(Received 9 February 2007; published 18 April 2007)

We report improved measurements of B decays with an η meson in the final state using 492 fb^{-1} of data collected by the Belle detector at the KEKB e^+e^- collider. We observe the decays $B^\pm \rightarrow \eta\pi^\pm$ and $B^\pm \rightarrow \eta K^\pm$ and measure the branching fractions $\mathcal{B}(B^\pm \rightarrow \eta\pi^\pm) = (4.2 \pm 0.4(\text{stat}) \pm 0.2(\text{sys})) \times 10^{-6}$ and $\mathcal{B}(B^\pm \rightarrow \eta K^\pm) = (1.9 \pm 0.3(\text{stat})_{-0.1}^{+0.2}(\text{sys})) \times 10^{-6}$. The corresponding CP -violating asymmetries are measured to be $-0.23 \pm 0.09(\text{stat}) \pm 0.02(\text{sys})$ for $\eta\pi^\pm$ and $-0.39 \pm 0.16(\text{stat}) \pm 0.03(\text{sys})$ for ηK^\pm . We also search for $B^0 \rightarrow \eta K^0$ decays and set an upper limit of 1.9×10^{-6} at the 90% confidence level.

Charmless B decays provide a rich sample to understand B decay dynamics and to search for CP violation. The decay $B \rightarrow \eta K$ proceeds through a $b \rightarrow s$ penguin process and a $b \rightarrow u$ tree transition. Interference from the two penguin processes, $b \rightarrow s\bar{s}s$ and $b \rightarrow u\bar{u}s$, and the known $\eta - \eta'$ mixing are expected to enhance the $B \rightarrow \eta' K$ branching fraction but suppress $B \rightarrow \eta K$ [1]. The situation is reversed for the ηK^* and $\eta' K^*$ modes since the η and K^* mesons are in a relative p -wave rather than an s -wave state. Experimental results [2–5] have confirmed this picture but more precise measurements of ηK and $\eta' K^*$ are needed for a quantitative understanding of the underlying dynamics. Moreover, the penguin amplitude of ηK may interfere with the $b \rightarrow u$ amplitude, resulting in a large direct CP asymmetry (A_{CP}) [6]. Theoretical expectations for contributions from other mechanisms [7–9] also suggest a large A_{CP} although the sign could be positive or negative. Our earlier measurements with limited statistics [3] indicated a large negative A_{CP} central value for ηK^\pm . The study of $B^0 \rightarrow \eta K^0$ is of particular interest because this decay is a CP eigenstate and could be used for time dependent CP measurements.

The dominant process in $B \rightarrow \eta\pi$ decays is the (external) $b \rightarrow u$ tree while a suppressed $b \rightarrow d$ penguin process may also contribute. It has been argued [7,10] that the direct CP violating asymmetry could be large in the $\eta\pi^\pm$ and $\eta'\pi^\pm$ modes, whose branching fractions are expected to be around $(2\text{--}5) \times 10^{-6}$ [9,10].

In this paper, we report improved measurements of branching fractions and partial rate asymmetries for $B \rightarrow \eta h$ decays, where h is a charged or neutral K meson or a charged π meson. The partial rate asymmetry for charged B decays is defined to be:

$$A_{CP} = \frac{N(B^- \rightarrow \eta h^-) - N(B^+ \rightarrow \eta h^+)}{N(B^- \rightarrow \eta h^-) + N(B^+ \rightarrow \eta h^+)}, \quad (1)$$

where $N(B^- \rightarrow \eta h^-)$ is the yield obtained for the $B^- \rightarrow \eta h^-$ decay and $N(B^+ \rightarrow \eta h^+)$ denotes that of the charge-conjugate mode. The data sample consists of 535×10^6 $B\bar{B}$ pairs (492 fb^{-1}) collected with the Belle detector at the KEKB e^+e^- asymmetric-energy (3.5 on 8 GeV) collider [11] operating at the $\Upsilon(4S)$ resonance. Throughout this paper, the inclusion of the charge-conjugate decay mode is implied unless otherwise stated.

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Čerenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter (ECL) comprised of CsI(Tl) crystals located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux-return located outside the coil is instrumented to detect K_L^0 mesons and to identify muons (KLM). The detector is described in detail elsewhere [12]. In August 2003, the three-layer SVD was replaced by a four-layer device with greater radiation tolerance [13]. The data sample used in this analysis consists of 140 fb^{-1} of data with the old SVD (set I) and 352 fb^{-1} with the new one (set II).

The event selection and B candidate reconstruction are similar to those documented in our previous publication [3]. Two η decay channels are considered in this analysis: $\eta \rightarrow \gamma\gamma$ ($\eta_{\gamma\gamma}$) and $\eta \rightarrow \pi^+\pi^-\pi^0$ ($\eta_{3\pi}$). We require photons from the η and π^0 candidates to have laboratory energies (E_γ) above 50 MeV. In the $\eta_{\gamma\gamma}$ reconstruction, the photon energy asymmetry, $\frac{|E_{\gamma 1} - E_{\gamma 2}|}{E_{\gamma 1} + E_{\gamma 2}}$, is required to be

less than 0.9 to reduce the large combinatorial background from soft photons. Neither photon from $\eta_{\gamma\gamma}$ is allowed to pair with any other photon having $E_\gamma > 100$ MeV to form a π^0 candidate. Candidate π^0 mesons are selected by requiring the two-photon invariant mass to be in a mass window between 115 and 152 MeV/ c^2 . The momentum vector of each photon is then readjusted to constrain the mass of the photon pair to the nominal π^0 mass.

Candidate $\eta_{3\pi}$ mesons are reconstructed by combining π^0 candidates with at least 250 MeV/ c laboratory momentum with a pair of oppositely charged tracks that originate from the interaction point (IP). We impose the following requirements on the invariant mass of the η candidates in both data sets: $516 \text{ MeV}/c^2 < M_{\gamma\gamma} < 569 \text{ MeV}/c^2$ for $\eta_{\gamma\gamma}$ and $539 \text{ MeV}/c^2 < M_{3\pi} < 556 \text{ MeV}/c^2$ for $\eta_{3\pi}$. After the selection of each candidate, the η mass constraint is implemented by readjusting the momentum vectors of the daughter particles.

Charged tracks are required to come from the IP. Charged kaons and pions, which are combined with η mesons to form B candidates, are identified using a $K(\pi)$ likelihood $L_K(L_\pi)$ obtained by combining information from the CDC (dE/dx), the TOF and the ACC. Discrimination between kaons and pions is achieved through a requirement on the likelihood ratio $L_K/(L_\pi + L_K)$. Charged tracks with likelihood ratios greater than 0.6 are regarded as kaons, and less than 0.4 as pions. Charged tracks that are positively identified as electrons or muons are rejected. The K/π identification efficiencies (PID) and misidentification rates are determined from a sample of $D^{*+} \rightarrow D^0 \pi^+$, $D^0 \rightarrow K^- \pi^+$ decays with kaons and pions in the same kinematic region of two-body B decays. The kaon (pion) identification efficiency is 83% (90%) and 6.4% (11.7%) of pions (kaons) will be misidentified as kaons (pions). The systematic error of the K/π selection is about 1.3% for pions and 1.5% for kaons, respectively.

K_S^0 candidates are reconstructed from pairs of oppositely charged tracks with an invariant mass ($M_{\pi\pi}$) between 480 and 516 MeV/ c^2 . Each candidate must have a displaced vertex with a flight direction consistent with that of a K_S^0 -meson originating from the IP.

Candidate B mesons are identified using the beam-energy constrained mass, $M_{bc} = \sqrt{E_{\text{beam}}^2 - P_B^2}$, and the energy difference, $\Delta E = E_B - E_{\text{beam}}$, where E_{beam} is the run-dependent beam energy in the Y(4S) rest frame determined from $B \rightarrow D^{(*)}\pi$ events, and P_B and E_B are the momentum and energy, respectively, of the B candidate in the Y(4S) rest frame. The resolutions in M_{bc} and ΔE are about 3 MeV/ c^2 and 20–30 MeV, respectively. Events with $M_{bc} > 5.2 \text{ GeV}/c^2$ and $|\Delta E| < 0.3 \text{ GeV}$ are selected for the analysis.

The dominant background comes from the $e^+e^- \rightarrow q\bar{q}$ continuum, where $q = u, d, s$ or c . To distinguish signal from the jetlike continuum background, event shape vari-

ables and B flavor tagging information are employed. We combine the correlated shape variables into a Fisher discriminant [14] and then compute a likelihood that is the product of probabilities based on this discriminant and $\cos\theta_B$, where θ_B is the angle between the B flight direction and the beam direction in the Y(4S) rest frame. A likelihood ratio, $\mathcal{R} = \mathcal{L}_s/(\mathcal{L}_s + \mathcal{L}_{q\bar{q}})$, is formed from signal (\mathcal{L}_s) and background ($\mathcal{L}_{q\bar{q}}$) likelihoods, obtained from Monte Carlo simulation (MC) and from data with $M_{bc} < 5.26 \text{ GeV}/c^2$, respectively. Signal MC events for the charged B modes are generated with the PHOTOS [15] simulation package to take into account final state radiation. Additional background discrimination is provided by B flavor tagging. Events that contain a lepton are more likely to be $B\bar{B}$ events so a looser \mathcal{R} requirement is applied. The standard Belle B tagging package [16] provides two outputs: a discrete variable (q) indicating the tagged side flavor and a dilution factor (r) ranging from zero for no flavor information to unity for unambiguous flavor assignment. Since the charged B modes are flavor specific, the wrong flavor tagged events are likely to be background and a tight \mathcal{R} requirement can be applied. We divide the data into six subsamples based on the q and r information for the charged modes and the r value only for the neutral mode. Continuum suppression is achieved by applying a mode-dependent requirement on \mathcal{R} for events in each subsample that maximizes $N_s^{\text{exp}}/\sqrt{N_s^{\text{exp}} + N_{q\bar{q}}^{\text{exp}}}$, where N_s^{exp} is the number of signal events expected from MC and $N_{q\bar{q}}^{\text{exp}}$ denotes the number of background events estimated from data. After applying the \mathcal{R} requirements, we select one candidate per event based on the best \mathcal{R} . The fraction of events with multiple candidates are $\sim 1\%$ for the $\gamma\gamma$ mode and $\sim 2\text{--}3\%$ for the $\pi^+\pi^-\pi^0$ mode.

Using a large MC sample, all other backgrounds are found to be negligible except for $\eta K^+(\eta\pi^+)$ reflecting into the $\eta\pi^+(\eta K^+)$ sample, due to $K^+ \rightarrow \pi^+(\pi^+ \rightarrow K^+)$ misidentification, and the feed-down from charmless B decays, predominantly $B \rightarrow \eta K^*(892)$ and $B \rightarrow \eta\rho(770)$. We include the reflection and charmless components in the fit used to extract the signal.

The signal yields and partial rate asymmetries are obtained using an extended unbinned maximum-likelihood (ML) fit with input variables M_{bc} and ΔE . The likelihood is defined as

$$\mathcal{L} = e^{-\sum_i N_i} \times \prod_i \left(\sum_j N_j \mathcal{P}_j^i \right) \quad \text{and} \quad (2)$$

$$\mathcal{P}_j^i = \frac{1}{2} [1 - q^i \cdot A_{CPj}] P_j(M_{bc}^i, \Delta E^i), \quad (3)$$

where i is the identifier of the i th event and N_j is the number of events for the category j , which corresponds to either signal, $q\bar{q}$ continuum, the reflection due to $K-\pi$ misidentification, or background from other charmless B

TABLE I. Detection efficiency (ϵ) including subdecay branching fraction [19], yield, significance, measured branching fraction (\mathcal{B}), the 90% C.L. upper limit (UL) and A_{CP} for the $B \rightarrow \eta h$ decays. The first errors in columns 3, 5 and 7 are statistical and the second errors are systematic.

Mode	ϵ (%)	Yield	Significance	$\mathcal{B}(10^{-6})$	UL(10^{-6})	A_{CP}
$B^\pm \rightarrow \eta \pi^\pm$			14.7	$4.2 \pm 0.4 \pm 0.2$		$-0.23 \pm 0.09 \pm 0.02$
$\eta_{\gamma\gamma} \pi^\pm$	8.3	183 ± 20	11.9	$4.1^{+0.5}_{-0.4} \pm 0.2$		$-0.11 \pm 0.11 \pm 0.01$
$\eta_{3\pi} \pi^\pm$	3.1	73^{+13}_{-12}	8.7	$4.4^{+0.8}_{-0.7} \pm 0.3$		$-0.52 \pm 0.16 \pm 0.02$
$B^\pm \rightarrow \eta K^\pm$			8.1	$1.9 \pm 0.3^{+0.2}_{-0.1}$		$-0.39 \pm 0.16 \pm 0.03$
$\eta_{\gamma\gamma} K^\pm$	7.3	72^{+14}_{-13}	6.4	$1.9^{+0.4}_{-0.3} \pm 0.1$		$-0.30 \pm 0.19 \pm 0.02$
$\eta_{3\pi} K^\pm$	2.7	29 ± 8	4.8	$2.0^{+0.6}_{-0.4} \pm 0.2$		$-0.55^{+0.27+0.05}_{-0.28-0.04}$
$B^0 \rightarrow \eta K^0$			2.9	$1.1 \pm 0.4 \pm 0.1$	< 1.9	
$\eta_{\gamma\gamma} K^0$	2.6	16 ± 8	2.6	$1.1^{+0.6}_{-0.5} \pm 0.1$	< 2.2	
$\eta_{3\pi} K^0$	1.0	$4.6^{+4.6}_{-3.7}$	1.2	$0.9^{+0.9}_{-0.7} \pm 0.1$	< 2.4	

decays. $P_j(M_{bc}, \Delta E)$ is the two-dimensional probability density function (PDF) in M_{bc} and ΔE , and q indicates the B meson flavor, B^+ ($q = +1$) or B^- ($q = -1$). For the neutral B mode, \mathcal{P}_j^i in Eq. (2) is simply $P_j(M_{bc}^i, \Delta E^i)$ and there is no component from charged particle misidentification.

In Ref. [17] we reported that in both data sets the PID efficiency is slightly different for positively and negatively charged particles. Therefore, the raw asymmetry defined in Eq. (1) must be corrected. This efficiency difference results in an A_{CP} bias of -0.005 ($+0.005$) for $\eta\pi$ (ηK). The bias is subtracted from the raw asymmetry.

The PDFs for the signal, the reflection background and the charmless feed-down are modeled with two-dimensional M_{bc} - ΔE smooth functions obtained using large MC samples. The signal peak positions and resolutions in M_{bc} and ΔE are adjusted according to the data-MC differences using large control samples of $B \rightarrow D\pi$ and $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$ decays. The continuum background in ΔE is described by a first- or second-order polynomial, while the M_{bc} distribution is parametrized by an ARGUS function, $f(x) = x\sqrt{1-x^2} \exp[-\xi(1-x^2)]$, where x is M_{bc}/E_{beam} [18]. The continuum PDF is thus formed by the product of an ARGUS function and a polynomial, where ξ and the coefficients of the polynomial are free parameters.

The partial rate asymmetries of the charmless B backgrounds are fixed to zero in the fit while the A_{CP} and normalizations of the reflection components are fixed to expectations based on the $B^+ \rightarrow \eta K^+$ and $B^+ \rightarrow \eta \pi^+$ partial rate asymmetries and branching fractions, as well as $K^+ \leftrightarrow \pi^+$ fake rates. The reflection yield and A_{CP} are first input with the assumed values and are then recalculated according to our measured results.

Table I shows the measured branching fractions for each decay mode as well as other quantities associated with the measurements. The efficiency for each mode is determined using MC simulation and corrected for the data-MC discrepancy obtained from the control sample studies. In

addition to the particle identification performance discrepancy, our MC slightly overestimates the efficiency for detecting low momentum π^0 s, which results in a 3.1% correction for the $\eta_{3\pi}$ mode. The combined branching fraction for the two data sets is computed as the sum of the yield divided by its efficiency in each set divided by the number of B mesons, while the partial rate asymmetry for the charged mode is computed using the sum of the yield

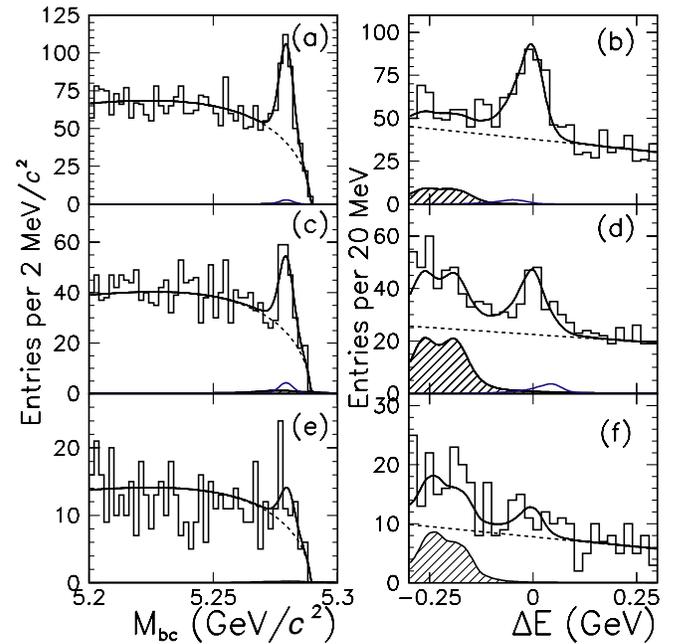

FIG. 1 (color online). M_{bc} and ΔE projections for (a),(b) $B^\pm \rightarrow \eta \pi^\pm$, (c),(d) $B^\pm \rightarrow \eta K^\pm$, and (e),(f) $B^0 \rightarrow \eta K^0$ decays with the $\eta_{\gamma\gamma}$ and $\eta_{3\pi}$ modes combined. Open histograms are data, solid curves are the fit functions, dashed lines show the continuum contributions and shaded histograms are the feed-down component from charmless B decays. The small contributions around $M_{bc} = 5.28 \text{ GeV}/c^2$ and $\Delta E = \pm 0.05 \text{ GeV}$ in (a)–(d) are the reflection backgrounds from $B^\pm \rightarrow \eta K^\pm$ and $B^\pm \rightarrow \eta \pi^\pm$.

divided by its efficiency in each set in Eq. (1). The combined branching fraction and partial rate asymmetry of the two η decay modes are obtained from the weighted average assuming the errors are Gaussian. The number of B^+B^- and $B^0\bar{B}^0$ pairs are assumed to be equal. Figure 1 shows the M_{bc} and ΔE projections after requiring events to satisfy $-0.10 \text{ GeV} < \Delta E < 0.08 \text{ GeV}$ and $M_{bc} > 5.27 \text{ GeV}/c^2$, respectively.

Systematic uncertainties due to the signal PDFs used in the fit are estimated by performing the fit after varying the signal peak positions and resolutions by 1 standard deviation (σ). We also examine the changes in yield and A_{CP} when the requirement of no asymmetry for the charmless background is removed. In $B^\pm \rightarrow \eta\pi^\pm$, the reflection yields are estimated to be 9.4 ± 3.1 events for the $\eta_{\gamma\gamma}$ mode and 3.6 ± 1.9 for $\eta_{3\pi}$ while in $B^\pm \rightarrow \eta K^\pm$, the reflection yields are 13.9 ± 3.7 for $\eta_{\gamma\gamma}$ and 4.6 ± 2.1 for $\eta_{3\pi}$. The reflection yields and their A_{CP} values are varied by 1 standard deviation in the fit to obtain the corresponding systematic uncertainties. The quadratic sum of the deviations from the central value gives the systematic uncertainty in the fit. A statistical significance is calculated as $\mathcal{S} = \sqrt{-2 \ln \mathcal{L}_0 - (-2 \ln \mathcal{L}_{\max})}$, where $-2 \ln \mathcal{L}_0$ is for zero signal yield and $-2 \ln \mathcal{L}_{\max}$ is for the best-fit value. The final significance including systematic uncertainty is

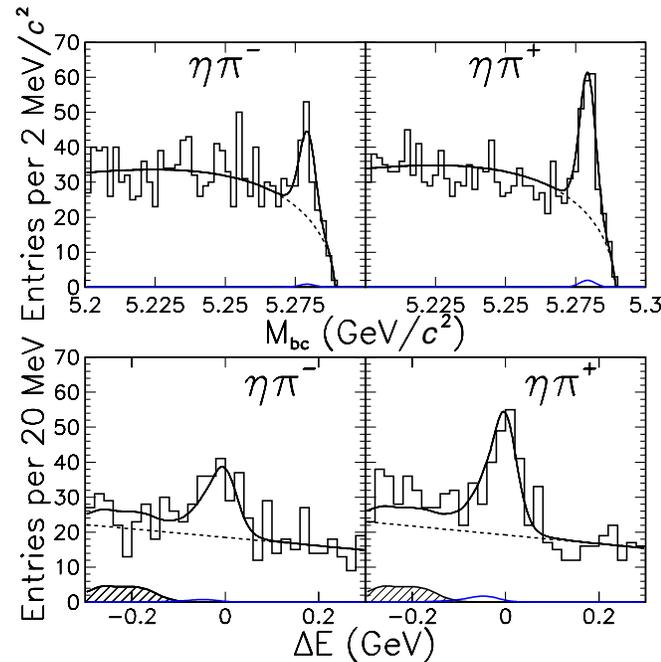

FIG. 2 (color online). M_{bc} and ΔE projections for (left) $B^- \rightarrow \eta\pi^-$ and (right) $B^+ \rightarrow \eta\pi^+$ with the $\eta_{\gamma\gamma}$ and $\eta_{3\pi}$ modes combined. Open histograms are data, solid curves are the fit functions, dashed lines show the continuum contributions and shaded histograms are the contributions from charmless B decays. The small contributions near $M_{bc} = 5.28 \text{ GeV}/c^2$ and $\Delta E = -0.05 \text{ GeV}$ are the backgrounds from misidentified $B^\pm \rightarrow \eta K^\pm$ (reflections).

taken as $\mathcal{S} = \mathcal{S}_o - \sqrt{\sum(\mathcal{S}_o - \mathcal{S}_i)^2}$, where \mathcal{S}_o is the statistical significance for the fit and \mathcal{S}_i is the significance obtained for each systematic check with the value smaller than \mathcal{S}_o .

The possible detector bias due to the tracking acceptance for $A_{CP}(B^\pm \rightarrow \eta\pi^\pm)$ and $A_{CP}(B^\pm \rightarrow \eta K^\pm)$ is evaluated using the A_{CP} value of the continuum component. No obvious bias is observed and we use the statistical error of the $\eta_{\gamma\gamma}$ and $\eta_{3\pi}$ modes combined as the systematic error. The bias error of 0.01 is added in quadrature with the fit systematic error to give the final systematic uncertainty in Table I. Figures 2 and 3 show the M_{bc} and ΔE projections for the B^+ and B^- samples. In both the $\eta\pi^\pm$ and ηK^\pm modes, we observe larger B^+ signals.

The systematic error of the efficiency arises from the \mathcal{R} requirement, tracking efficiency, particle identification, K_S^0 reconstruction, π^0 and $\eta_{\gamma\gamma}$ reconstruction, and $\eta_{\gamma\gamma}$ and $\eta_{3\pi}$ branching fractions. The performance of the \mathcal{R} requirement is studied by checking the data-MC efficiency ratio using the $B^+ \rightarrow \bar{D}^0\pi^+$ control sample. The systematic errors on the charged track reconstruction are estimated to be 1% per track using partially reconstructed D^* events. The π^0 and $\eta_{\gamma\gamma}$ reconstruction efficiency is verified by comparing the π^0 decay angular distribution with the MC prediction, and by measuring the ratio of the branching fractions for the two D decay channels $\bar{D}^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$. The K_S^0 reconstruction is

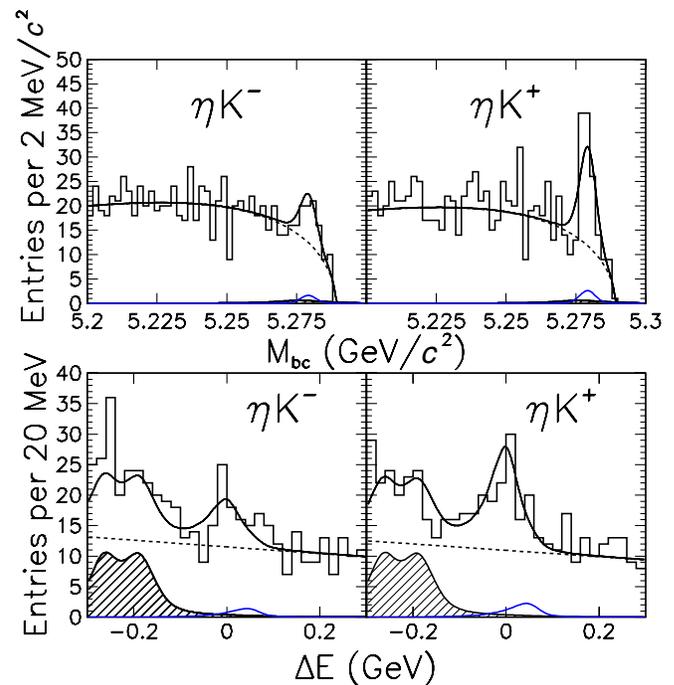

FIG. 3 (color online). M_{bc} and ΔE projections for (left) $B^- \rightarrow \eta K^-$ and (right) $B^+ \rightarrow \eta K^+$ with the $\eta_{\gamma\gamma}$ and $\eta_{3\pi}$ modes combined. All symbols are the same as in Fig. 2. The small contributions near $M_{bc} = 5.28 \text{ GeV}/c^2$ and $\Delta E = 0.05 \text{ GeV}$ are the backgrounds from misidentified $B^\pm \rightarrow \eta\pi^\pm$ (reflections).

TABLE II. The systematic uncertainties for the $B \rightarrow \eta h$ branching fractions, given in %. The fit systematic errors include the uncertainties due to the signal PDFs, the yields of the reflection backgrounds and the partial rate asymmetries of the charmless B and reflection backgrounds.

verified by comparing the ratio of $D^+ \rightarrow K_S^0\pi^+$ and $D^+ \rightarrow K^- \pi^+ \pi^+$ yields. The uncertainties in the $\eta_{\gamma\gamma}$ and $\eta_{3\pi}$ branching fractions are taken from Ref. [19]. Table II summarizes the systematic uncertainties, including the error on the number of $B\bar{B}$ events. The systematic error that arises from how well PHOTOS describes final state radiation is found to be negligible [20]. The final systematic error for the combined branching fraction is obtained by assuming that the systematic errors for the subdecay modes are 100% correlated.

We observe an excess of $B^0 \rightarrow \eta K^0$ events but the significance is slightly less than 3. Therefore, an upper limit on the branching fraction at 90% confidence level is provided. To calculate this limit, we find the yield for which 90% of the area of the likelihood function lies at lower values. We divide the yield by the reconstruction efficiency reduced by 1σ of its uncertainty, which is the quadratic sum of the errors given in rows 2–8 of Table II. The result is then inflated by the 1σ uncertainty due to the parameters fixed in the fit (first row of Table II) to obtain the upper limit including all systematic uncertainties.

In summary, we have observed $B^\pm \rightarrow \eta\pi^\pm$ and $B^\pm \rightarrow \eta K^\pm$ decays; their branching fractions are measured to be $(4.2 \pm 0.4 \pm 0.2) \times 10^{-6}$ and $(1.9 \pm 0.3_{-0.1}^{+0.2}) \times 10^{-6}$, respectively. These results with improved precisions are consistent with our previously published measurements [3] and the earlier BABAR results [4]. The CP -violating asymmetries are measured to be $A_{CP}(B^\pm \rightarrow \eta\pi^\pm) =$

$-0.23 \pm 0.09 \pm 0.02$ and $A_{CP}(B^\pm \rightarrow \eta K^\pm) = -0.39 \pm 0.16 \pm 0.03$, which are 2.5σ and 2.4σ away from zero, respectively. It is interesting to note that the A_{CP} values for these two modes obtained by the BABAR Collaboration are also negative, slightly more than 1σ away from zero for each mode. Larger data samples are needed to verify these large CP asymmetries. Finally, we find a hint of an ηK^0 signal with $\mathcal{B}(B^0 \rightarrow \eta K^0) = (1.1 \pm 0.4 \pm 0.1) \times 10^{-6}$. Since the measurement is not significant, we provide an upper limit at the 90% confidence level of 1.9×10^{-6} . A similar hint was also observed by the BABAR Collaboration with a central value of $(1.5 \pm 0.7 \pm 0.1) \times 10^{-6}$. The combined average, $(1.2 \pm 0.4) \times 10^{-6}$, shows 3.4σ evidence for the CP eigenstate decay $B^0 \rightarrow \eta K^0$. Our measurements supersede the Belle previously published results.

We thank the KEKB group for the excellent operation of the accelerator, the KEK Cryogenics group for the efficient operation of the solenoid, and the KEK computer group and the NII for valuable computing and Super-SINET network support. We acknowledge support from MEXT and JSPS (Japan); ARC and DEST (Australia); NSFC (Contract No. 10175071, China); DST (India); the BK21 program of MOEHRD and the CHEP SRC program of KOSEF (Korea); KBN (Contract No. 2P03B 01324, Poland); MIST (Russia); MESS (Slovenia); NSC and MOE (Taiwan); and DOE (U.S.).
