(Received 22 October 1997; published 19 February 1998)

In the supersymmetric extension of the standard model we derive the two-loop QCD corrections to the scalar quark contributions to the electroweak precision observables entering via the ρ parameter. A very compact expression is derived for the gluon-exchange contribution. The complete analytic result for the gluino-exchange contribution is very lengthy; we give expressions for several limiting cases that were derived from the general result. The two-loop corrections, generally of the order of 10%-30% of the one-loop contributions, can be very significant. Contrary to the standard model case, where the QCD corrections are negative and screen the one-loop value, the corresponding corrections in the supersymmetric case are in general positive, therefore increasing the sensitivity in the search for scalar quarks through their virtual effects in high-precision electroweak observables. I. INTRODUCTION

Supersymmetric (SUSY) theories [1] are widely considered as the theoretically most appealing extension of the standard model (SM). They are consistent with the approximate unification of the three gauge coupling constants at the grand unified theory (GUT) scale and provide a way to cancel the quadratic divergences in the Higgs sector, hence stabilizing the huge hierarchy between the GUT and the Fermi scales. Furthermore, in SUSY theories the breaking of the electroweak symmetry is naturally induced at the Fermi scale, and the lightest supersymmetric particle can be neutral, weakly interacting, and absolutely stable, providing therefore a natural solution for the dark matter problem; for recent reviews see, for instance, Ref. [2].

Supersymmetry predicts the existence of scalar partners \tilde{f}_L, \tilde{f}_R to each SM chiral fermion, and spin-1/2 partners to the gauge bosons and to the scalar Higgs bosons. So far, the direct search of SUSY particles at present colliders has not been successful. One can only set lower bounds of $\mathcal{O}(100)$ GeV on their masses [3]. The search for SUSY particles can be extended to slightly larger values in the next runs at the CERN e^+e^- collider LEP2 and at the upgraded Fermilab Tevatron. To sweep the entire mass range for the SUSY particles, which from naturalness arguments is expected not to be larger than the TeV scale, the higher-energy hadron or e^+e^- colliders of the next decade will be required.

An alternative way to probe SUSY is to search for the virtual effects of the additional particles. Indeed, now that the top-quark mass is known [4], and its measured value is in remarkable agreement with the one indirectly obtained from high-precision electroweak data, one can use the available data to search for the quantum effects of the SUSY particles: sleptons, squarks, gluinos, and charginos or neutralinos. In

the minimal supersymmetric standard model (MSSM) there are three main possibilities for the virtual effects of SUSY particles to be large enough to be detected in present experiments.

(i) In the rare decay $b \rightarrow s \gamma$, besides the SM top-quark– W-boson loop contribution, one has additional contributions from chargino-top-squark and charged Higgs-boson-topsquark loops [5]. These contributions can be sizable but the two new contributions can interfere destructively in large areas of the MSSM parameter space, leading in this case to a small correction to the decay rate predicted by the SM.

(ii) If charginos and scalar top quarks are light enough, they can affect the partial decay width of the Z boson into *b* quarks in a sizable way [6]. This feature has been widely discussed in the recent years, in view of the deviation of the $Z \rightarrow b\overline{b}$ partial width from the SM prediction [7]. However, for chargino and top-squark masses beyond the LEP2 or Tevatron reach, these effects become too small to be observable [7].

(iii) A third possibility is the contribution of the scalar quark loops, in particular top-squark and bottom-squark loops, to the electroweak gauge-boson self-energies [8,9]: If there is a large splitting between the masses of these particles, the contribution will grow with the square of the mass of the heaviest scalar quark and can be very large. This is similar to the SM case where the top-bottom weak isodoublet generates a quantum correction that grows as the top-quark mass squared.

In this paper, we will focus on the third possibility and discuss in detail the leading contribution of scalar quark loops to electroweak precision observables, which is parametrized by their contribution to the ρ parameter. The radiative corrections affecting the vector-boson self-energies stemming from charginos, neutralinos, and Higgs bosons have been discussed in several papers [8,9]. In the MSSM, because of the strong constraints on the Higgs sector, the propagator corrections due to Higgs particles are very close to those of the SM for a light Higgs bosons [10]. In the decoupling regime where all scalar Higgs bosons but the light-

^{*}Present address: Physik Department, Technische Universität München, D-85748 Garching, Germany.

est are very heavy, the SUSY Higgs sector is effectively equivalent to the SM Higgs sector with a Higgs-boson mass of the order of 100 GeV. The contribution of charginos and neutralinos, except from threshold effects, is also very small [9]. The main reason is that the custodial symmetry which guarantees that $\rho = 1$ at the tree level is only weakly broken in this sector since the terms which can break this symmetry in the chargino-neutralino mass matrices are all proportional to M_W and hence bounded in magnitude [9].

The propagator corrections from squark loops to the electroweak observables can be attributed, to a large extent, to the correction to the ρ parameter [11], which measures the relative strength of the neutral to charged current processes at zero momentum transfer. This is similar to the SM, where the top-bottom contribution to the precision observables is, to a very good approximation, proportional to their contribution to the deviation of the ρ parameter from unity. Further contributions, compared to the previous one, are suppressed by powers of the heavy masses. It is mainly from this contribution that the top-quark mass has been successfully predicted from the measurement of the Z-boson observables and of the W-boson mass at hadron colliders. However, in order for the predicted value to agree with the experimental one, higher-order radiative corrections [12–14] had to be included. For instance, the two-loop QCD corrections lead to a decrease of the one-loop result by approximately 10% and shift the top-quark mass upwards by an amount of ~ 10 GeV.

In order to treat the SUSY loop contributions to the electroweak observables at the same level of accuracy as the standard contribution, higher-order corrections should be incorporated. In particular the QCD corrections, which because of the large value of the strong coupling constant can be rather important, must be known. In a short Letter [15] we have recently presented the results for the $\mathcal{O}(\alpha_s)$ correction to the contribution of the scalar top- and bottom-quark loops to the ρ parameter. In this article we give the main details of the calculation and present the explicit result for the gluon-exchange contribution in several limiting cases.

The paper is organized as follows. In the next section, we summarize the one-loop results and fix the notation. The

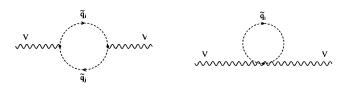

FIG. 1. Feynman diagrams for the contribution of scalar quark loops to the gauge boson self-energies at one-loop order.

main features of the two-loop calculation are discussed in Sec. III. In Sec. IV a compact expression is given for the gluon-exchange contributions. The results for the gluino-exchange contributions are presented for the limiting cases of zero gluino mass and a very heavy gluino as well as for the case of arbitrary gluino mass but vanishing squark mixing. Effects of $\mathcal{O}(\alpha_s)$ corrections to relations between the squark masses existing in different scenarios are discussed. In Sec. V we give our conclusions.

II. ONE-LOOP RESULTS

For the sake of completeness, we summarize in this section the one-loop contribution of a squark doublet to the electroweak precision observables. Before that, to set the notation, we first discuss the masses and couplings of scalar quarks in the MSSM.

As mentioned previously, SUSY associates a left- and a right-handed scalar partner to each SM quark. The current eigenstates \tilde{q}_L and \tilde{q}_R mix to give the mass eigenstates \tilde{q}_1 and \tilde{q}_2 ; the mixing angle is proportional to the quark mass and is therefore important only in the case of the third generation squarks. In the MSSM, the squark masses are given in terms of the Higgs-Higgsino mass parameter μ , the ratio of the vacuum expectation values $\tan\beta$ of the two-Higgs-doublet MSSM fields needed to break the electroweak symmetry, the left- and right-handed scalar masses $M_{\tilde{q}_L}$ and $M_{\tilde{q}_R}$, and the soft-SUSY-breaking trilinear coupling A_q . The top- and bottom-squark mass eigenstates and their mixing angles are determined by diagonalizing the following mass matrices:

$$\mathcal{M}_{\tilde{t}}^{2} = \begin{pmatrix} M_{\tilde{t}_{L}}^{2} + m_{t}^{2} + \cos 2\beta \left(\frac{1}{2} - \frac{2}{3}s_{W}^{2}\right) M_{Z}^{2} & m_{t}M_{t}^{LR} \\ \\ m_{t}M_{t}^{LR} & M_{\tilde{t}_{R}}^{2} + m_{t}^{2} + \frac{2}{3}\cos 2\beta \ s_{W}^{2}M_{Z}^{2} \end{pmatrix},$$
(1)

$$\mathcal{M}_{\tilde{b}}^{2} = \begin{pmatrix} M_{\tilde{b}_{L}}^{2} + m_{b}^{2} + \cos 2\beta \left(-\frac{1}{2} + \frac{1}{3}s_{W}^{2} \right) M_{Z}^{2} & m_{b}M_{b}^{LR} \\ \\ m_{b}M_{b}^{LR} & M_{\tilde{b}_{R}}^{2} + m_{b}^{2} - \frac{1}{3}\cos 2\beta \ s_{W}^{2}M_{Z}^{2} \end{pmatrix},$$
(2)

with $M_t^{LR} = A_t - \mu \cot\beta$ and $M_b^{LR} = A_b - \mu \tan\beta$; $s_W^2 = 1 - c_W^2 \equiv \sin^2\theta_W$. Furthermore, SU(2) gauge invariance requires $M_{\tilde{t}_L} = M_{\tilde{b}_L}$ at the tree level. Expressed in terms of the squark masses $m_{\tilde{q}_1}, m_{\tilde{q}_2}$ and the mixing angle $\theta_{\tilde{q}}$ the squark mass matrices read

$$\mathcal{M}_{\tilde{q}}^{2} = \begin{pmatrix} \cos^{2}\theta_{\tilde{q}}m_{\tilde{q}_{1}}^{2} + \sin^{2}\theta_{\tilde{q}}m_{\tilde{q}_{2}}^{2} & \sin\theta_{\tilde{q}}\cos\theta_{\tilde{q}}(m_{\tilde{q}_{1}}^{2} - m_{\tilde{q}_{2}}^{2}) \\ \sin\theta_{\tilde{q}}\cos\theta_{\tilde{q}}(m_{\tilde{q}_{1}}^{2} - m_{\tilde{q}_{2}}^{2}) & \sin^{2}\theta_{\tilde{q}}m_{\tilde{q}_{1}}^{2} + \cos^{2}\theta_{\tilde{q}}m_{\tilde{q}_{2}}^{2} \end{pmatrix}.$$
(3)

Because of the large value of the top-quark mass m_t , the mixing between the left- and right-handed top squarks \tilde{t}_L and \tilde{t}_R can be very large, and after diagonalization of the mass matrix the lightest scalar top-quark mass eigenstate \tilde{t}_1 can be much lighter than the top quark and all the scalar partners of the light quarks [16]. The mixing in the bottom-squark sector is in general rather small, except if A_b, μ , or tan β are extremely large. In most of our discussion we will assume that, because of the small bottom-quark mass, the mixing in the bottom-squark sector is negligible and therefore $\tilde{b}_L \equiv \tilde{b}_1$.

Using the notation of the first generation, the contribution of a squark doublet \tilde{u}, \tilde{d} to the self-energy of a vector boson $V \equiv \gamma, Z, W$ and to the $Z \cdot \gamma$ mixing is given by the diagrams of Fig. 1. Summing over all possible flavors and helicities, the squark contribution to the transverse parts of the gauge-boson self-energies at arbitrary momentum transfer q^2 can be written, in terms of the Fermi constant G_F , as follows:

$$\Pi_{WW}(q^{2}) = -\frac{3G_{F}M_{W}^{2}}{8\sqrt{2}\pi^{2}} \sum_{i,j=1,2} g_{W\tilde{u}_{i}\tilde{d}_{j}}^{2} \Pi_{0}(q^{2}, m_{\tilde{u}_{i}}^{2}, m_{\tilde{d}_{j}}^{2}),$$

$$\Pi_{ZZ}(q^{2}) = -\frac{3G_{F}M_{Z}^{2}}{4\sqrt{2}\pi^{2}} \sum_{\substack{\tilde{q}=\tilde{u},\tilde{d}\\i,j=1,2}} g_{Z\tilde{q}_{i}\tilde{q}_{j}}^{2} \Pi_{0}(q^{2}, m_{\tilde{q}_{i}}^{2}, m_{\tilde{q}_{j}}^{2}),$$

$$\Pi_{Z\gamma}(q^{2}) = -\frac{3G_{F}M_{Z}^{2}s_{W}c_{W}}{4\sqrt{2}\pi^{2}} \sum_{\substack{\tilde{q}=\tilde{u},\tilde{d}\\i=1,2}} g_{Z\tilde{q}_{i}\tilde{q}_{j}}e_{\tilde{q}_{i}}\Pi_{0}(q^{2}, m_{\tilde{q}_{i}}^{2}, m_{\tilde{q}_{i}}^{2}),$$

$$\Pi_{\gamma\gamma}(q^{2}) = -\frac{3G_{F}M_{Z}^{2}s_{W}^{2}c_{W}}{4\sqrt{2}\pi^{2}} \sum_{\substack{\tilde{q}=\tilde{u},\tilde{d}\\i=1,2}} e_{\tilde{q}_{i}}^{2} \Pi_{0}(q^{2}, m_{\tilde{q}_{i}}^{2}, m_{\tilde{q}_{i}}^{2}),$$
(4)

with the reduced couplings of the squarks to the W and Z bosons, including mixing $\theta_{\tilde{q}}$ between left- and right-handed squarks, given by (e_q and I_3^q are the electric charge and the weak isospin of the partner quark)

$$g_{W\tilde{u}_{i}\tilde{d}_{j}} = \begin{pmatrix} \cos\theta_{\tilde{u}}\cos\theta_{\tilde{d}} & -\cos\theta_{\tilde{u}}\sin\theta_{\tilde{d}} \\ -\cos\theta_{\tilde{u}}\sin\theta_{\tilde{d}} & \sin\theta_{\tilde{u}}\sin\theta_{\tilde{d}} \end{pmatrix},$$

$$g_{Z\tilde{q}_{i}\tilde{q}_{j}} = \begin{pmatrix} (I_{3}^{q} - e_{q}s_{W}^{2})\cos^{2}\theta_{\tilde{q}} - e_{q}s_{W}^{2}\sin^{2}\theta_{\tilde{q}} & -I_{3}^{q}\sin\theta_{\tilde{q}}\cos\theta_{\tilde{q}} \\ -I_{3}^{q}\sin\theta_{\tilde{q}}\cos\theta_{\tilde{q}} & -e_{q}s_{W}^{2}\cos^{2}\theta_{\tilde{q}} + (I_{3}^{q} - e_{q}s_{W}^{2})\sin^{2}\theta_{\tilde{q}} \end{pmatrix}.$$
(5)

In both the dimensional regularization [17] and dimensional reduction [18] schemes,¹ the function $\Pi_0(q^2, m_a^2, m_b^2)$ reads

$$\Pi_{0}(q^{2},m_{a}^{2},m_{b}^{2}) = \frac{4}{3} \left[m_{a}^{2} + m_{b}^{2} - \frac{q^{2}}{3} + \left(m_{a}^{2} + m_{b}^{2} - \frac{q^{2}}{2} - \frac{(m_{a}^{2} - m_{b}^{2})^{2}}{2 q^{2}} \right) B_{0}(q^{2},m_{a},m_{b}) + \frac{m_{a}^{2} - m_{b}^{2}}{2 q^{2}} \left[A_{0}(m_{a}) - A_{0}(m_{b}) \right] - A_{0}(m_{a}) - A_{0}(m_{b}) \right].$$

$$(6)$$

The Passarino-Veltman one- and two-point functions [19] are defined as

$$A_{0}(m) = m^{2} \left[\frac{1}{\epsilon} + 1 - \ln \frac{m^{2}}{\mu^{2}} + \epsilon \left(1 + \frac{\pi^{2}}{12} - \ln \frac{m^{2}}{\mu^{2}} + \frac{1}{2} \ln^{2} \frac{m^{2}}{\mu^{2}} \right) \right],$$

$$B_{0}(q^{2}, m_{a}, m_{b}) = \frac{1}{\epsilon} + B_{0}^{\text{fin}}(q^{2}, m_{a}, m_{b}) + \epsilon B_{0}^{\epsilon}(q^{2}, m_{a}, m_{b}),$$
(7)

¹In general the dimensional reduction scheme, which preserves SUSY, should be used. For all quantities considered in this paper dimensional reduction yields precisely the same result as dimensional regularization (see, however, the discussion in Sec. IV D).

$$B_0^{\text{fin}}(q^2, m_a, m_b) = 2 - \ln \frac{m_a m_b}{\mu^2} + \frac{m_a^2 - m_b^2}{q^2} \ln \frac{m_a}{m_b} + \frac{\beta^{1/2}(q^2, m_a^2, m_b^2)}{q^2} \ln \frac{m_a^2 + m_b^2 - q^2 + \beta^{1/2}(q^2, m_a^2, m_b^2)}{2m_a m_b},$$

where μ is the renormalization scale, β the phase space function,

$$\beta(q^2, m_a^2, m_b^2) = q^2 - m_a^2 - m_b^2 + \frac{(m_a^2 - m_b^2)^2}{q^2}, \qquad (8)$$

and $2\epsilon = 4 - n$ with *n* the space-time dimension. We have absorbed a factor $(e^{\gamma/4\pi})^{\epsilon}$, with γ the Euler constant, in the 't Hooft scale μ to prevent uninteresting combinations of $\ln 4\pi, \gamma, \ldots$ in our results. The explicit form of the function B_0^{ϵ} is not needed for our purposes but can be found in Ref. [20].

At zero momentum-transfer, $q^2=0$, the function Π_0 is finite and reduces to

$$F_0(m_a^2, m_b^2) \equiv \Pi_0(0, m_a^2, m_b^2) = m_a^2 + m_b^2 - \frac{2m_a^2 m_b^2}{m_a^2 - m_b^2} \ln \frac{m_a^2}{m_b^2}.$$
(9)

We now focus on the contribution of a squark doublet to the ρ parameter. It is well known that the deviation of the ρ parameter from unity parametrizes the leading universal corrections induced by heavy fields in electroweak amplitudes. It is due to a mass splitting between the fields in an isospin doublet. Compared to this correction all additional contributions are suppressed. In the relevant cases of the W-boson mass and of the effective weak mixing angle $\sin^2 \theta_W^{\text{eff}}$, for example, a doublet of heavy squarks would induce shifts proportional to its contribution to ρ ,

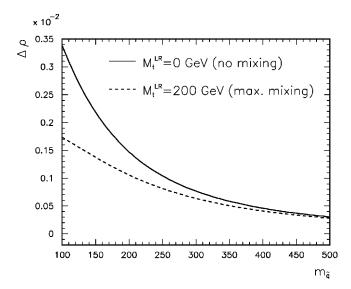

FIG. 2. One-loop contribution of the (\tilde{t}, \tilde{b}) doublet to $\Delta \rho$ as a function of the common squark mass $m_{\tilde{q}}$ for $\theta_{\tilde{t}}=0$ and $\theta_{\tilde{t}} \sim -\pi/4$ (with tan β =1.6, $M_b^{LR}=0$, and $M_t^{LR}=0$ or 200 GeV).

$$\delta M_W \approx \frac{M_W}{2} \frac{c_W^2}{c_W^2 - s_W^2} \Delta \rho, \quad \delta \sin^2 \theta_W^{\text{eff}} \approx -\frac{c_W^2 s_W^2}{c_W^2 - s_W^2} \Delta \rho.$$
(10)

In terms of the transverse parts of the W- and Z-boson self-energies at zero momentum transfer, the squark loop contribution to the ρ parameter is given by

$$\rho = \frac{1}{1 - \Delta \rho}, \quad \Delta \rho = \frac{\Pi_{ZZ}(0)}{M_Z^2} - \frac{\Pi_{WW}(0)}{M_W^2}.$$
(11)

Using the previous expressions for the W- and Z-boson selfenergies and neglecting the mixing in the bottom-squark sector, one obtains, for the contribution of the \tilde{t}/\tilde{b} doublet at one-loop order (only the left-handed sbottom \tilde{b}_L contributes for $\theta_{\tilde{b}}=0$),

$$\Delta \rho_0^{\text{SUSY}} = \frac{3G_F}{8\sqrt{2}\pi^2} [-\sin^2\theta_{\tilde{t}}\cos^2\theta_{\tilde{t}} F_0(m_{\tilde{t}_1}^2, m_{\tilde{t}_2}^2) +\cos^2\theta_{\tilde{t}} F_0(m_{\tilde{t}_1}^2, m_{\tilde{b}_L}^2) + \sin^2\theta_{\tilde{t}} F_0(m_{\tilde{t}_2}^2, m_{\tilde{b}_L}^2)].$$
(12)

The function F_0 vanishes when the two squarks running in the loop are degenerate in mass, $F_0(m_q^2, m_q^2) = 0$. In the limit of large squark mass splitting it becomes proportional to the heavy squark mass squared: $F_0(m_a^2, 0) = m_a^2$. Therefore, the contribution of a squark doublet becomes in principle very large when the mass splitting between squarks is large. This is exactly the same situation as in the case of the SM where the top-bottom contribution to the ρ parameter at one-loop order, keeping both the t and b quark masses, reads [11]

$$\Delta \rho_0^{\rm SM} = \frac{3G_F}{8\sqrt{2}\pi^2} F_0(m_t^2, m_b^2).$$
(13)

For $m_t \ge m_b$ this leads to the well-known quadratic correction $\Delta \rho_0^{\text{SM}} = 3G_F m_t^2 / (8\sqrt{2}\pi^2)$.

In Fig. 2 we display the one-loop correction to the ρ parameter that is induced by the \tilde{t}/\tilde{b} isodoublet. The scalar mass parameters are assumed to be equal, $M_{\tilde{t}_L} = M_{\tilde{t}_R}$ and $M_{\tilde{b}_L} = M_{\tilde{b}_R}$, as is approximately the case in supergravity models with scalar mass unification at the GUT scale [21]. As mentioned above, SU(2) gauge invariance requires at the tree level² $M_{\tilde{t}_L} = M_{\tilde{b}_L}$, yielding in this case $M_{\tilde{t}_L} = M_{\tilde{t}_R} = M_{\tilde{b}_L} = M_{\tilde{b}_R} = m_{\tilde{q}}$. In this scenario, the scalar top-quark mixing angle is either very small, $\theta_{\tilde{t}} \sim 0$, or almost maximal, $\theta_{\tilde{t}} \sim -\pi/4$, in most of the MSSM parameter space. The contribution $\Delta \rho_0^{\text{SUSY}}$ is shown as a function of the common squark mass $m_{\tilde{q}}$ for tan $\beta = 1.6$ for the two cases $M_t^{LR} = 0$ (no

²The corrections to the relations between the squark masses will be discussed in Sec. IV D.

mixing) and $M_t^{LR} = 200 \text{ GeV}$ (maximal mixing);³ the bottomquark mass and therefore the mixing in the bottom-squark sector are neglected, leading to $m_{\tilde{b}_L} = m_{\tilde{b}_1} \simeq m_{\tilde{q}}$. Here and in all the numerical calculations in this paper we use $m_t = 175$ GeV, $M_Z = 91.187$ GeV, $M_W = 80.33$ GeV, and $\alpha_s = 0.12$. The electroweak mixing angle is defined from the ratio of the vector boson masses: $s_W^2 = 1 - M_W^2/M_Z^2$.

As can be seen, the correction is rather large for small $m_{\tilde{q}}$, exceeding the level $\Delta \rho = 1.3 \times 10^{-3}$ of experimental sensitivity⁴ in the case of no mixing for $m_{\tilde{q}} \sim 150$ GeV, which corresponds to the experimental lower bound on the common squark mass [3], and getting very close to it in the case of maximal mixing. For large $m_{\tilde{q}}$ values, the two top-squark and the bottom-squark masses are approximately degenerate since $m_{\tilde{q}} \gg m_t$, and the contribution to $\Delta \rho$ becomes very small.

For illustration, we have chosen the value $\tan\beta = 1.6$ which is favored by $b \cdot \tau$ Yukawa coupling unification scenarios [21]. In fact, the analysis depends only marginally on $\tan\beta$ if M_t^{LR} (and not A_t and μ) is used as input parameter. The only effect of varying $\tan\beta$ is then to slightly alter the D terms in the mass matrices Eqs. (1) and (2), which does not change the situation in a significant way. However, for large $\tan\beta$ values, $\tan\beta \sim m_t/m_b$, the mixing in the bottom-squark sector has to be taken into account, rendering the analysis somewhat more involved. We will focus on the scenario with a low value of $\tan\beta$ in the following.

In Fig. 3 we display $\Delta \rho_0^{\text{SUSY}}$ as a function of the mixing angle for three values of the common squark mass, $m_{\tilde{q}}$ = 150, 250, and 500 GeV, and for $\tan\beta$ =1.6. The contribution is practically flat except for values of the mixing angle very close to the lower limit, $\theta_{\tilde{q}} \sim -\pi/4$. This justifies the choice of concentrating on the two extreme cases. In fact, in the case $M_{\tilde{t}_L} = M_{\tilde{t}_R}$, the maximal mixing scenario $\theta_{\tilde{q}}$ = $-\pi/4$ is only obtained exactly when the D terms are set to zero, which is the case when $\tan\beta$ =1. One can also have maximal mixing if the sums of $M_{\tilde{t}_L}^2$ and $M_{\tilde{t}_R}^2$ with their corresponding D terms are equal, making the diagonal entries in the mass matrices, Eqs. (1) and (2), identical.

The parameter M_t^{LR} not only influences the mixing but also the mass splitting between the scalar top quarks. The effect of varying M_t^{LR} on $\Delta \rho_0^{\text{SUSY}}$ is displayed in Table I for the case of exact maximal mixing, i.e., $\tan \beta = 1$. The scenario with $\tan \beta = 1.6$ yields similar numerical results. For

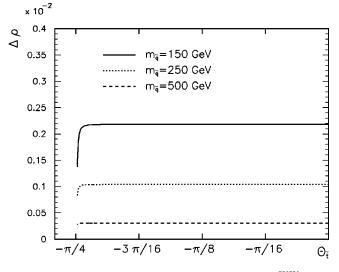

FIG. 3. Dependence of the one-loop contribution $\Delta \rho_0^{\text{SUSY}}$ on the top-squark mixing angle $\theta_{\tilde{t}}$. The parameters are the same as in Fig. 2.

large values of M_t^{LR} the contribution to the ρ parameter can become huge, exceeding by far the level of experimental observability. The increase of $\Delta \rho_0^{\text{SUSY}}$ with larger values of M_t^{LR} is due to the increased mass splitting between the two top-squark masses and $m_{\tilde{b}_1}$ that is induced for $m_t M_t^{LR}$ $\gg m_{\tilde{q}}^2$. For values of $m_{\tilde{q}}$ comparable to the top-quark mass, $m_{\tilde{q}} \leq 200$ GeV, the mass splitting is already large even for small M_t^{LR} due to the additional m_t^2 term in the top-squark mass matrix; this is similar to the no-mixing case.

If the GUT relation $M_{\tilde{t}_L} \simeq M_{\tilde{t}_R}$ is relaxed and large values of the mixing parameter M_t^{LR} are assumed, the splitting between the top-squark and bottom-squark masses is so large that the contribution to the ρ parameter can become even bigger than in the previously discussed scenario (see Sec. IV D for a more detailed discussion).

III. TWO-LOOP CALCULATION

The QCD corrections to the squark contributions to the vector-boson self-energies, Fig. 4, can be divided into three

TABLE I. $\Delta \rho_0^{\text{SUSY}}$ in units of 10^{-3} for several values of $m_{\tilde{q}}$ and M_t^{LR} (in GeV) and $\tan \beta = 1$. The values of M_t^{LR} are chosen such that the corresponding squark masses lie in the experimentally allowed range.

$m_{\tilde{q}}$ (GeV)	M_t^{LR} (GeV)	$\Delta ho_0^{ m SUSY} imes 10^{-3}$
200	100	1.68
	200	1.35
	300	0.89
	400	1.28
500	200	0.34
	500	0.23
	1400	2.04
	1550	4.97
800	500	0.12
	1500	0.07
	2000	0.30
	3700	15.8

³As will be discussed below, the case of exact maximal mixing, $\theta_{\tilde{t}} = -\pi/4$, is not possible in the scenario with $M_{\tilde{t}_L} = M_{\tilde{t}_R}$ and $\tan\beta = 1.6$. Since $\theta_{\tilde{t}}$ is already very close to the maximal value for $M_t^{LR} = 200$ GeV, we will in the following refer to this scenario as "maximal mixing."

⁴The correction to $\Delta \rho$ discussed here directly corresponds to a correction to the effective parameter *T* defined in Ref. [22] or, equivalently, to ϵ_1 as given in Ref. [23] or the combination of parameters defined in Ref. [24]. Using the 1997 precision data, the resolution on ϵ_1 is estimated to be 1.3×10^{-3} [25]. A similar estimate can be readily obtained using the present experimental errors on the world average [26] of M_W , 80 MeV, and $\sin^2 \theta_W^{\text{eff}}$, 2.2 $\times 10^{-4}$, in Eq. (10).

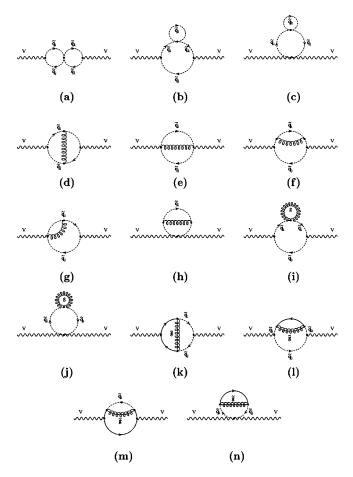

FIG. 4. Feynman diagrams for the contribution of scalar quark loops to the gauge-boson self-energies at two-loop order.

different classes: the pure scalar diagrams (Figs. 4a–4c), the gluon-exchange diagrams (Figs. 4d–4j), and the gluino-exchange diagrams (Figs. 4k–4n). These diagrams have to be supplemented by counterterms for the squark and quark mass renormalization (Figs. 5a–5c) as well as for the renormalization of the squark mixing angle (Fig. 5d). The three different sets of contributions together with the respective counterterms are separately gauge invariant and ultraviolet finite. For the gluon-exchange contribution we have only considered the squark loops, since the gluon exchange in quark loops is just the SM contribution, yielding the result $\Delta \rho_1^{SM} = -\Delta \rho_0^{SM\frac{2}{3}} (\alpha_s / \pi) (1 + \pi^2/3)$ [12].

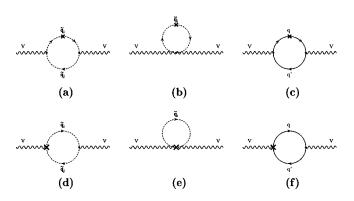

FIG. 5. Counterterm contributions to the gauge-boson selfenergies at two-loop order.

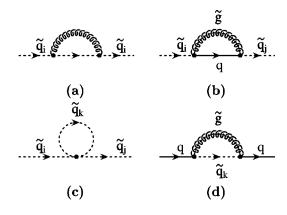

FIG. 6. One-loop diagrams contributing to the squark mass and mixing angle counterterms.

As mentioned above, the results presented in the following are precisely the same in dimensional regularization as in dimensional reduction. The renormalization procedure is performed as follows. We work in the on-shell scheme where the quark and squark masses are defined as the real part of the pole of the corresponding propagators. One further needs a prescription for the renormalization of the squark mixing angle. The renormalized mixing angle can be defined by requiring that the renormalized squark mixing self-energy $\Pi_{\tilde{q}_1\tilde{q}_2}^{\text{ren}}(q^2)$ vanish at a given momentum transfer q_0^2 , for example when one of the two squarks is on shell. This means that the two squark mass eigenstates $\widetilde{q_1}$ and $\widetilde{q_2}$ do not mix but propagate independently for this value of q^2 . Expressing the parameters in Eq. (3) by renormalized quantities and choosing the field renormalization of the squarks appropriately, this renormalization condition yields, for the mixing angle counterterm,

$$\delta\theta_{\tilde{q}}(q_0^2) = \frac{1}{m_{\tilde{q}_1}^2 - m_{\tilde{q}_2}^2} \Pi_{\tilde{q}_1 \tilde{q}_2}(q_0^2).$$
(14)

Finally, we have also included, as a check, the field renormalization constants of the quarks and the squarks in our calculation; they of course have to drop out in the final result, which we have verified by explicit calculation.

The one-loop diagrams of Figs. 6a–6c provide the renormalization of the squark masses and the squark wave functions. As the one-loop squark contributions to the vector boson self-energies are finite at vanishing external momentum [see Eq. (9)], we notice that the $O(\epsilon)$ part of the squark mass counterterm is not needed. We have contributions from the three diagrams of Figs. 6a, 6b, and 6c involving gluon exchange, gluino exchange, and a pure scalar contribution, respectively. The explicit form of the pure scalar contribution is not needed as we will see later. The contribution of the gluon exchange to the squark mass counterterm is given by

$$m_{\tilde{q}_i}\delta^g m_{\tilde{q}_i} = -\frac{\alpha_s}{2\pi}m_{\tilde{q}_i}^2 \left[\frac{1}{\epsilon} + \frac{7}{3} - \ln\frac{m_{\tilde{q}_i}^2}{\mu^2}\right], \qquad (15)$$

while the one of the gluino exchange reads

$$m_{\tilde{q}_{i}}\delta^{\tilde{g}}m_{\tilde{q}_{i}} = -\frac{\alpha_{s}}{3\pi} [(m_{q}^{2} + m_{\tilde{g}}^{2} - m_{\tilde{q}_{i}}^{2}) \quad B_{0}(m_{\tilde{q}_{i}}^{2}, m_{q}, m_{\tilde{g}}) + A_{0}(m_{\tilde{g}}) + A_{0}(m_{q}) + 2(-1)^{i} \sin 2\theta_{\tilde{q}} \quad m_{\tilde{g}}m_{q} \quad B_{0}(m_{\tilde{q}_{i}}^{2}, m_{q}, m_{\tilde{g}})],$$
(16)

where A_0 and B_0 have been defined previously, and are needed only up to O(1) in the ϵ expansion. Although in our renormalization scheme the contribution of the quarticsquark interaction to the squark masses drops out in the final result, we will also give its expression for later convenience (i'=3-i):

$$m_{\tilde{q}_i}\delta^{\tilde{q}}m_{\tilde{q}_i} = \frac{\alpha_s}{6\pi} [\cos^2 2\theta_{\tilde{q}}A_0(m_{\tilde{q}_i}) + \sin^2 2\theta_{\tilde{q}}A_0(m_{\tilde{q}_{i'}})].$$
(17)

Concerning the quark mass counterterm, Fig. 6d, in principle the $O(\epsilon)$ term is needed because the quark loop contributions to the vector-boson self-energies are ultraviolet divergent even at $q^2=0$. However, in $\Delta \rho$ this contribution drops out as the one-loop quark contribution to this physical quantity is finite. As mentioned above, the gluon contribution to the quark mass counterterm is only relevant for the pure SM correction and is not needed in the present context. The gluino contribution can be expressed as

$$\delta^{\tilde{g}}m_{q} = \frac{\alpha_{s}}{3\pi_{i}}\sum_{i=1,2} \left\{ (-1)^{i} \sin 2\theta_{\tilde{q}} \ m_{\tilde{g}} \ B_{0}(m_{q}^{2}, m_{\tilde{g}}, m_{\tilde{q}_{i}}) + \frac{1}{2m_{q}} [(m_{q}^{2} + m_{\tilde{g}}^{2} - m_{\tilde{q}_{i}}^{2})B_{0}(m_{q}^{2}, m_{\tilde{g}}, m_{\tilde{q}_{i}}) + A_{0}(m_{\tilde{q}_{i}}) - A_{0}(m_{\tilde{g}})] \right\}.$$
(18)

Finally, the counterterm for the squark mixing angle, defined at a given q_0^2 , is given by

$$\delta\theta_{\tilde{t}}(q_0^2) = \frac{\alpha_s}{3\pi} \frac{\cos 2\theta_{\tilde{t}}}{m_{\tilde{t}_1}^2 - m_{\tilde{t}_2}^2} \{4m_t m_{\tilde{g}} B_0(q_0^2, m_t, m_{\tilde{g}}) + \sin 2\theta_{\tilde{t}} [A_0(m_{\tilde{t}_2}) - A_0(m_{\tilde{t}_1})]\}.$$
(19)

As discussed above, for the value of q_0^2 one can either choose $m_{\tilde{t}_1}^2$ or $m_{\tilde{t}_2}^2$, the difference being very small. In our analysis we have chosen $q_0^2 = m_{\tilde{t}_1}^2$. This renormalization condition is equivalent to the one used in Ref. [27] for scalar quark decays.

Let us now discuss the separate contributions of the various diagrams. The contribution of the pure scalar diagrams vanishes, while for the gluon-exchange diagrams one needs to calculate only the first four genuine two-loop diagrams, Figs. 4d–4g, and the corresponding counterterm with the mass renormalization insertion, Fig. 5a. The other diagrams do not contribute for the following reasons.

(a) The diagram in Fig. 4h is exactly canceled by the corresponding diagram with the mass counterterm insertion,

Fig. 5b. It should be noted that the expression for B_0^{ϵ} is needed in order to obtain this result.

(b) The reducible diagram of Fig. 4a involving the quartic squark interaction contributes only to the longitudinal components of the vector-boson self-energies and can therefore be discarded.

(c) The diagrams in Figs. 4b and 4c are canceled by the corresponding diagrams with the counterterms, Figs. 5a and 5b, for mass renormalization (for the diagonal terms) and mixing angle renormalization (for the nondiagonal terms). The diagrams in Figs. 5d–5f for the vertex corrections contain only field renormalization constants which drop out in the final result.

(d) The gluon tadpolelike diagrams of Figs. 4i and 4j give a vanishing contribution in both dimensional regularization and reduction.

For the gluino-exchange diagrams, one has to calculate all diagrams of the types shown in Figs. 4k–4n and their corresponding counterterm diagrams depicted in Fig. 5.

We now briefly describe the evaluation of the two-loop diagrams. As explained above, we have both irreducible two-loop diagrams at zero momentum transfer and counterterm diagrams. After reducing their tensor structure, they can be decomposed into two-loop scalar integrals at zero momentum transfer (vacuum integrals) and products of one-loop integrals. The vacuum integrals are known for arbitrary internal masses and admit a compact representation for $\epsilon \rightarrow 0$ in terms of logarithms and dilogarithms (see, for instance, Ref. [28]), while the one-loop integrals A_0, B_0 are well known [see Eq. (7)]. We have used two independent implementations of the various steps of this procedure and obtained identical results.

In the first implementation, the diagrams were generated with the MATHEMATICA package FEYNARTS [29]. The model file contains, in addition to the SM propagators and vertices, the relevant part of the MSSM Lagrangian, i.e., all SUSY propagators $(\tilde{t}_1, \tilde{t}_2, \tilde{b}_1, \tilde{b}_2, \tilde{g})$ needed for the QCD corrections and the appropriate vertices (gauge-boson-squark vertices, squark-gluon and squark-gluino vertices). The program inserts propagators and vertices into the graphs in all possible ways and creates the amplitudes including all symmetry factors. The evaluation of the two-loop diagrams and counterterms was performed with the MATHEMATICA package TWOCALC [30]. By means of two-loop tensor integral decompositions it reduces the amplitudes to a minimal set of standard scalar integrals, consisting in this case of the basic oneloop functions A_0, B_0 (the B_0 functions originate from the counterterm contributions only) and the genuine two-loop function T_{134} [28], i.e., the two-loop vacuum integral. As a check of our calculation, the transversality of the two-loop photon and γZ mixing self-energies at arbitrary momentum transfer and the vanishing of their transverse parts at $q^2=0$ was explicitly verified with TWOCALC. Inserting the explicit expressions for A_0, B_0, T_{134} in the result for $\Delta \rho$, the cancellation of the $1/\epsilon^2$ and $1/\epsilon$ poles was checked algebraically, and a result in terms of logarithms and dilogarithms was derived. From this output a FORTRAN code was created which allows a fast calculation for a given set of parameters.

In the second implementation, completely independent, the diagrams were not generated automatically, but the analytic simplifications and the expansions in the limiting cases (small and large gluino mass, maximal and minimal mixing) were carried out by using the MATHEMATICA package

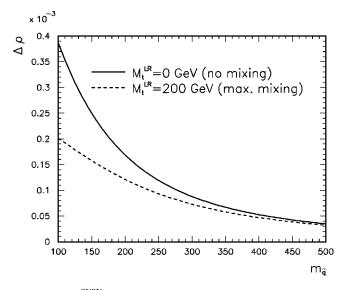

FIG. 7. $\Delta \rho_{1,\text{gluon}}^{\text{SUSY}}$ as a function of $m_{\tilde{q}}$ for the scenarios of Fig. 2.

PROCESSDIAGRAM [31]. In this way the results can be cast into a relatively compact form, shown in the following.

IV. TWO-LOOP RESULTS

A. Gluon exchange

In order to discuss our results, let us first concentrate on the contribution of the gluonic corrections and the corresponding counterterms. At the two-loop level, the results for the electroweak gauge-boson self-energies at zero momentum transfer have very simple analytical expressions. In the case of an isodoublet (\tilde{u}, \tilde{d}) where general mixing is allowed, the structure is similar to Eqs. (4) and (9) with the $g_V \tilde{q}_i \tilde{q}_i$ as given previously:

$$\Pi_{WW}(0) = -\frac{G_F M_W^2 \alpha_s}{4\sqrt{2} \pi^3} \sum_{i,j=1,2} g_{W\tilde{u}_i \tilde{d}_j}^2 F_1(m_{\tilde{u}_i}^2, m_{\tilde{d}_j}^2),$$

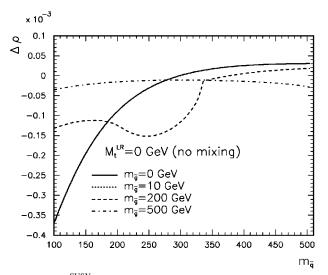

FIG. 8. $\Delta \rho_{1,\text{gluino}}^{\text{SUSY}}$ as a function of $m_{\tilde{q}}$ in the no-mixing scenario; $\tan \beta = 1.6$ and $m_{\tilde{g}} = 0$, 10 (the plots are indistinguishable), 200, and 500 GeV.

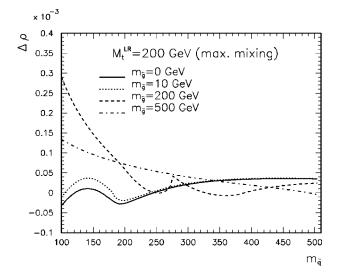

FIG. 9. $\Delta \rho_{1,\text{gluino}}^{\text{SUSY}}$ as a function of $m_{\tilde{q}}$ in the maximal mixing scenario; $\tan \beta = 1.6$ and $m_{\tilde{g}} = 0$, 10, 200, and 500 GeV.

$$\Pi_{ZZ}(0) = -\frac{G_F M_Z^2 \alpha_s}{2\sqrt{2}\pi^3} \sum_{\substack{\tilde{q}=\tilde{u},\tilde{d}\\i,j=1,2}} g_{Z\tilde{q}_i\tilde{q}_j}^2 F_1(m_{\tilde{q}_i}^2, m_{\tilde{q}_j}^2).$$
(20)

The two-loop function $F_1(x,y)$ is given in terms of dilogarithms by

$$F_{1}(x,y) = x + y - 2\frac{xy}{x-y}\ln\frac{x}{y} \left[2 + \frac{x}{y}\ln\frac{x}{y}\right] + \frac{(x+y)x^{2}}{(x-y)^{2}}\ln^{2}\frac{x}{y} - 2(x-y)\operatorname{Li}_{2}\left(1 - \frac{x}{y}\right).$$
(21)

This function is symmetric in the interchange of x and y. As in the case of the one-loop function F_0 , it vanishes for de-

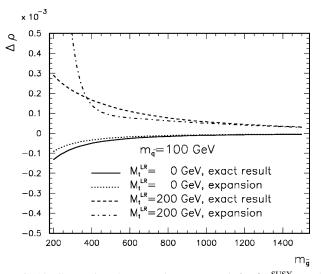

FIG. 10. Comparison between the exact result for $\Delta \rho_{1,\text{gluino}}^{\text{SUSY}}$ and the result of the expansion, Eq. (24), up to $\mathcal{O}(1/m_{\tilde{g}}^3)$ for the two scenarios of Fig. 2; $m_{\tilde{g}} = 100$ GeV.

generate masses, $F_1(x,x) = 0$, while in the case of large mass splitting it increases with the heavy scalar quark mass squared: $F_1(x,0) = x(1 + \pi^2/3)$.

From the previous expressions, the contribution of the (\tilde{t}, \tilde{b}) doublet to the ρ parameter, including the two-loop gluon exchange and pure scalar quark diagrams are obtained straightforwardly. In the case where the \tilde{b} mixing is neglected, the SUSY two-loop contribution is given by an expression similar to Eq. (12):

$$\Delta \rho_{1,\text{gluon}}^{\text{SUSY}} = \frac{G_F \alpha_s}{4\sqrt{2} \pi^3} \left[-\sin^2 \theta_{\tilde{t}} \cos^2 \theta_{\tilde{t}} F_1(m_{\tilde{t}_1}^2, m_{\tilde{t}_2}^2) + \cos^2 \theta_{\tilde{t}} F_1(m_{\tilde{t}_1}^2, m_{\tilde{b}_L}^2) + \sin^2 \theta_{\tilde{t}} F_1(m_{\tilde{t}_2}^2, m_{\tilde{b}_L}^2) \right].$$

$$(22)$$

The two-loop gluonic SUSY contribution to $\Delta \rho$ is shown in Fig. 7 as a function of the common scalar mass $m_{\tilde{q}}$ for the two scenarios discussed previously: $\theta_{\tilde{t}} = 0$ and $\theta_{\tilde{t}} \simeq -\pi/4$. As can be seen, the two-loop contribution is of the order of 10%–15% of the one-loop result. Contrary to the SM case (and to many QCD corrections to electroweak processes in the SM; see Ref. [32] for a review) where the two-loop correction screens the one-loop contribution, $\Delta \rho_{1,gluon}^{SUSY}$ has the same sign as $\Delta \rho_0^{SUSY}$. For instance, in the case of degenerate scalar top quarks with masses $m_{\tilde{t}} \gg m_{\tilde{b}}$, the result is the same as the QCD correction to the (t,b) contribution in the SM, but with opposite sign; see Sec. IV C below. The glu-

onic correction to the contribution of scalar quarks to the ρ parameter will therefore enhance the sensitivity in the search of the virtual effects of scalar quarks in high-precision electroweak measurements. The dependence of the two-loop gluonic contribution on the top-squark mixing angle $\theta_{\tilde{t}}$ exhibits the same behavior as the one-loop correction: $\Delta \rho_{1,\text{gluon}}^{\text{SUSY}}$ is nearly constant for all possible values of $\theta_{\tilde{t}}$; only in the region of maximal mixing does it decrease rapidly.

B. Gluino exchange

Like for the gluon-exchange contribution we have also derived a complete analytic result for the gluino-exchange contribution. The complete result is, however, very lengthy and we therefore present here explicit expressions only for the limiting cases of light and heavy gluino mass, and for the case of no squark mixing. The complete expression is available in FORTRAN and MATHEMATICA format from the authors.

In order to make our expressions as compact as possible, we use $s_{\tilde{t}} \equiv \sin\theta_{\tilde{t}}$ and $c_{\tilde{t}} \equiv \cos\theta_{\tilde{t}}$ as abbreviations and introduce the following notation:

$$d_{xy} = (m_x^2 - m_y^2),$$

where

$$m_1 = m_{\tilde{t}_1}, m_2 = m_{\tilde{t}_2}, m_L = m_{\tilde{b}_L}, m_g = m_{\tilde{g}}.$$

The gluino contribution for vanishing gluino mass is given by

$$\begin{split} \Delta\rho_{1,\text{glinno}}^{\text{SUSY}} &|_{m_{\tilde{s}}^{==0}^{==0}^{=}=-\frac{\alpha_{s}}{\pi} \frac{C_{F}N_{C}G_{F}}{16\sqrt{2}\pi^{2}} \bigg[\operatorname{Li}_{2} \bigg(1-\frac{m_{t}^{2}}{m_{\tilde{b}_{L}}^{2}}\bigg) \frac{d_{L1}^{2}d_{L2}^{2}m_{t}^{2}}{d_{L1}^{2}d_{L2}m_{t}^{2}} \{d_{L2}^{2}(m_{\tilde{b}_{L}}^{4}-m_{\tilde{t}_{1}}^{4}+2m_{\tilde{b}_{L}}^{2}m_{t}^{2}) \\ &-2s_{t}^{2}m_{\tilde{b}_{L}}^{2}d_{12}[(m_{\tilde{b}_{L}}^{2}+m_{t}^{2})(m_{\tilde{b}_{L}}^{2}+m_{t}^{2}-m_{\tilde{t}_{1}}^{2})-m_{t}^{4}+m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{1}}^{2}] \} \\ &+\operatorname{Li}_{2} \bigg(1-\frac{m_{t}^{2}}{m_{\tilde{t}_{1}}^{2}}\bigg) \frac{1}{d_{L1}^{2}d_{12}m_{t}^{2}} (-d_{12}[2m_{\tilde{t}_{1}}^{6}(m_{\tilde{b}_{L}}^{2}+m_{t}^{2}-m_{\tilde{t}_{1}}^{2}]+2m_{\tilde{b}_{L}}^{2}m_{t}^{2}(m_{\tilde{b}_{L}}^{2}m_{t}^{2}-m_{\tilde{t}_{1}}^{4}+m_{t}^{4}) \\ &-m_{t}^{4}(m_{\tilde{t}_{1}}^{4}+3m_{\tilde{b}_{L}}^{4})]+s_{t}^{2} \big\{m_{\tilde{t}_{1}}^{4}(m_{\tilde{b}_{L}}^{4}-m_{\tilde{t}_{1}}^{4})d_{12}+2m_{t}^{2}m_{\tilde{t}_{1}}^{2}[m_{\tilde{b}_{L}}^{2}(m_{\tilde{b}_{L}}^{2}-m_{\tilde{t}_{1}}^{2}+3m_{\tilde{t}_{2}}^{2}) \\ &-2m_{\tilde{t}_{2}}^{2}(m_{\tilde{t}_{1}}^{4}+m_{\tilde{b}_{L}}^{4})+m_{\tilde{t}_{1}}^{6}]+m_{t}^{4}(3m_{\tilde{b}_{L}}^{4}+m_{\tilde{t}_{1}}^{4})d_{12}+2m_{t}^{2}m_{\tilde{t}_{1}}^{2}[m_{\tilde{b}_{L}}^{2}(m_{\tilde{b}_{L}}^{2}-m_{\tilde{t}_{1}}^{2}+3m_{\tilde{t}_{2}}^{2}) \\ &-2m_{\tilde{t}_{2}}^{2}(m_{\tilde{t}_{1}}^{4}+m_{\tilde{b}_{L}}^{4})+m_{\tilde{t}_{1}}^{6}]+m_{t}^{4}(3m_{\tilde{b}_{L}}^{4}+m_{\tilde{t}_{1}}^{2})d_{12}+2m_{t}^{2}(d_{L1}^{2}+2m_{t}^{2}m_{\tilde{t}_{2}}^{2}) \\ &-2m_{\tilde{t}_{2}}^{2}(m_{\tilde{t}_{1}}^{2}+m_{\tilde{b}_{L}}^{2})+m_{\tilde{t}_{1}}^{6}]+m_{t}^{4}(3m_{\tilde{b}_{L}}^{4}+m_{\tilde{t}_{1}}^{2})d_{12}+2m_{t}^{6}(d_{L1}^{2}+m_{\tilde{b}_{L}}^{2}d_{12})\}+2s_{t}^{4}m_{t}^{2}[d_{L1}^{2}(m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}-m_{t}^{4})]) \\ &+\operatorname{Li}_{2}\bigg(1-\frac{m_{t}^{2}}{m_{\tilde{t}_{2}}^{2}}\bigg)\frac{1}{d_{L2}^{2}d_{12}m_{t}^{2}}(m_{\tilde{t}_{2}}^{2}d_{12}+s_{\tilde{t}}^{2}(m_{\tilde{t}_{2}}^{2}(m_{\tilde{b}_{L}}^{2}-m_{\tilde{t}_{2}}^{2})d_{21}) \\ &+2m_{t}^{2}m_{t}^{2}m_{t}^{2}m_{t}^{2}\bigg)d_{12}+2m_{t}^{6}(-d_{L2}^{2}+m_{\tilde{b}_{L}}^{2}d_{12})\}-2s_{t}^{4}m_{t}^{2}[d_{L2}^{2}(m_{\tilde{t}_{1}}^{2}m_{t}^{2}-m_{t}^{4})]) \\ &+\frac{\ln^{2}(m_{t}^{2}m_{t}^{2})}{d_{L}^{2}d_{L}^{2}}\bigg]d_{L2}^{2}(2m_{t}^{2}m_{t}^{2}+2m_{t}^{2}m_{t}^{2}(3m_{t}^{4}+m_{t}^{4})+2m_{t}^{2}m_{t}^{2}m_{t$$

$$+2m_{t}^{2}(m_{\tilde{t}_{1}}^{2}-3m_{\tilde{b}_{L}}^{2})+m_{t}^{4}(3m_{\tilde{b}_{L}}^{2}-m_{\tilde{t}_{1}}^{2})] s_{\tilde{t}_{1}}^{2}-5m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2})$$

$$+m_{t}^{4}[6m_{\tilde{b}_{L}}^{2}(m_{\tilde{b}_{L}}^{2}-m_{\tilde{t}_{1}}^{2})+m_{t}^{2}(3m_{\tilde{b}_{L}}^{2}-m_{\tilde{t}_{2}}^{2})]]$$

$$-sw_{t}^{4}[d_{L1}d_{L2}m_{t}^{2}[10m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}-3m_{t}^{2}(m_{\tilde{t}_{1}}^{2}+m_{\tilde{t}_{2}}^{2})]]$$

$$+2s_{t}^{4}m_{t}^{2}d_{L1}(m_{\tilde{t}_{1}}^{2}-3m_{\tilde{t}_{2}}^{2})] +\frac{d_{2}^{2}\ln(|d_{2}|)}{2m_{\tilde{t}_{2}}^{2}m_{t}^{2}}m_{t}^{2}d_{L2}d$$

The result for $m_{\tilde{g}}=0$ is compared to the complete result of the gluino contribution for $m_{\tilde{g}}=10, 200, 500$ GeV in Figs. 8, 9. In Fig. 8 the results for the no-mixing scenario are displayed, while Fig. 9 shows the maximal mixing case. As expected, the curves for $m_{\tilde{g}}=0$ and $m_{\tilde{g}}=10$ GeV are very close, while the curves for large gluino masses significantly deviate from the $m_{\tilde{g}}=0$ case. For the no-mixing scenario the light gluino expression of Eq. (23) reproduces the exact result within 5×10^{-5} for $m_{\tilde{g}} < 90, 130, 350$ GeV in the cases of $m_{\tilde{q}}=100, 250, 500$ GeV, respectively. In the maximal mixing scenario the correction is much smaller for a light gluino than in the no-mixing case; the light gluino expression reproduces the exact result within 5×10^{-5} for $m_{\tilde{g}} < 20, 300, 400$ GeV in the cases of $m_{\tilde{q}}=100, 250, 500$ GeV and maximal mixing.

As second limiting case we give a series expansion in powers of the inverse gluino mass up to $\mathcal{O}(1/m_{\tilde{g}}^3)$; note that, due to the term linear in $m_{\tilde{g}}$ in Eq. (18), the expansion actually starts at $\mathcal{O}(1/m_{\tilde{g}})$:

$$\begin{split} \Delta \rho_{1,\text{gluino}}^{\text{SUSY}} &= \frac{\alpha_s}{\pi} \frac{C_F N_C G_F}{16\sqrt{2}\pi^2} \bigg\{ -2 \frac{m_t}{m_{\tilde{s}}} \frac{s_{\tilde{t}} c_{\tilde{t}} (1-2s_{\tilde{t}}^2)}{d_{L1} d_{L2} d_{12}} [d_{L1} d_{L2} d_{12} (m_{\tilde{t}_1}^2 c_{\tilde{t}}^2 - m_{\tilde{t}_2}^2 s_{\tilde{t}}^2) - m_{\tilde{b}_L}^4 d_{12}^2 \ln m_{\tilde{b}_L}^2 \\ &+ m_{\tilde{t}_1}^2 d_{L2} \ln m_{\tilde{t}_1}^2 [m_{\tilde{b}_L}^2 m_{\tilde{t}_1}^2 - 2c_{\tilde{t}}^2 m_{\tilde{t}_2}^2 m_{\tilde{b}_L}^2 + (1-2s_{\tilde{t}}^2) m_{\tilde{t}_1}^2 m_{\tilde{t}_2}^2] \\ &+ m_{\tilde{t}_2}^2 d_{L1} \ln m_{\tilde{t}_2}^2 [m_{\tilde{b}_L}^2 (m_{\tilde{t}_2}^2 - 2s_{\tilde{t}}^2 m_{\tilde{t}_1}^2) - (1-2s_{\tilde{t}}^2) m_{\tilde{t}_1}^2 m_{\tilde{t}_2}^2]] \end{split}$$

$$\begin{split} &+ \frac{1}{m_s^2} \frac{1}{3d_{L1}d_{L2}d_{12}} \Big[2d_{L1}d_{L2}d_{12}d_{12}^2 - s_i^2 (d_{12}^2 c_i^2 + d_{1L}^2 - d_{2L}^2) \\ &+ 3m_i^2 \Big[-m_{i_1}^2 (1 + 2s_i^2) + 2m_{k_L}^2 - 4m_{i_2}^2 s_i^2 + 3s_i^4 (m_{i_1}^2 + m_{i_2}^2) \Big] \\ &- 6m_{k_L}^4 d_{12}m_i^2 \ln m_{i_L}^2 (d_{12} - s_i^2 d_{12}) \\ &+ 6m_{i_1}^2 d_{12}m_i^2 c_i^2 \ln m_{i_1}^2 (d_{12} (2m_{k_L}^2 - m_{i_1}^2) + 6s_i^2 d_{L1}m_{i_2}^2) \Big] \\ &+ 6m_{i_1}^2 d_{L2}m_i^2 c_i^2 \ln m_{i_2}^2 (m_{i_2}^2 - 4m_{k_2}^2 m_{i_1}^2 - 2m_{k_1}^2 m_{i_2}^2 + 5m_{i_1}^2 m_{i_2}^2 + 6s_i^2 d_{L2}m_{i_1}^2) \\ &+ 6m_{i_1}^2 d_{L2} d_{12}m_i^2 n_{i_1}^2 m_{i_2}^2 - 4m_{k_2}^2 m_{i_1}^2 - 2m_{i_1}^2 m_{i_1}^2 + 5m_{i_1}^2 m_{i_2}^2 + 6s_i^2 d_{L2}m_{i_1}^2) \\ &+ 3d_{L1} d_{L2} d_{12}m_i^2 n_{i_1}^2 m_{i_1}^2 m_{k_2}^2 \ln m_{i_1}^2 - 2m_{i_1}^2 - s_i^2 (5m_{i_1}^2 + 3m_{i_2}^2) \\ &+ 4s_i^4 (m_{i_1}^2 + m_{i_2}^2) \Big] - 6m_{k_2}^2 d_{12}m_i^2 \ln m_{k_2}^2 \ln m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_1}^2 d_{L1} \\ &+ 4s_i^2 (m_{i_1}^2 + m_{i_2}^2) \Big] - 6m_{k_2}^2 d_{12}m_i^2 m_{k_2}^2 (m_{k_2}^2 d_{12} + 4s_{i_1}^2 m_{i_1}^2 d_{L1}) \\ &+ 6d_{L1}m_{i_1}^2 m_{i_1}^2 c_{i_1}^2 \ln m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 d_{L1} \\ &+ 6m_{i_1}^2 d_{12} d_{12} d_{12} d_{12} m_{k_2}^2 m_{i_1}^2 m_{i_2}^2 + 2m_{i_1}^2 d_{k_2}^2 m_{i_1}^2 m_{i_2}^2 - 20m_{i_1}^4 s_{i_2}^2 - 16m_{i_1}^2 m_{i_2}^2 s_{i_1}^2 + 4m_{i_2}^4 s_{i_1}^2 \\ &+ 6m_{i_1}^2 m_{i_2}^2 m_{i_2}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 + 2m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_1}^2 m_{i_2}^2 m_{i_1}^2 m_{i_$$

$$+8m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}s_{\tilde{t}}^{2}+8m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{2}}^{2}s_{\tilde{t}}^{4}-8m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}s_{\tilde{t}}^{4})$$

$$-12d_{L1}m_{\tilde{t}_{2}}^{2}m_{t}^{2}\ln m_{\tilde{t}_{2}}^{2}\ln(m_{t}^{2}/m_{\tilde{g}}^{2})(2m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{2}-5m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}+3m_{\tilde{t}_{2}}^{4})$$

$$-4m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{2}s_{\tilde{t}}^{2}-4m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{2}}^{2}s_{\tilde{t}}^{2}+8m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}s_{\tilde{t}}^{2}+8m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{2}s_{\tilde{t}}^{4}-8m_{\tilde{t}_{1}}^{2}m_{\tilde{t}_{2}}^{2}s_{\tilde{t}}^{4})]\bigg\} + \mathcal{O}\bigg(\frac{1}{m_{\tilde{g}}^{4}}\bigg).$$
(24)

Figure 10 shows the quality of the heavy gluino expansion up to $\mathcal{O}(1/m_{\tilde{g}}^3)$ in the two cases of minimal and maximal mixing for $m_{\tilde{q}} = 100$ GeV. The expansion of Eq. (24) reproduces the exact results within at most 30% (which corresponds to a maximum deviation of about 5×10^{-5} in $\Delta \rho$) for $m_{\tilde{g}} > 200$ GeV in the no-mixing case and for $m_{\tilde{g}} > 340$ GeV in the maximal mixing scenario. We have also verified that higher orders in the expansion improve significantly the convergence of the series, but we have not included unnecessary long expressions. As can be expected, when the value of $m_{\tilde{q}}$ is increased, the quality of the heavy gluino approximation deteriorates. At the same time, however, the gluino correction becomes smaller and can mostly be neglected; it never exceeds 1.5×10^{-4} and 1×10^{-4} for $m_{\tilde{q}} > 200$ GeV in the cases of minimal and maximal mixing, respectively (see Figs. 8 and 9). We conclude that in the region of the parameter space where the gluino contribution is relevant, and the gluino is not too light (say, $m_{\tilde{g}} > 300$), Eq. (24) approximates the full expression sufficiently well.

As mentioned above, for most of the parameter space the mixing in the top-squark sector is either zero or nearly maximal. As a third limiting case we give $\Delta \rho_{1,\text{gluino}}^{\text{SUSY}}$ for arbitrary $m_{\tilde{g}}$, but with zero top-squark mixing. The result in this limiting case has already been displayed in Fig. 8 and Fig. 10 (solid curve):

$$\begin{split} \Delta\rho_{1,\text{glund}}^{\text{SUSY}}|_{M_{t}^{t,k}=0} &= \frac{\alpha_{s}}{\pi} \frac{C_{r}N_{c}G_{F}}{16\sqrt{2}\pi^{2}} \left\{ 13m_{\tilde{s}}^{2} - 4m_{\tilde{b}_{L}}^{2} - \frac{9}{2}m_{\tilde{t}_{1}}^{2} - \frac{1}{2}m_{\tilde{t}_{2}}^{2} - \frac{(m_{\tilde{t}_{1}}^{2} - 5m_{\tilde{b}_{L}}^{2})m_{t}^{2}}{d_{L1}} \right. \\ &+ \frac{1}{2} \sum_{l=1,2} (m_{\tilde{s}}^{2} - m_{\tilde{t}_{1}}^{2} + m_{t}^{2}) B_{0}^{6n}(m_{\tilde{t}_{1}}^{2}, m_{\tilde{s}}, m_{\tilde{t}_{1}}) \\ &- \frac{m_{\tilde{s}}^{2} - m_{\tilde{t}_{1}}^{2} + m_{t}^{2}}{d_{L1}^{2}} B_{0}^{6n}(m_{\tilde{t}_{1}}^{2}, m_{\tilde{s}}, m_{t}) \left(3m_{\tilde{b}_{L}}^{4} - 4m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{2} + m_{\tilde{t}_{1}}^{4} - 2m_{\tilde{b}_{L}}^{4} \ln \frac{m_{\tilde{b}_{L}}^{2}}{m_{\tilde{t}_{1}}^{2}} \right) - \frac{d_{gL}}{d_{L1}^{2}} B_{0}^{6n}(m_{\tilde{b}_{L}}^{2}, m_{\tilde{s}}^{2}, 0) \\ &\times \left(m_{\tilde{b}_{L}}^{4} - 4m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{2} + 3m_{\tilde{t}_{1}}^{4} - 2m_{\tilde{t}_{1}}^{4} \ln \frac{m_{\tilde{t}_{L}}^{2}}{m_{\tilde{b}_{L}}^{2}} \right) - \frac{d_{gL}}{d_{1L}^{2}} m_{t}^{2} L^{1} \left(1 - \frac{m_{\tilde{s}}^{2}}{m_{\tilde{b}_{L}}^{2}} \right) \left[d_{gL}d_{1L}(m_{\tilde{b}_{L}}^{2} - 2m_{\tilde{s}}^{2} + m_{\tilde{t}_{1}}^{2}) \right] \\ &+ 2m_{\tilde{t}_{1}}^{2} m_{t}^{2} (2m_{\tilde{t}_{1}}^{2} - m_{\tilde{b}_{L}}^{2} - m_{\tilde{s}}^{2}) \left[2d_{\tilde{s}_{L}}^{2} L^{1} \left(1 - \frac{m_{\tilde{s}}^{2}}{m_{\tilde{b}_{L}}^{2}} \right) \left[lm_{\tilde{s}_{L}}^{2} L^{1} \left(m_{\tilde{s}_{L}}^{2} - m_{\tilde{s}_{L}}^{2} + m_{\tilde{s}_{1}}^{2} \right) \right] \\ &+ 2m_{\tilde{t}_{1}}^{2} m_{t}^{2} (2m_{\tilde{t}_{1}}^{2} - m_{\tilde{s}_{L}}^{2}) + \left(3m_{\tilde{s}}^{2} + \sum_{i=1,2} \frac{m_{\tilde{s}}^{2} - 2m_{\tilde{s}}^{4}m_{\tilde{t}_{i}}^{2} + m_{\tilde{s}}^{2}m_{\tilde{t}_{i}}^{4} m_{\tilde{t}}^{2} - m_{\tilde{s}}^{2}m_{\tilde{t}_{i}}^{2} \right) \right] \ln m_{\tilde{s}}^{2} \\ &- \frac{2}{d_{\tilde{t}_{1}}^{2}} \left[4L_{1} \left[m_{\tilde{s}}^{2} (3m_{\tilde{b}_{L}}^{2} + m_{\tilde{t}_{1}}^{2} \right] - 2m_{\tilde{b}_{L}}^{2} m_{\tilde{t}_{1}}^{2} \right] + 2m_{\tilde{b}_{L}}^{4} m_{\tilde{t}}^{2} m_{\tilde{s}}^{2} m_{\tilde{t}_{i}}^{2} \right] \ln m_{\tilde{s}}^{2} \\ &- \frac{2}{d_{\tilde{t}_{1}}^{2}} \left[4L_{1} \left[m_{\tilde{s}}^{2} (3m_{\tilde{b}_{L}}^{2} + m_{\tilde{t}_{1}}^{2} \right] + \left(3m_{\tilde{s}}^{2} + \sum_{i=1,2} \frac{m_{\tilde{s}}^{2} - 2m_{\tilde{s}}^{2} m_{\tilde{t}_{i}}^{2} m_{\tilde{t}_{i}}^{2} \right) \ln m_{\tilde{s}}^{2} \\ &- \frac{2}{d_{\tilde{t}_{1}}^{2}} \left[4L_{1} \left[m_{\tilde{s}}^{2} (3m_{\tilde{s}_{L}}^{2} + m_{\tilde{t}_{1}}^{2} \right] + \left(2m_{\tilde{s}}^{2} + m_{\tilde{t}_{1}}^{2} \right] \ln$$

(25)

$$\begin{split} &+ 2m_{\tilde{t}_{1}}^{2}m_{t}^{2}(2m_{\tilde{t}_{1}}^{2} - m_{\tilde{b}_{L}}^{2} - m_{\tilde{s}}^{2})\ln^{2}m_{\tilde{b}_{L}}^{2} - \left[\frac{m_{t}^{2}}{2} + \frac{1}{d_{L^{1}}^{2}m_{t}^{2}}\left\{m_{t}^{2}\left[m_{t}^{4}\left[m_{s}^{4}\left(3m_{\tilde{b}_{L}}^{2} - 4m_{\tilde{t}_{1}}^{2}\right) - m_{\tilde{t}_{1}}^{2}d_{L^{1}}\right] \\ &+ m_{\tilde{t}_{1}}^{4}(2m_{\tilde{s}}^{2} - m_{\tilde{b}_{L}}^{2})\right]+d_{s}^{3}(d_{L1} + m_{t}^{4}\left[m_{\tilde{b}_{L}}^{2}\left(m_{\tilde{t}_{1}}^{2} + m_{\tilde{s}_{L}}^{2}\right) - m_{\tilde{s}}^{2}d_{L1}\right] - m_{t}^{6}m_{\tilde{b}_{L}}^{2}\right]\ln m_{\tilde{t}_{1}}^{2}\ln m_{\tilde{s}}^{2} \\ &- \frac{1}{2d_{L^{1}}^{2}m_{t}^{2}}\left\{d_{s}^{2}(d_{s}^{1} + d_{s}^{L})d_{LL} \\ &+ 2m_{t}^{2}\left[m_{s}^{4}(-3m_{\tilde{b}_{L}}^{2} + 4m_{\tilde{t}_{1}}^{2}) + m_{\tilde{t}_{1}}^{4}(m_{\tilde{b}_{L}}^{2} - 2m_{\tilde{s}}^{2})\right] + m_{t}^{4}\left[(m_{\tilde{b}_{L}}^{2} + m_{\tilde{s}}^{2})^{2} \\ &- (m_{\tilde{t}_{1}}^{2} + m_{\tilde{s}}^{2})^{2} - 4m_{\tilde{b}_{L}}^{4} + 2m_{t}^{6}m_{\tilde{b}_{L}}^{2}\right]\ln m_{\tilde{s}}^{2}\ln m_{\tilde{b}_{L}}^{2} + (5d_{s}^{2}_{1} + d_{s}^{2} - 4d_{s}^{1}d_{L1} + d_{L}^{2} - 2m_{\tilde{t}_{1}}^{2}m_{\tilde{t}}^{2}\right) \\ &\times (\ln m_{\tilde{s}}^{2}\ln m_{t}^{2})/(2m_{t}^{2}) + \left\{d_{\tilde{s}L}^{2}(d_{s}^{1} + d_{s}^{L})d_{L1} - 2m_{t}^{2}(m_{\tilde{s}}^{2}m_{\tilde{b}_{L}}^{2})(3m_{\tilde{s}}^{2} - 2m_{\tilde{b}_{L}}^{2}) - 2m_{\tilde{s}}^{4}m_{\tilde{t}_{1}}^{2} + m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{4}\right] \\ &+ m_{t}^{4}d_{L1}(2m_{\tilde{s}}^{2} + m_{\tilde{t}_{1}}^{2} + m_{\tilde{b}_{L}}^{2}) + 2m_{t}^{6}m_{\tilde{b}_{L}}^{2}\right]\frac{\ln m_{\tilde{b}_{L}}^{2}\ln m_{t}^{2}}{2m_{t}^{2}d_{L_{1}}^{2}} \\ &+ \left[\frac{m_{t}^{2}}{2} - m_{\tilde{t}_{1}}^{2} - m_{\tilde{t}_{1}}^{2} - \frac{1}{d_{L}^{2}m_{t}^{2}}\left\{d_{s}^{3}d_{L1} + m_{t}^{2}d_{s}\right]\left[2d_{L}^{2}L + m_{\tilde{b}_{L}}^{2}m_{\tilde{t}_{1}}^{2} + m_{\tilde{s}}^{2}(2m_{\tilde{t}_{1}}^{2} - 3m_{\tilde{b}_{L}}^{2})\right] + m_{t}^{4}(m_{\tilde{s}}^{2} + m_{\tilde{b}_{L}^{2}})d_{L} \\ &+ m_{t}^{6}m_{\tilde{b}_{L}}^{2}\right\left]\ln m_{t}^{2}\ln m_{\tilde{t}_{1}}^{2} - \frac{\lambda^{2}(m_{\tilde{s}}^{2}m_{t}^{2} - m_{\tilde{t}_{L}}^{2})}{2m_{t}^{2}m_{\tilde{b}_{L}}^{2}}\left\{m_{t}^{2}\left[m_{t}^{2}\left(m_{\tilde{t}_{1}^{2}\right) + m_{t}^{4}\left(m_{\tilde{s}}^{2} + m_{\tilde{s}_{L}}^{2}\right)\right] \\ &+ m_{t}^{6}m_{\tilde{b}_{L}}^{2}\right\right]\ln m_{t}^{2}\ln m_{\tilde{t}_{1}}^{2} + \frac{\lambda^{2}(m_{\tilde{s}}^{2}m_{t}^{2} - m_{\tilde{t}_{L}}^{2})}{2m_{t}^{2}m_{\tilde{s}_{L}}^{2}}\left\{m_{t}^{2}\left[m_{t}^{2}\left(m_{t$$

Here we have used $\lambda(x,y,z) \equiv \sqrt{(z-x-y)^2 - 4xy}$ and the function $\Phi(x,y,z)$ is defined according to the sign of $\lambda(x,y,z)^2$. For $\lambda(x,y,z)^2 \ge 0$,

while for $\lambda(x,y,z)^2 \leq 0$,

Г

$$\Phi(x,y,z) = \frac{z}{\lambda} \left\{ 2\ln\left(\frac{z+x-y-\lambda}{2z}\right) \ln\left(\frac{z+y-x-\lambda}{2z}\right) -\ln\frac{x}{z}\ln\frac{y}{z} - 2\operatorname{Li}_2\left(\frac{z+x-y-\lambda}{2z}\right) -2\operatorname{Li}_2\left(\frac{z+y-x-\lambda}{2z}\right) + \frac{\pi^2}{3} \right\}, \quad (26)$$

$$\Phi(x,y,z) = \frac{2z}{\sqrt{-\lambda^2}} \left\{ \operatorname{Cl}_2 \left[2 \operatorname{arccos} \left(\frac{x+y-z}{2\sqrt{xy}} \right) \right] + \operatorname{Cl}_2 \left[2 \operatorname{arccos} \left(\frac{x-y+z}{2\sqrt{xz}} \right) \right] + \operatorname{Cl}_2 \left[2 \operatorname{arccos} \left(\frac{z-x+y}{2\sqrt{yz}} \right) \right] \right\},$$
(27)

where $Cl_2(x) = Im Li_2(e^{ix})$ is the Clausen function; limiting expressions and additional details on this function can be found in Ref. [28].

C. Supersymmetric limit

The sign of the gluonic two-loop contributions is, as discussed above, always the same as the sign of the one-loop contribution, contrary to the case of the two-loop contributions in the SM. In the limit of vanishing gluino mass, $m_{\tilde{t}_1} = m_{\tilde{t}_2} = m_t$, $m_{\tilde{b}_L} = m_b = 0$ (supersymmetric limit), the gluon-exchange contribution of the scalar quarks reads

$$\Delta \rho_{1, \text{gluon}}^{\text{SUSY}} = \frac{\alpha_s G_F m_t^2}{\sqrt{2} \pi^3} \frac{3 + \pi^2}{12} = \Delta \rho_0^{\text{SM}} \frac{2}{3} \frac{\alpha_s}{\pi} \left(1 + \frac{\pi^2}{3}\right),$$
(28)

which exactly cancels the quark loop contribution [12]. The gluino-exchange contribution in this limit is given by

$$\Delta \rho_{1,\,\text{gluino}}^{\text{SUSY}} = -\Delta \rho_0^{\text{SM}} \frac{8}{3} \frac{\alpha_s}{\pi},\tag{29}$$

which numerically cancels almost completely the contribution of Eq. (28).

D. Corrections to the squark masses

The analytical formulas for $\Delta \rho$ given in the previous sections are exclusively expressed in terms of the physical squark masses. The formulas therefore allow a general analysis since they do not rely on any specific model assumption for the mass values. For our numerical analysis, however, since the physical values of the squark masses are unknown, we had to calculate the masses from the (unphysical) soft-SUSY-breaking mass parameters. We have concentrated on the MSSM scenario with soft breaking terms obeying the SU(2) relation $M_{\tilde{t}_L} = M_{\tilde{b}_L}$. The \tilde{t} and \tilde{b} masses are obtained by diagonalizing the tree-level mass matrices. Using Eqs. (1)–(3), the masses $m_{\tilde{t}_1}, m_{\tilde{t}_2}$, and $m_{\tilde{b}_L} = m_{\tilde{b}_1}^{-5}$ as well as the mixing angle $\theta_{\tilde{t}}$, can be expressed in terms of the three parameters $M_{\tilde{t}_L}, M_{\tilde{t}_R}$, and M_t^{LR} . This yields the tree-level mass relation

$$m_{\tilde{b}_{1}}^{2} = \cos^{2}\theta_{\tilde{t}}m_{\tilde{t}_{1}}^{2} + \sin^{2}\theta_{\tilde{t}}m_{\tilde{t}_{2}}^{2} - m_{t}^{2} - \cos^{2}\beta M_{W}^{2}.$$
 (30)

When higher-order corrections are included, the quantities $M_{\tilde{t}_L}$ and $M_{\tilde{b}_L}$ are renormalized by different counterterms once the on-shell renormalization for the \tilde{t} and \tilde{b} squarks is performed. Requiring the SU(2) relation

$$M_{\tilde{t}_L}^2 + \delta M_{\tilde{t}_L}^2 = M_{\tilde{b}_L}^2 + \delta M_{\tilde{b}_L}^2$$
(31)

for the bare parameters at the one-loop level, one obtains $M_{\tilde{t}_L} \neq M_{\tilde{b}_L}$ for the renormalized parameters (see also the discussion in Ref. [33]). The difference $\delta M_{\tilde{t}_L}^2 - \delta M_{\tilde{b}_L}^2 = \Delta m_{\tilde{b}_1}^2$, with

$$\delta M_{\tilde{t}_{L}}^{2} = \cos^{2}\theta_{\tilde{t}} \delta m_{\tilde{t}_{1}}^{2} + \sin^{2}\theta_{\tilde{t}} \delta m_{\tilde{t}_{2}}^{2} + (m_{\tilde{t}_{2}}^{2} - m_{\tilde{t}_{1}}^{2}) \sin 2\theta_{\tilde{t}} \delta\theta_{\tilde{t}} - 2m_{t} \delta m_{t}, \quad (32)$$

$$\delta M_{\tilde{b}_L}^2 = \delta m_{\tilde{b}_1}^2, \tag{33}$$

constitutes a finite $\mathcal{O}(\alpha_s)$ contribution to the \tilde{b}_1 mass compared to its tree-level value. The mass shift $\Delta m_{\tilde{b}_1}^2$ can also be obtained by replacing the tree-level quantities in Eq. (30) by their renormalized values and the corresponding counterterms. We have explicitly checked that the quantity $\Delta m_{\tilde{h}_{\star}}^2$ is indeed finite. Note that the squark mass and mixing angle counterterms in Eqs. (32) and (33) also receive contributions from the pure scalar diagrams of the type of Fig. 6c which in the two-loop results given above canceled between the counterterm graphs and the two-loop diagrams. For the top-quark mass counterterm in Eq. (33) also the graph with gluon exchange enters, which was absent in the results given above. Because of the latter contribution, the $\mathcal{O}(\alpha_s)$ correction to Eq. (30) is different in the dimensional regularization and the dimensional reduction scheme, while for all results given above the two schemes yield identical results. In our numerical analysis in this section we use the result for the top-quark mass counterterm in dimensional reduction.

For the two-loop contribution to the ρ parameter, the difference generated by using the tree-level mass relations instead of the one-loop corrected ones is of three-loop order and therefore not relevant at the order of perturbation under consideration. However, if the one-loop contribution to $\Delta \rho$ is evaluated by calculating the squark masses from the soft breaking parameters as described above, the $\mathcal{O}(\alpha_s)$ correction to the \tilde{b}_1 mass should be taken into account. This gives rise to an extra contribution compared to the results discussed in Sec. II.

The tree-level relation $M_{\tilde{t}_L} = M_{\tilde{t}_R}$, which has been widely used in our numerical examples, can in principle be maintained also for the renormalized parameters at the one-loop level with on-shell \tilde{t}_1, \tilde{t}_2 mass renormalization. Alternatively, in the spirit of the discussion given above, one may assume that the symmetry is extended to the bare parameters:

$$M_{\tilde{t}_L}^2 + \delta M_{\tilde{t}_L}^2 = M_{\tilde{t}_R}^2 + \delta M_{\tilde{t}_R}^2.$$
(34)

Accordingly, the squark masses and the mixing angle are in this scenario given in terms of the two parameters $m_{\tilde{q}}$ and M_t^{LR} , and there exist two relations between the squark masses and the top-squark mixing angle at the tree level,

$$m_{\tilde{t}_2}^2 = m_{\tilde{t}_1}^2 + \frac{1}{\sin^2 \theta_{\tilde{t}} - \cos^2 \theta_{\tilde{t}}} \cos 2\beta M_Z^2 \left(\frac{1}{2} - \frac{4}{3} s_W^2\right),$$
(35)

⁵Since we set $m_b = 0$, thus neglecting mixing in the \tilde{b} sector, we have $m_{\tilde{b}_1} = m_{\tilde{b}_1}$, and $m_{\tilde{b}_2}$ decouples from the ρ parameter.

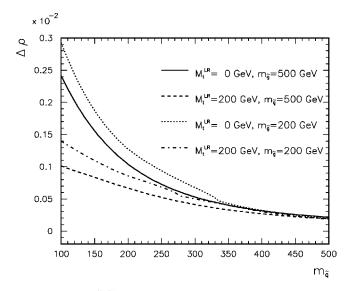

FIG. 11. $\Delta \rho_0^{\text{SUSY}}$ calculated with one-loop corrected squark masses as a function of $m_{\tilde{q}}$ for $\theta_{\tilde{t}}=0$ and $\theta_{\tilde{t}}\sim -\pi/4$ (tan β =1.6, $M_t^{LR}=0$ or 200 GeV) and two values of $m_{\tilde{g}}$.

$$m_{\tilde{b}_{1}}^{2} = m_{\tilde{t}_{1}}^{2} - m_{t}^{2} + \frac{1}{\sin^{2}\theta_{\tilde{t}} - \cos^{2}\theta_{\tilde{t}}} \times \cos^{2}\beta M_{Z}^{2} \left[c_{W}^{2} - \sin^{2}\theta_{\tilde{t}} \left(\frac{3}{2} - \frac{2}{3}s_{W}^{2} \right) \right].$$
(36)

At $\mathcal{O}(\alpha_s)$, the right-hand sides of Eqs. (35) and (36) receive the extra contributions $\Delta m_{\tilde{t}_2}^2$ and $\Delta m_{\tilde{b}_1}^2$, respectively, where

$$\Delta m_{\tilde{t}_2}^2 = \delta m_{\tilde{t}_1}^2 - \delta m_{\tilde{t}_2}^2 + \frac{\sin 2\theta_{\tilde{t}} \delta\theta_{\tilde{t}}}{(\sin^2\theta_{\tilde{t}} - \cos^2\theta_{\tilde{t}})^2} \times \cos 2\beta M_Z^2 \bigg(-1 + \frac{8}{3} s_W^2 \bigg), \qquad (37)$$

$$\Delta m_{\tilde{b}_{1}}^{2} = \delta m_{\tilde{t}_{1}}^{2} - \delta m_{\tilde{b}_{1}}^{2} - 2m_{t}\delta m_{t}$$

$$+ \frac{\sin 2\theta_{\tilde{t}}\delta\theta_{\tilde{t}}}{2(\sin^{2}\theta_{\tilde{t}} - \cos^{2}\theta_{\tilde{t}})^{2}} \cos 2\beta M_{Z}^{2} \left(-1 + \frac{8}{3}s_{W}^{2}\right).$$
(38)

These relations have been used in the numerical evaluation displayed in Fig. 11. The difference to the case with $M_{\tilde{t}_L} = M_{\tilde{t}_n}$ at the renormalized level is only marginal.

The effect of the $\mathcal{O}(\alpha_s)$ corrections to the mass relations on $\Delta \rho_0$ is shown in Fig. 11, where the one-loop correction to the ρ parameter is expressed in terms of $m_{\tilde{q}}$, but with the corrections, Eqs. (37) and (38), to the mass relations taken into account. The results are shown for the no-mixing and the maximal mixing case and for two values of the gluino mass, $m_{\tilde{g}} = 200$ and 500 GeV. Compared to Fig. 2, where the tree-level mass relations have been used as input, the contribution of the (\tilde{t}, \tilde{b}) doublet to the ρ parameter is reduced for the parameter space chosen in the figure.

The inclusion of the one-loop corrections to the squark mass relations does not always lead to a decrease of $\Delta \rho_0$, but can also give rise to a significant enhancement. This is quantitatively shown in Table II for the same scenario as in Table I, i.e., for the maximal mixing case with $\tan\beta = 1$. The shift for the bottom-squark mass in this case follows from Eqs. (32) and (33) in the limit $\theta_{\tilde{t}} = -\pi/4$ with $\delta \theta_{\tilde{t}} = 0$. The numerical results are very similar to the case with $\tan\beta = 1.6$. The value chosen for the gluino mass is $m_{\tilde{g}} = 500$ GeV, and for completeness also the full two-loop contribution $\Delta \rho_1^{SUSY}$ is given. One can see that for large values of the nondiagonal element in the \tilde{t} mass matrix, $\Delta \rho_0$ can become larger compared to the entries in Table I, thus significantly increasing $\Delta \rho$ at the two-loop level in a range where the one-loop contribution is already quite large.

In the situation where the relation $M_{\tilde{t}_L} = M_{\tilde{t}_R}$ is relaxed and the squark masses and the mixing angle are derived from

TABLE II. $\Delta \rho_0^{\text{SUSY}}$ in units of 10^{-3} for the same scenario as in Table I, i.e., with $\tan\beta = 1$, for several values of $m_{\tilde{q}}$ and M_t^{LR} . The $\mathcal{O}(\alpha_s)$ correction to the tree-level mass relation has been taken into account for $m_{\tilde{g}} = 500$ GeV. The two-loop contributions $\Delta \rho_{1,\text{gluon}}^{\text{SUSY}}$ and $\Delta \rho_{1,\text{gluino}}^{\text{SUSY}}$ are also given (in units of 10^{-4} , $m_{\tilde{g}} = 500$ GeV).

$m_{\tilde{q}}$ (GeV)	M_t^{LR} (GeV)	$\Delta ho_0^{ m SUSY} imes 10^{-3}$	$\Delta ho_{ m 1,gluon}^{ m SUSY} imes 10^{-4}$	$\Delta ho_{1,\mathrm{gluino}}^{\mathrm{SUSY}} \! imes 10^{-4}$

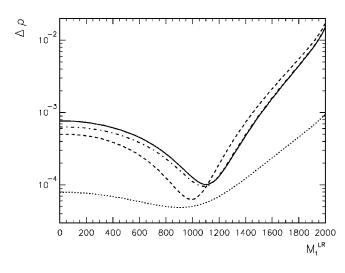

FIG. 12. $\Delta \rho_0^{\text{SUSY}}$ as a function of M_t^{LR} for $\tan \beta = 1.6$ and for $M_{\tilde{t}_L}/M_{\tilde{t}_R} = 1000/300$ (dotted line; the lines for tree-level and one-loop parameters are not distinguishable) and 300/1000 (solid line for tree-level parameters; for the one-loop parameters, dash-dotted line for $m_{\tilde{g}} = 200$ GeV and dashed line for $m_{\tilde{g}} = 500$ GeV.

 $M_{\tilde{t}_L}, M_{\tilde{t}_R}$, and M_t^{LR} , Fig. 12 shows $\Delta \rho_0^{\text{SUSY}}$ for the two choices $M_{\tilde{t}_L}/M_{\tilde{t}_R} = 300/1000$ and 1000/300 as a function of M_t^{LR} . For the $M_{\tilde{t}_L}/M_{\tilde{t}_R} = 300/1000$ case the solid line corresponds to the use of the tree-level masses, while the others reflect the use of the one-loop correction $\Delta m_{\tilde{b}_1}^2$ to the tree-level masses following from Eqs. (32) and (33) for two gluino masses $m_{\tilde{g}} = 200, 500$ GeV. For the $M_{\tilde{t}_L}/M_{\tilde{t}_R} = 1000/300$ case the result is given by the dotted line. It is insensitive to the one-loop correction to the squark masses; we therefore show only a single curve. For the $M_{\tilde{t}_L}/M_{\tilde{t}_R} = 300/1000$ case, $\Delta \rho_0$ is decreased for small values of M_t^{LR} , $\Delta \rho_0$ can become huge in this scenario, exceeding the level of experimental observability. The bounds on the breaking parameters obtained from experiment will therefore crucially depend on the proper inclusion of the two-loop contributions.

V. CONCLUSIONS

We have calculated the $\mathcal{O}(\alpha_s)$ correction to the squark loop contributions to the ρ parameter in the MSSM. The result can be divided into a gluonic contribution, which is typically of $\mathcal{O}(10\%)$ and dominates in most of the parameter space, and a gluino contribution, which goes to zero for large gluino masses as a consequence of decoupling. Only for gluino, top-squark and bottom-squark masses close to their lower experimental bounds does the gluino contribution become comparable to the gluon correction. In this case, the gluon and gluino contributions add up to $\sim 30\%$ of the oneloop value for maximal mixing. In general the sum of gluonic and gluino corrections enters with the same sign as the one-loop contribution. It thus leads to an enhancement of the one-loop contribution (expressed in terms of the physical squark masses) and an increased sensitivity in the search for scalar quarks through their virtual effects in high-precision electroweak observables. This is in contrast to what happens in the SM, where the two-loop QCD corrections enter with opposite sign and screen the one-loop result.

While the gluonic contribution can be presented in a very compact form, the complete analytical result for the gluino correction is very lengthy. We have therefore not written it out explicitly but have given expressions for three limiting cases, namely, the result for zero squark mixing, for vanishing gluino mass, and an expansion for a heavy gluino mass. These limiting cases approximate the exact result sufficiently well for practical purposes. The results have been given in terms of the on-shell squark masses and are therefore independent of any specific scenario assumed for the mass values. For different scenarios we have analyzed the extra con tributions caused by the $\mathcal{O}(\alpha_s)$ correction to the tree-level mass relations.
