  ( $\ell=e$  or  $\mu$ ). They exclude  $m_{\widetilde{\gamma}}=4$ –43 GeV for  $m_{\widetilde{e}_L}<$ 42 GeV, and  $m_{\widetilde{\gamma}}=7$ –30 GeV for  $m_{\widetilde{e}_L}<$ 100 GeV (95% CL). Assumes  $\widetilde{e}_R$  much heavier than  $\widetilde{e}_L$ , and lepton family number violation but  $L_e$ - $L_\mu$  conservation.

 170  ABE 89J exclude  $m_{\widetilde{\gamma}}=$  0.15–25 GeV (95%CL) for d= (100 GeV) 2  and  $m_{\widetilde{e}}=$  40 GeV in the case  $\widetilde{\gamma} \to \gamma \, \widetilde{G}$ , and  $m_{\widetilde{\gamma}}$  up to 23 GeV for  $m_{\widetilde{e}} =$  40 GeV in the case  $\widetilde{\gamma} \to \gamma \, \widetilde{H}^0$ .

171 BEHREND 878 limit is for unstable photinos only. Assumes B( $\widetilde{\gamma} \to \gamma(\widetilde{G} \, \text{or} \, \widetilde{H}^0)$ ) =1,  $m_{\widetilde{G} \text{or}} H^0 \ll m_{\widetilde{\gamma}}$  and pure  $\widetilde{\gamma}$  eigenstate.  $m_{\widetilde{e}_L} = m_{\widetilde{e}_R} < 100 \, \text{GeV}$ .

 172  ADEVA 85 is sensitive to  $\tilde{\gamma}$  decay path <5 cm. With  $m_{\tilde{\alpha}} = 50$  GeV, limit (CL = 90%) is  $m_{\widetilde{\gamma}} >$  20.5 GeV. Assume  $\widetilde{\gamma}$  decays to photon + goldstino and search for acoplanar photons with large missing  $ho_{\mathcal{T}}$ .

173 BALL 84 is FNAL beam dump experiment. Observed no  $\tilde{\gamma}$  decay, where  $\tilde{\gamma}$ 's are expected to come from  $\tilde{g}$ 's produced at the target. Three possible  $\tilde{\gamma}$  lifetimes are considered. Gluino decay to goldstino + gluon is also considered.

## Supersymmetric Particle Searches

174 BEHREND 83 and BARTEL 84B look for  $2\gamma$  events from  $\widetilde{\gamma}$  pair production. With supersymmetric breaking parameter d =  $(100~{\rm GeV})^2$  and  $m_{\widetilde{\varrho}}=40~{\rm GeV}$  the excluded regions at CL = 95% would be  $m_{\widetilde{\gamma}}=100~{\rm MeV}-13~{\rm GeV}$  for BEHREND 83  $m_{\widetilde{\gamma}}=80~{\rm MeV}-18~{\rm GeV}$  for BARTEL 84B. Limit is also applicable if the  $\widetilde{\gamma}$  decays radiatively within the detector. 
175 CABIBBO 81 consider  $\widetilde{\gamma}\to\gamma+$  goldstino. Photino must be either light enough (<30 eV) to satisfy cosmology bound, or heavy enough (>0.3 MeV) to have disappeared at early universe.

# Quark and Lepton Compositeness, Searches for

# SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale  $(\Lambda)$ , these interactions are suppressed by inverse powers of  $\Lambda$ . The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2} \left[ \eta_{LL} \, \overline{\psi}_L \, \gamma_\mu \, \psi_L \, \overline{\psi}_L \, \gamma^\mu \, \psi_L + \eta_{RR} \, \overline{\psi}_R \, \gamma_\mu \, \psi_R \, \overline{\psi}_R \, \gamma^\mu \, \psi_R \right.$$
$$\left. + 2\eta_{LR} \, \overline{\psi}_L \, \gamma_\mu \, \psi_L \, \overline{\psi}_R \, \gamma^\mu \, \psi_R \right] . \tag{1}$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size  $\Lambda$ . We may determine the scale  $\Lambda$  unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting  $g^2/4\pi = g^2(\Lambda)/4\pi = 1$  for the new strong interaction coupling and by setting the largest magnitude of the coefficients  $\eta_{\Omega\beta}$  to be unity. In the following, we denote

$$\begin{split} & \Lambda = \Lambda_{LL}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (\pm 1,\, 0,\, 0) \;, \\ & \Lambda = \Lambda_{RR}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (0,\, \pm 1,\, 0) \;, \\ & \Lambda = \Lambda_{VV}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (\pm 1,\, \pm 1,\, \pm 1) \;, \\ & \Lambda = \Lambda_{AA}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (\pm 1,\, \pm 1,\, \mp 1) \;, \end{split} \label{eq:lambda}$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, e.g., for  $ee \rightarrow ee$ ) and/or by exchange of the binding quanta (whenever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks ( $\ell^*$  and  $q^*$ ). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron  $e^*$  is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for  $g^-2$  suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by  $SU(2)\times U(1)$  quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix} 
u^* \\ \ell^* \end{pmatrix}_L$$
 ,  $[
u_R^*]$  ,  $\ell_R^*$  .

 $\nu_R^*$  is necessary unless  $\nu^*$  has a Majorana mass.

2. Mirror type

$$[
u_L^*] \;, \qquad \ell_L^* \;, \qquad \left(egin{array}{c} 
u^* \ \ell^* \end{array}
ight)_R \;.$$

3. Homodoublet type

$$\begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_L \;, \qquad \begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_R \;.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in "Standard Model of Electroweak Interactions"):

	Sequential type	Mirror type	Homodoublet type
$V^{\ell^*} A^{\ell^*}$	$-\frac{1}{2} + 2\sin^2\theta_W$	$-\frac{1}{2} + 2\sin^2\theta_W$	$-1 + 2\sin^2\theta_W$
	$-\frac{1}{2}$	$+\frac{1}{2}$	0
$V^{ u_D^*}$	$+\frac{1}{2}$	$+\frac{1}{2}$	+1
$A^{ u_D^*}$	$+\frac{1}{2}$	$-\frac{\overline{1}}{2}$	0
$V^{ u_M^*}$	0	0	and the same of th
$A^{ u_M^*}$	+1	-1	-

Here  $\nu_D^*$  ( $\nu_M^*$ ) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at  $q^2 \neq 0$ , they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parametrized as follows:

$$\mathcal{L} = \frac{\lambda_{\gamma}^{(f^{*})} e}{2m_{f^{*}}} \overline{f}^{*} \sigma^{\mu\nu} (\eta_{L} \frac{1-\gamma_{5}}{2} + \eta_{R} \frac{1+\gamma_{5}}{2}) f F_{\mu\nu} 
+ \frac{\lambda_{Z}^{(f^{*})} e}{2m_{f^{*}}} \overline{f}^{*} \sigma^{\mu\nu} (\eta_{L} \frac{1-\gamma_{5}}{2} + \eta_{R} \frac{1+\gamma_{5}}{2}) f Z_{\mu\nu} 
+ \frac{\lambda_{W}^{(\ell^{*})} g}{2m_{\ell^{*}}} \overline{\ell}^{*} \sigma^{\mu\nu} \frac{1-\gamma_{5}}{2} \nu W_{\mu\nu} 
+ \frac{\lambda_{W}^{(\nu^{*})} g}{2m_{\nu^{*}}} \overline{\nu}^{*} \sigma^{\mu\nu} (\eta_{L} \frac{1-\gamma_{5}}{2} + \eta_{R} \frac{1+\gamma_{5}}{2}) \ell W_{\mu\nu}^{\dagger} 
+ \text{h.c.},$$
(3)

where  $g=e/\sin\theta_W$ ,  $F_{\mu\nu}=\partial_{\mu}A_{\nu}-\partial_{\nu}A_{\mu}$  is the photon field strength,  $Z_{\mu\nu}=\partial_{\mu}Z_{\nu}-\partial_{\nu}Z_{\mu}$ , etc. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L \eta_R = 0 \ . \tag{4}$$

These couplings can arise from  $SU(2)\times U(1)$ -invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type  $\ell^*$  with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda} \overline{L}^* (g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \frac{1 - \gamma_5}{2} L + \text{h.c.} , \qquad (5)$$

#### **Quark and Lepton Compositeness**

where L denotes the lepton doublet  $(\nu,\ell)$ ,  $\Lambda$  is the compositeness scale, g, g' are SU(2) and U(1) $_Y$  gauge couplings, and  $W^a_{\mu\nu}$  and  $B_{\mu\nu}$  are the field strengths for SU(2) and U(1) $_Y$  gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the  $\ell^*$  and  $\nu^*$  couplings become unrelated, and the couplings receive the extra suppression of  $(250\,{\rm GeV})/\Lambda$  or  $m_{L^*}/\Lambda$ . In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2}\sin^2\theta_W(\lambda_Z \cot\theta_W + \lambda_\gamma) \ . \tag{6}$$

Additional coupling with gluons is possible for excited quarks:

$$\mathcal{L} = \frac{1}{2\Lambda} \overline{Q}^* \sigma^{\mu\nu} \left( g_s f_s \frac{\lambda^a}{2} G^a_{\mu\nu} + g f \frac{\tau^a}{2} W^a_{\mu\nu} + g' f' Y B_{\mu\nu} \right)$$

$$\times \frac{1 - \gamma_5}{2} Q + \text{h.c.} , \qquad (7)$$

where Q denotes a quark doublet,  $g_s$  is the QCD gauge coupling, and  $G_{u\nu}^a$  the gluon field strength.

Some experimental analyses assume the relation  $\eta_L = \eta_R = 1$ , which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor  $\eta_L^2 + \eta_R^2$  and the limits can be reinterpreted as those for chirality conserving cases  $(\eta_L, \eta_R) = (1,0)$  or (0,1) after rescaling  $\lambda$ .

Several different conventions are used by LEP experiments to express the transition magnetic couplings. To facilitate comparison, we reexpress these in terms of  $\lambda_Z$  and  $\lambda_{\gamma}$  using the following relations and taking  $\sin^2 \theta_W = 0.23$ . We assume chiral couplings, i.e., |c| = |d| in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2} \lambda_Z$$
 (1990 papers) (8a)

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*}[\text{or } m_{\nu^*}]} \quad \text{(for } |c| = |d|)$$
 (8b)

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin \theta_W \cos \theta_W}{\sqrt{\frac{1}{4} - \frac{2}{3} \sin^2 \theta_W + \frac{8}{9} \sin^4 \theta_W}} \lambda_Z = 1.11 \lambda_Z \quad (9)$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot \theta_W - \tan \theta_W} \lambda_Z = -1.10 \lambda_Z$$
 (10)

4. L3 (neutrino)

$$f_Z^{L3} = \sqrt{2}\lambda_Z \tag{11}$$

5. OPAL (charged lepton)

$$\frac{f^{\text{OPAL}}}{\Lambda} = -\frac{2}{\cot \theta_W - \tan \theta_W} \frac{\lambda_Z}{m_{\ell^*}} = -1.56 \frac{\lambda_Z}{m_{\ell^*}} \quad (12)$$

6. OPAL (quark)

$$\frac{f^{\text{OPAL}}c}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad (\text{for } |c| = |d|)$$
 (13)

7. DELPHI (charged lepton)

$$\lambda_{\gamma}^{\rm DELPHI} = -\frac{1}{\sqrt{2}} \, \lambda_{\gamma} \tag{14}$$

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons  $(\ell_8)$  and the ordinary lepton  $(\ell)$  may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_{\ell} \left\{ \overline{\ell}_{8}^{\alpha} g_{S} F_{\mu\nu}^{\alpha} \sigma^{\mu\nu} \left( \eta_{L} \ell_{L} + \eta_{R} \ell_{R} \right) + h.c. \right\}$$
 (15)

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies  $\eta_L$ ,  $\eta_R=0$  as before.

 $^{\rm 1}$  This BUSKULIC 93Q value is from ALEPH data plus PEP/PETRA/TRISTAN data reanalyzed by KROHA 92.

² BUSKULIC 93Q uses the following prescription to obtain the limit: when the naive 95%CL limit is better than the statistically expected sensitivity for the limit, the latter is adopted for the limit.

3 KROHA 92 limit is from fit to BERGER 858, BARTEL 86c, DERRICK 868, FERNANDEZ 878, BRAUNSCHWEIG 88, BEHREND 918, and BEHREND 91c. The fit gives  $\eta/\Lambda_{LL}^2 = +0.230 \pm 0.206 \,\, {\rm TeV}^{-2}$ .

⁴BRAUNSCHWEIG 88 assumed  $m_Z = 92$  GeV and  $\sin^2 \theta_W = 0.23$ .

 5  FERNANDEZ 87B assumed  $\sin^{2}\! heta_{W}^{-}=$  0.22.

 6  BARTEL 86C assumed  $m_Z=93$  GeV and  $\sin^2\!\theta_W=0.217$ .

⁷ DERRICK 86 assumed  $m_Z = 93$  GeV and  $g_V^2 = (-1/2 + 2\sin^2\theta_W)^2 = 0.004$ .

⁸BERGER 85B assumed  $m_Z = 93$  GeV and  $\sin^2 \theta_W = 0.217$ .

- 35  ABE 96 finds that the inclusive jet cross section for  $E_{\mathcal{T}}$  >200 GeV is significantly higher than the  $\mathcal{O}(\alpha_3^3)$  perturbative QCD prediction. This could be interpreted as the effect of a contact interaction with  $\Lambda_{LL} \sim 1.6$  TeV. However, ABE 96 state that uncertainty in the parton distribution functions, higher-order QCD corrections, and the detector calibration may possibly account for the effect.
- 36  Limit is from inclusive jet cross-section data in  $p\overline{p}$  collisions at  $E_{\rm Cm}=1.8$  TeV. The limit takes into account uncertainties in choice of structure functions and in choice of
- 37 ABE 93.6 limit is from dijet mass distribution in  $p\overline{p}$  collisions at  $E_{cm}=1.8$  TeV. The limit is the weakest from several choices of structure functions and renormalization scale. 38 ABE 92M limit is from dijet angular distribution for  $m_{dijet} > 550$  GeV in  $p\overline{p}$  collisions at  $E_{\rm cm}$ =1.8 TeV.
- 39 ALITTI 91B limit is from inclusive jet cross section in  $p\bar{p}$  collisions at  $E_{\rm CM}=630$  GeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale
- 40  ABE 89H limit is from dijet angular distribution for  $m_{\mbox{dijet}} >$  200 GeV at the Fermilab Tevatron Collider with  $E_{\mbox{cm}} = 1.8$  TeV. The QCD prediction is quite insensitive to choice of structure functions and choice of process scale.
- 41 ARNISON 86C limit is from the study of inclusive high- $\rho_T$  jet distributions at the CERN  $\bar{p}_P$  collider ( $E_{\rm Cm}=546$  and 630 GeV). The QCD prediction renormalized to the low- $\rho_T$  region gives a good fit to the data.

  42 ARNISON 86D limit is from the study of dijet angular distribution in the range 240 < m(dijet) < 300 GeV at the CERN  $\bar{p}_P$  collider ( $E_{\rm Cm}=630$  GeV). QCD prediction using
- EHLQ structure function (EICHTEN 84) with  $\Lambda_{QCD}$  = 0.2 GeV for the choice of  $\mathit{Q}^2$  =  $\rho_T^2$  gives the best fit to the data.
- 3 APPEL 85 limit is from the study of inclusive high- p  $_{\mathcal{T}}$  jet distributions at the CERN  $^{\bar{p}}p$  collider ( $E_{\rm Cm}=630$  GeV). The QCD prediction renormalized to the low- p  $_{\mathcal{T}}$  region gives a good description of the data.
- ⁴⁴ BAGNAIA 84C limit is from the study of jet  $p_T$  and dijet mass distributions at the CERN  $\overline{p}p$  collider ( $E_{\rm CM}=540$  GeV). The limit suffers from the uncertainties in comparing the data with the QCD prediction.

#### Quark and Lepton Compositeness

#### MASS LIMITS for Excited e (e*)

Most  $e^+e^-$  experiments assume one-photon or Z exchange. The limits from some  $e^+e^-$  experiments which depend on  $\lambda$  have assumed transition couplings which are chirality violating  $(\eta_L=\eta_R)$ . However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value  $\lambda$  by  $\sqrt{2}$ ; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons"

#### Limits for Excited e (e*) from Pair Production

These limits are obtained from  $e^+e^- \rightarrow e^{*+}e^{*-}$  and thus rely only on the (electroweak) charge of e*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the  $e^*$  coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume  $e^* \rightarrow e\gamma$  decay except the limits from  $\Gamma(Z)$ .

For limits prior to 1987, see our 1992 edition (Physical Review D45, 1 June, Part II

#### Limits for Excited e (e*) from Single Production

These limits are from  $e^+e^- \to e^*e$ ,  $W \to e^*\nu$ , or  $ep \to e^*X$  and depend on transition magnetic coupling between e and  $e^*$ . All limits assume  $e^* \to e\gamma$  decay except as noted. Limits from LEP, UA2, and H1 are for chiral coupling, whereas all other limits are for nonchiral coupling,  $\eta_L=\eta_R=1$ . In most papers, the limit is expressed in the form of an excluded region in the  $\lambda-m_{e^*}$  plane. See the original

For limits prior to 1987, see our 1992 edition (Physical Review D45, 1 June, Part II (1992)). VALUE (GeV) CL% DOCUMENT ID TECN COMMENT

- $^{57}\,\text{BUSKULIC}$  93Q obtain  $\Lambda^+>$  121 GeV (95%CL) from ALEPH experiment and  $\Lambda^+>$  135 GeV from combined TRISTAN and ALEPH data. These limits roughly correspond to limits on  $m_{e^*}$ .
- 58 ADRIANI 92B superseded by ACCIARRI 95G.
  59 BARDADIN-OTWINOWSKA 92 limit from flt to the combined data of DECAMP 92,
- ABREU 91E, ADEVA 90K, AKRAWY 91F.  60  SHIMOZAWA 92 fit the data to the limiting form of the cross section with  $m_{e^*}\gg E_{\rm cm}$ and obtain  $m_{\rm ex}$  >168 GeV at 95%CL. Use of the full form would reduce this limit by a few GeV. The statistically unexpected large value is due to fluctuation in the data.
- 61 The ABE 89J limit assumes chiral coupling. This corresponds to  $\lambda_{\gamma}=$  0.7 for nonchiral coupling.

#### Indirect Limits for Excited e (e*)

These limits make use of loop effects involving  $e^{*}$  and are therefore subject to theoretical uncertainty.

- 62  DORENBOSCH 89 obtain the limit  $\lambda_{\gamma}^2 \Lambda_{\rm Cut}^2/m_{e^*}^2 < 2.6$  (95% CL), where  $\Lambda_{\rm Cut}$  is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that  $\Lambda_{\rm cut}=1$  TeV and  $\lambda_{\gamma}=1$ , one obtains  $m_{e^*}>620$  GeV. However, one generally expects  $\lambda_{\gamma}\approx m_{e^*}/\Lambda_{\rm cut}$  in composite models.
- 63  GRIFOLS 86 uses  $v_{\mu}e \rightarrow v_{\mu}e$  and  $\overline{v}_{\mu}e \rightarrow \overline{v}_{\mu}e$  data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.
- define mass limits which depend on the scale of compositions of embeddings of  $e^*$  and  $\mu^*$ . See figures 2 and 3 of the paper.

#### MASS LIMITS for Excited $\mu$ ( $\mu$ *)

#### Limits for Excited $\mu$ ( $\mu$ *) from Pair Production

These limits are obtained from  $e^+e^- \rightarrow \mu^{*+}\mu^{*-}$  and thus rely only on the (electroweak) charge of  $\mu^*$ . Form factor effects are ignored unless noted. For the case of limits from Z decay, the  $\mu^*$  coupling is assumed to be of sequential type. All limits assume  $\mu^* \to \mu \gamma$  decay except for the limits from  $\Gamma(Z)$ .

- 101  ALITTI 93 search for resonances in the two-jet invariant mass. The limit is for  $f_{\mathcal{S}}=f$  $= f' = \Lambda/m_{q^*}. \ u^* \text{ and } d^* \text{ are assumed to be degenerate. If not, the limit for } u^* (d^*)$  is 277 (247) GeV if  $m_{d^*} \gg m_{u^*} (m_{u^*} \gg m_{d^*})$ .
- ¹⁰² Assumes B( $q^* \rightarrow q\gamma$ ) = 0.1.
- the decays  $q^* \to qW$ , qZ, qg,  $q\gamma$ . See their Fig. 15 for the exclusion plot in the  $m_{q^*} \lambda \gamma$  plane.  103  DERRICK 95B search for single  $q^*$  production via  $q^*\,q\,\gamma$  coupling in  $e\,p$  collisions with
- 104 ABE 94 search for resonances in jet- $\gamma$  and jet-W invariant mass in  $\rho \overline{\rho}$  collisions at  $E_{\rm cm}$ = 1.8 TeV. The limit is for  $f_s=f=f'=\Lambda/m_{q^*}$  and  $u^*$  and  $u^*$  are assumed to be degenerate. See their Fig. 4 for the excluded region in  $m_{q^*}$ -f plane.
- ¹⁰⁵ Assumes B( $q^* \rightarrow qg$ ) = 1.
- 106 ABREU 920 give  $\sigma(e^+e^- \to Z \to q^*\overline{q} \text{ or } q\overline{q}^*) \times \text{B}(q^* \to q\gamma) <$ 15 pb (95% CL) for  $m_{q^*} <$ 80 GeV.
- 107  ADRIANI 92F search for Z  $\rightarrow~q\,q^*$  with  $q^*\rightarrow~q\,\gamma$  and give the limit  $\sigma_Z$   $\cdot~$  B(Z  $\rightarrow~$  $q\,q^*)\,\cdot\,{\rm B}(q^*\,\rightarrow\,\,q\gamma)<\!(2\text{--}10)\,{\rm pb}$  (95%CL) for  $m_{\,q^*}^{}=$  (46–82) GeV.
- $^{108}\,\mathrm{ALBAJAR}$  89 give  $\sigma(q^*\to~W+\mathrm{jet})/\sigma(W)<0.019$  (90% CL) for  $m_{q^*}~>$  220 GeV.
- $^{109}\,\mathrm{BEHREND}$  86C has  $E_\mathrm{cm}=$  42.5–46.8 GeV. See their Fig. 3 for excluded region in the  $m_{q^*} - (\lambda_\gamma/m_{q^*})^2$  plane. The limit is for  $\lambda_\gamma = 1$  with  $\eta_L = \eta_R = 1$ .

#### MASS LIMITS for Color Sextet Quarks (q6)

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>84	95	110 ABE 89	CDF	$p\overline{p} \rightarrow q_6\overline{q}_6$

110 ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color sextet quark is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. A limit of 121 GeV is obtained for a color decuplet.

#### MASS LIMITS for Color Octet Charged Leptons ( $\ell_8$ ) $\lambda \equiv m_{\ell_0}/\Lambda$

		116 BARTEL	85K	JADE	jets $e_8: e^+e^- \rightarrow gg; R$

- 111 ABE 890 look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color octet lepton is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. The limit improves to 99 GeV if it always fragments
- not to decay within the detector. The into a unit-charged hadron. 112 ABT 93 search for  $e_8$  production via e-gluon fusion in  $e_9$  collisions with  $e_8 \rightarrow e_9$ . See their Fig. 3 for exclusion plot in the  $m_{e_8}$ -A plane for  $m_{e_8}$  = 35-220 GeV.
- 113 KIM 90 is at  $E_{\rm cm} = 50$ –60.8 GeV. The same assumptions as in BARTEL 87B are used.
- 114 KIM 90 result  $(m_{\rm e_8} \Lambda_{\rm M})^{1/2} > 178.4$  GeV (95%CL,  $\alpha_8 = 0.16$  used) is subject to the same restriction as for BARTEL 85K. 115 BARTEL 87B is at  $E_{\rm cm} = 46.3$ –46.78 GeV. The limits assume  $\ell_8$  pair production cross sections to be eight times larger than those of the corresponding heavy lepton pair production.
- 116 In BARTEL 85K, R can be affected by  $e^+e^- \to gg$  via  $e_q$  exchange. Their limit  $m_{e_8} > 173$  GeV (CL=95%) at  $\lambda = m_{e_8}/M = 1$  ( $\eta_L = \eta_R = 1$ ) is not listed above because the cross section is sensitive to the product  $\eta_L \eta_R$ , which should be absent in ordinary theory with electronic chiral invariance.

#### MASS LIMITS for Color Octet Neutrinos ( $\nu_8$ )

$\lambda \equiv m_{\ell_8}/\Lambda$		•				
VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT	
>110	90	¹¹⁷ BARGER	89	RVUE	ν ₈ : p p →	$\nu_8 \overline{\nu}_8$
• • We do not use the	e follow	ing data for average	s, fit	s, limits,	etc. • • •	0 0
none 3.8-29.8	95	¹¹⁸ KIM	90	AMY	ν ₈ : e+e-	$\rightarrow  acoplanar$
none 9-21.9	95	¹¹⁹ BARTEL	878	JADE	jets ν ₈ : e ⁺ e ⁻ iets	$\rightarrow  \text{acoplanar}$

- 117 BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay  $\nu_{\rm B} \rightarrow \nu_{\rm Z}$  is assumed. 
  118 KIM 90 is at  $E_{\rm Cm} = 50$ –60.8 GeV. The same assumptions as in BARTEL 87B are used. 
  119 BARTEL 87B is at  $E_{\rm Cm} = 46.3$ –46.78 GeV. The limit assumes the  $\nu_{\rm B}$  pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its  ${\rm SU}(2)_L \times {\rm U}(1)_Y$  quantum numbers.

### Other Particle Searches

#### OMITTED FROM SUMMARY TABLE OTHER PARTICLE SEARCHES

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

- 1. Concentration of stable particles in matter
- 2. Galactic WIMP (weakly-interacting massive particle) searches
- 3. Limits on neutral particle production at accelerators
- 4. Limits on jet-jet resonance in hadron collisions
- 5. Limits on charged particles in  $e^+e^-$  collisions
- 6. Limits on charged particles in hadron reactions
- 7. Limits on charged particles in cosmic rays

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including  $W_R, W', Z'$ , leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, etc.

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

#### GALACTIC WIMP SEARCHES Cross-Section Limits for Dark Matter Particles (X⁰) on Nuclei

These limits are for weakly-interacting stable particles which may constitute the invisible mass in the Galaxy with a local mass density of 0.3 GeV/cm³. See each paper for assumptions on the velocity distribution. In the papers the limit is given as a function of the  $x^0$  mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

#### For $m_{\chi^0} = 20 \text{ GeV}$

VERKERK 92 looked for heavy isotopes in sea water and put a bound on concentration of stable charged massive particle in sea water. The above bound can be translated into into a bound on charged dark matter particle (5  $\times$  10⁶ GeV), assuming the local density,  $\rho$ =0.3 GeV/cm³, and the mean velocity  $\langle v \rangle$ =300 km/s.

³ See HEMMICK 90 Fig. 7 for other masses 100–10000  $m_p$ .

 $^{^5}$  Bound valid up to  $m_{\chi^-}~\sim~100$  TeV.

GARCIA 99 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ²⁷Al and ²⁸Si.
 REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

#### Other Particle Searches

- ⁹ GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for
- diurnal and annual modulation.

  10 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ²⁷Al and ²⁸Si.
- 11 BECK 94 uses enriched ⁷⁶Ge (86% purity).
- 12 REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors.

  J.L. Vuilleumier, private communication, March 29, 1996.

#### LIMITS ON NEUTRAL PARTICLE PRODUCTION

#### Heavy Particle Production Cross Section

VALUE (cm ² /N)	CL%_E	VTS	DOCUMENT ID		TECN	COMMENT
• • • We do not us	se the	following	g data for averages	, fits	, limits,	etc. • • •
< 10-36-10-33			¹⁷ GALLAS	95	TOF	m= 0.5-20 GeV
$<(4-0.3)\times10^{-31}$	95		¹⁸ AKESSON	91	CNTR	m = 0-5  GeV
	90		¹⁹ BADIER	86	BDMP	$\tau = (0.05-1.) \times 10^{-8}$ s
$< 2.5 \times 10^{-35}$		0	²⁰ GUSTAFSON	76	CNTR	$\tau > 10^{-7} \text{ s}$

- 17  GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c  $\rho$  N interactions decaying with a lifetime of  $10^{-4}$ – $10^{-8}$  s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section  $10^{-29}$ – $10^{-33}$  cm².
- 18 AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for  $\tau>10^{-7}\,\mathrm{s}$ . For  $\tau>10^{-9}\,\mathrm{s}$ ,  $\sigma<10^{-30}\,\mathrm{cm}^{-2}/\mathrm{nucleon}$  is obtained.
- $\sigma < 10^{-2}$  cm⁻⁷-indepents obtained.

  19 BADIER 86 looked for long-lived particles at 300 GeV  $\pi^-$  beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass >2 GeV. The limit applies for particle modes,  $\mu^+\pi^-$ ,  $\mu^+\mu^-$ ,  $\pi^+\pi^-$ X,  $\pi^+\pi^-\pi^\pm$  etc. See their figure 5 for the contours of limits in the mass- $\tau$  plane for each mode.
- 20  GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy (m>2 GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for m=3 GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

#### Production of New Penetrating Non- $\nu$ Like States in Beam Dump DOCUMENT ID TECN COMMENT

- 54 SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.
   55 MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 838 below may be due to this fake
- 56 SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10¹⁷ eV may indicate production of very heavy parent at top of atmosphere.
- parent at top or atmosphere. 57 BHAT 82 observed 12 events with delay  $> 2.\times 10^{-8}$  s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle. 58 MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light.
- PENNING α applied PEP-Counter for LOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
- angle is assumed.  59  YOCK 81 saw another 3 events with  $Q=\pm 1$  and m about  $4.5m_p$  as well as 2 events with  $m>5.3m_p$ ,  $Q=\pm 0.75\pm 0.05$  and  $m>2.8m_p$ ,  $Q=\pm 0.70\pm 0.05$  and 1 event with  $m=(9.3\pm3.)m_{p}$ ,  $Q=\pm0.89\pm0.06$  as possible heavy candidates.
- 60  YOCK 80 events are with charge exactly or approximately equal to unity.  61  BHAT 78 is at Kolar gold fields. Limit is for  $\tau>10^{-6}$  s.
- 62 YOCK 74 events could be tritons.

#### Superheavy Particle (Quark Matter) Flux in Cosmic Rays

VALUE (cm ⁻² sr ⁻¹ s ⁻¹ ) • • • We do not	CL%	EVTS	DOCUMENT ID	s. fit	TECN s. limits.	COMMENT etc. • • •
$< 1.8 \times 10^{-12}$	90		⁶³ ASTONE	93	CNTR	$m > 1.5 \times 10^{-13} \text{gram}$
$< 1.1 \times 10^{-14}$	90		64 AHLEN	92	MCRO	$10^{-10} < m < 0.1 \text{ gram}$
$< 3.2 \times 10^{-11}$	90	0	⁶⁵ NAKAMURA			$m > 1.5 \times 10^{-13}$ gram
$< 3.5 \times 10^{-11}$	90	0	⁶⁶ ULLMAN	81	CNTR	Planck-mass 10 ¹⁹ GeV
$< 7. \times 10^{-11}$	90	0	66 ULLMAN	81	CNTR	$m < 10^{16} \text{ GeV}$

- 63  ASTONE 93 searched for quark matter ("nuclearites") in the velocity/c range =  $10^{-3}$ -1. Their Table 1 gives a compilation of searches for nuclearites.
- ⁶⁴ AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity/ $c < 2.5 \times 10^{-3}$ . See their Fig. 3 for other velocity/c and heavier mass range.
- 65  NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity/c of  $10^{-4}$ – $10^{-3}$ .
- 66  ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.

#### Highly Ionizing Particle Flux

Consultants	Damage, biological, from radiation
Conversion probability for photons to $e^+e^-$	DAPNE (Frascati) collider parameters
Correlation coefficient, definition	Dark matter
Cosmic background radiation (CBR)	Dark matter limits:
Cosmic background radiation (CBR) temperature 66	Astrophysical limits on neutrino mass 289
Cosmic background radiation, deviations from isotropy 119	Invisible axion mass limits
Cosmic ray background in counters	Neutralinos mass limits
Cosmic ray air showers	Sneutrino mass limits

Data, averaging and fitting procedures	Earth equatorial radius
Data, selection and treatment	Education
Databases, availability online	Efficiency of statistical estimator, definition
Databases, high-energy physics	Electrical resistivity of elements, table
Databases, particle physics	Electric charge $(Q)$ conservation
Day, sidereal	Electromagnetic calorimeters
dE/dx	Electromagnetic relations
Decay amplitudes (for hyperon decays)	Electromagnetic shower detectors, energy resolution 145
(see p. 286 in our 1982 edition, Phys. Lett. <b>111B</b> )	Electromagnetic showers, lateral distribution
Decay constants of charged pseudoscalar mesons, note on 319	Electromagnetic showers, longitudinal distribution
Decays, kinematics and phase space for	Electron
Deep-inelastic scattering	Electron charge
Definitions for abbreviations used in Particle Listings 200	Electron critical energy
$\delta$ , CKM angle for $CP$ violation	Electron cyclotron frequency/field
$\delta$ -rays	Electron mass
$\delta(980) \ [now \ called \ a_0(980)] \ \ldots \ \ldots \ \ldots \ \ 26, 340$	Electron radius, classical
$\delta_4(2040)$ [now called $a_4(2040)$ ]	Electron volt
$\delta_6(2450) \ [now \ called \ a_6(2450)] \ . \ . \ . \ . \ . \ . \ . \ . \ . \ $	Electronic structure of the elements
$\Delta$ resonances (see also N and $\Delta$ resonances) 50, 600	Electroproduction structure functions, relations for
$\Delta B = 1$ , weak neutral currents, tests for	Electroweak analyses of new physics
$\Delta B = 2$ , tests for	Electroweak interactions, Standard Model of 85
$\Delta C = 1$ , weak neutral currents, tests for	Elements, electronic structure of
$\Delta C = 2$ , tests for	Elements, periodic table of
$\Delta I = 1/2$ rule for hyperon decays, test of	Energy and momentum (c.m.) vs. beam momentum 175
(see p. 286 in our 1982 edition, Phys. Lett. 111B)	Energy loss (fractional) for electrons and positrons in lead 141
$\Delta S = 1$ , weak neutral currents, tests for	Energy loss rate, form factor corrections
$\Delta S = 2$ , tests for	Energy loss rate for charged particles
$\Delta S = \Delta Q$ rule in $K^*$ decay, note on	Energy loss rate in compounds
Density effect in energy loss rate $\dots$ 133	Energy loss rate for muons at high energies
Density of materials, table	$\epsilon(1200) \ [now\ called\ f_0(400-1200)]$
Density of matter, critical	$\epsilon(2150) \ [now\ called\ f_2(2150)] \ \ldots \ \ldots \ 387$
Density of matter, local	$\epsilon(2300) [now \ called \ f_4(2300)] \ \dots \ \dots \ \dots \ 390$
Density parameter of the universe, $\Omega_0$	$\epsilon$ (permittivity)
DESY databases	$\epsilon_0$ (permittivity of free space)
Detector parameters	$\widehat{\epsilon}_1, \widehat{\epsilon}_2, \widehat{\epsilon}_3$ electroweak variables
Deuterium abundance	Equivalent photon approximation
Deuteron mass	Error ellipse for multivariate Gaussian
Deuteron structure function	Error estimates in least-squares fitting 161, 162
Deviations from isotropy, cosmic background radiation 119	Error estimates in likelihood fitting
Dibaryons	Error function
(see p. VIII.118 in our 1992 edition, Phys. Rev. D45, Part II)	Error propagation
Dielectric constant of gaseous elements, table	Error propagation, straight-line fit
Differential Čerenkov detectors	Error procedure for masses and widths of meson resonances 430
Dipole moment, cosmic background radiation	Errors, treatment of
Directories, online, people, and organizations 16	Established nonets for the mesons
Disk density	Estimator, definition of
Distributions, probability, definition	$ \eta \text{ meson}  $
DORIS (DESY) collider parameters	$\eta(1295)$
Dose, radioactivity, unit of absorbed	$\eta(1440) \ [was \ \iota(1440)]$

Radiation, biological damage from chronic exposure 150	Scattering, relations for	79
Radiation, Čerenkov	Schwarzschild radius of sun 6	36
Radiation length	Scintillator parameters	12
Radiation length, approximate algorithm	Sea-level cosmic ray fluxes	22
Radiation length of materials, table	Searches:	
Radiation, lethal dose from	Axion searches	38
Radiation levels at collider detectors	Baryonium candidates	€
Radiation, long-term risk	Chargino searches	Э3
Radiation weighting factor	Color octet leptons	Э4
Radiative corrections in Standard Model	Color octet quarks	
Radioactive sources, commonly used	Compositeness, quark and lepton, searches 58, 69	99
Radioactivity and radiation protection	Excited lepton searches	)2
Radioactivity at accelerators	Familon searches	
Radioactivity, natural annual background	Fourth generation $(b')$ searches	15
Radioactivity, unit of absorbed dose	Free quark searches	16
Radioactivity, unit of activity	Gluino searches	96
Radioactivity, unit of exposure	Gluonium candidates	57
Radon, as component of natural background radioactivity 150	Goldstone boson searches	13
Random angle, Monte Carlo algorithm for sine and cosine of 168	Heavy boson searches	31
Random number generators	Heavy lepton searches	74
Rao-Cramér-Frechet bound	Heavy particle searches	96
Rapidity	Higgs searches	25
Redshift	Invisible $A^0$ (Axion) searches	15
Refractive index of materials, table	Lepton (heavy) searches	
Regge theory fits to total cross sections, table	Lepton mixing, neutrinos (massive) and, search for 23, 28	37
Relativistic kinematics	Lepton, quark compositeness searches	
Relativistic rise	Lepton, quark substructure searches	99
Relativistic transformation of electromagnetic fields	Leptoquark searches	35
Rem, roentgen equivalent for man	Light boson searches	38
Renormalization in Standard Model	Light neutrino types, number of 23, 28	36
Renormalization schemes in QCD	Magnetic monopole searches	35
Representations, $SU(n)$	Majoron searches	
Residuals, definition of	Massive neutrinos and lepton mixing, searches 23, 28	
Resistivity, electrical, of elements, table	Monopole searches	35
Resistivity of metals	Neutralino searches	
Resistivity, relations for	Neutrino oscillation searches	37
Resonance, Breit-Wigner form and Argand plot for 178	Neutrino, solar, experiments	94
Resonances (see Mesons and Baryons)	Neutrino types, number of	36
Restricted energy loss rate, charged projectiles	Neutrinoless double beta decay searches	
$\rho$ parameter in electroweak analyses	Neutrinos (massive) and lepton mixing, search for 23, 28	
$\rho$ parameter in electroweak analyses (Standard Model) 91	Non- $q\overline{q}$ candidates	
$\rho$ parameter of electroweak interactions	Other particle searches	
$\rho(770)$	Photino searches	
$\rho(770)$ , note on	Quark and lepton compositeness searches	99
$\hat{\rho}(1405)$	Quark and lepton substructure searches	
$\rho(1450)$	Quark searches, free	16
$\rho(1450)$ and $\rho(1770)$ , note on	Slepton searches	94
$\rho(1700)$	Sneutrino searches	94
$\rho(2150)$	Squark searches	95
$\rho_3(1690) \ [was \ g(1690)] \ \dots \ \dots \ \dots \ \dots \ 28, 373$	Solar $\nu$ experiments	<del>3</del> 4
$\rho_3(2250)$	Substructure, quark and lepton, searches	99
$(\rho_5(2350))$	Supersymmetric partner searches	37
Ring-Imaging Čerenkov detectors	Technipion searches	
Robertson-Walker metric	Vector meson candidates	93
Robustness of statistical estimator, definition	Weak gauge boson searches 20, 23	31
Roentgen, measure of X or $\gamma$ radiation intensity 150	$Z'$ searches, note on $\ldots \ldots	
Rydberg energy	Selection and treatment of data	
s (quark)	Semileptonic decays (B), note on	
S,T,U electroweak variables	Shower detector energy resolution	
$S = +1$ baryons ( $Z^*$ baryons)	Showers, electromagnetic, lateral distribution of	
(see p. VIII.58 in our 1992 edition, Phys. Rev. <b>D45</b> , Part II)	Showers, electromagnetic, longitudinal distribution of 13	
$S(975) \text{ or } S^* \text{ [now called } f_0(980)] \dots	SI units, complete set	
S-matrix approach to $Z$ lineshape	Sidereal day	
S-matrix for two-body scattering	Sidereal year	
Scalar mesons, note on	Sievert, unit of radiation dose equivalent	
Scale factor, definition of	$\Sigma$ baryons (see also $\Lambda$ and $\Sigma$ baryons) 53, 63	

$\Sigma_{\perp}^{+}$	Supersymmetric partner searches
$\Sigma^0$	Supersymmetry, electroweak analyses of
$\Sigma^{-}$	Superweak model of CP violation 422, 507
$\Sigma(1670)$ , note on	Survival probability, relations for
$\Sigma_c(2455)$	Synchrotron radiation
$\Sigma_c(2530)$	Systematic errors, treatment of
Silicon strip detectors	t (quark)
$\sin^2 \theta_W$ , weak mixing angle	T (time reversal), tests of conservation
Singlet-octet mixing in quark model	$\tau$ lepton
SLAC databases	au-decay branching fractions, note on
SLC (SLAC) collider parameters	au polarization in $Z$ decay
Slepton searches	Technicolor, electroweak analyses of
Sneutrino searches	Technipion searches
Software directories	TEVATRON (Fermilab) collider parameters
Solar equatorial radius	Thermal conductivity of elements, table
Solar luminosity	Thermal expansion coefficients of elements, table
Solar mass	$\theta(1690) \ [now \ called \ f_J(1710)] \ \dots \ \dots \ \dots \ 28, 379$
Solar $\nu$ experiments	$\theta_W$ , weak mixing angle
Solar radius in galaxy	Thomson cross section
Solar velocity in galaxy	Three-body decay kinematics
Sources, radioactive, commonly used	Three-body phase space
SPEAR (SLAC) collider parameters	Threshold Čerenkov detectors
Specific heats of elements, table	TMAE
Spherical harmonics	
Spin-dependent structure functions	Top quark mass from electroweak analyses
• •	• •
SPIRES database	Top quark (t)
$Sp\bar{p}S$ (CERN) collider parameters	top, $m_t$ , constraints on
Squark searches	Total cross sections, table of fit parameters
SSC collider parameters	Total cross sections, summary plot
Standard candles	Total lepton number conservation
Standard error, definition of	Transformation of electromagnetic fields, relativistic
Standard Model of electroweak interactions	Transition radiation
Standard particle numbering for Monte Carlos	Transition radiation detectors (TRD)
Statistic, definition of	Transuranium elements
Statistics	TRISTAN (KEK) collider parameters
Stefan-Boltzmann constant	Two-body decay kinematics
Stopping power	Two-body differential cross sections
Stopping power for heavy charged projectiles	Two-body partial decay rate
Straight-line fit, relations for	Two-body scattering kinematics
Strange baryons	Two-photon processes in $e^+e^-$ annihilation
Strange mesons	Tully-Fisher method
Strange quark $(s)$	Type Ia supernovae
Strangeness-changing neutral currents, tests for	Type II supernovae
Strong coupling constant in QCD	u (quark)
Structure functions	Underground cosmic rays
Structure functions, electroproduction, relations for	Unified atomic mass unit
Structure functions in quark parton model	Uniform distribution, table of
Structure functions, leptoproduction, relations for 179	Uniform probability density function
Student's t distribution, Monte Carlo algorithm for 169	Unitarity triangle
Student's t distribution, relations for	Units and conversion factors
Student's $t$ distribution, table of	Units, electromagnetic
$SU(2) \times U(1)$	Units, SI, complete set
SU(3) classification of baryon resonances	Universe, age of
SU(3) isoscalar factors	Universe, cosmological properties of
SU(3) multiplets	Universe, critical density of
SU(3) representation matrices	Universe, curvature of
SU(6) multiplets	Universe, density parameter of
SU(n) multiplets	Upper limits, Gaussian distribution
Substructure, quark and lepton, searches	Upper limits, Poisson distribution
Substructure, quark and lepton, searches, note on 699	$\Upsilon$ states, width determinations of, note on
Summary Tables, organization of	$\Upsilon(1S) = \Upsilon(9460)$
Sunyaev-Zeldovich effect	$\Upsilon(2S) = \Upsilon(10023)$
Superconducting solenoids	$\Upsilon(3S) = \Upsilon(10355)$
Supernovae, Type Ia	$\Upsilon(4S) = \Upsilon(10580)$
Supernovae, Type II	$\Upsilon(10860)$

$\Upsilon(11020)$
$V_{ud}, V_{us}, V_{ub}, V_{cd}, V_{cs}, V_{cb}, V_{td}, V_{ts}, V_{tb}$
Variance, definition
Variance, relations for
Vector meson candidates
VEPP-2m (Novosibirsk) collider parameters 129
VEPP-4m (Novosibirsk) collider parameters
W gauge boson
W boson, mass, width, branching ratios, and coupling to fermions 19, 65, 85, 89, 91
and coupling to fermions
Weak boson searches
Weak interactions of quarks and leptons
Weak mixing angle $(\sin^2 \theta_W)$
Weak neutral currents, tests for $(\Delta B = 1, \Delta C = 1, \Delta S = 1)$ 59
Weighted averaging, relations for
Weinberg angle $(\sin^2 \theta_W)$
Width determinations of $\Upsilon$ states, note on 547
Width of $W$ and $Z$ bosons
Wien displacement law constant
WIMPs (also see dark matter limits)
Wolfenstein parameterization
World-Wide Web information
x variable (of Feynman's)

$\xi(2220) \ [now\ called\ f_J(2220)] \ \dots \ \dots \ 389$
$Y^*$ resonances (see $\Lambda$ and $\Sigma$ resonances)
Year, sidereal
Year, tropical
Young diagrams
Young tableaux
Young's modulus of solid elements, table
Z gauge boson
Z boson, note on
Z decay to heavy flavors
Z boson, mass, width, branching ratios, and coupling to fermions
and coupling to fermions 19, 65, 85, 91, 232
Z width, plot
Z' searches, note on
$Z^*$ resonances ( $KN$ system)
