

Critical gravity on AdS₂ spacetimesYun Soo Myung,^{1,*} Yong-Wan Kim,^{1,†} and Young-Jai Park^{2,‡}¹*Institute of Basic Science and School of Computer Aided Science, Inje University, Gimhae 621-749, Korea*²*Department of Physics and Department of Service Systems Management and Engineering, Sogang University, Seoul 121-742, Korea*

(Received 6 June 2011; published 28 September 2011)

We study the critical gravity in two-dimensional anti-de Sitter (AdS₂) spacetimes, which was obtained from the cosmological topologically massive gravity (TMG_Λ) in three dimensions by using the Kaluza-Klein dimensional reduction. We perform the perturbation analysis around AdS₂, which may correspond to the near-horizon geometry of the extremal Banados, Teitelboim, and Zanelli (BTZ) black hole obtained from the TMG_Λ with identification upon uplifting three dimensions. A massive propagating scalar mode δF satisfies the second-order differential equation away from the critical point of $K = l$, whose solution is given by the Bessel functions. On the other hand, δF satisfies the fourth-order equation at the critical point. We exactly solve the fourth-order equation, and compare it with the log gravity in two dimensions. Consequently, the critical gravity in two dimensions could not be described by a massless scalar δF_{ml} and its logarithmic partner $\delta F_{\text{log}}^{\text{4th}}$.

I. INTRODUCTION

The gravitational Chern-Simons (gCS) terms in three-dimensional (3D) Einstein gravity produce a physically propagating massive graviton [1]. This topologically massive gravity with a negative cosmological constant $\Lambda = -1/l^2$ (TMG_Λ [2]) gives us the three-dimensional anti-de Sitter (AdS₃) solution [3]. For the positive Newton's constant G_3 , a massive graviton mode carries ghost (negative energy) on the AdS₃. In this sense, the AdS₃ is not a stable vacuum. The opposite case of $G_3 < 0$ may cure the problem, but it may induce a negative Deser-Tekin mass for the Banados, Teitelboim, and Zanelli (BTZ) black hole [4]. It seems that there is one way of avoiding negative energy by choosing the chiral (critical) point of $K = l$ with the gCS coupling constant K . At this point, a massive graviton becomes a massless left-moving graviton, which carries no energy. It may be considered as gauge-artefact. However, the critical point has raised many questions on physical degrees of freedom [5–12].

The gCS terms are not invariant under coordinate transformations though they are conformally invariant [13,14]. It is known that the 3D Einstein gravity is locally trivial and, thus, does not have any physically propagating modes. However, all solutions to the Einstein gravity are also solutions to the TMG_Λ. Therefore, it would be better to seek another method to find a propagating massive mode in the TMG_Λ since it is likely a candidate for a nontrivial 3D gravity, in addition to the new massive gravity [15]. To this end, one may introduce a conformal transformation and then the Kaluza-Klein reduction can be used to obtain an effective two-dimensional action (2DTMG_Λ), which

becomes a gauge and coordinate invariant action. Sahoo and Sen [16,17] have used the 2DTMG_Λ to derive the entropy of the extremal BTZ black hole [18] by using the entropy function formalism (AdS₂ attractor equation). When using the Achúcarro-Ortiz type of dimensional reduction, it turned out that there is no propagating massive mode on the AdS₂ background [19].

In this work, we will focus on the chiral point of $K = l$, where a massive graviton ψ_{mn}^M turned out to be a left-moving graviton ψ_{mn}^L [3,20]. Grumiller and Johansson have introduced a new field $\psi_{mn}^{\text{new}} = \partial_{l/K} \psi_{mn}^M|_{K=l}$ as a logarithmic partner of ψ_{mn}^L [6] based on the logarithmic conformal field theory with $c_L = 0$ [21–24]. However, it was reported that ψ_{mn}^{new} might not be a physical field at the chiral point, since it belongs to the nonunitary theory. This is so because $(\psi_{mn}^L, \psi_{mn}^{\text{new}})$ become a pair of dipole ghost fields [25]. At this stage, we would like to mention that the linearized higher dimensional critical gravities were recently investigated in the AdS spacetimes [26], but the nonunitary issue of the log gravity is not still resolved, indicating that the log gravity suffers from the ghost problem.

A few years ago, we carried out perturbation analysis of the 2DTMG_Λ around the AdS₂ background [27]. We showed that the dual scalar δF of the Maxwell field is a gauge-invariant massive mode propagating in the AdS₂ background. Recently, we have studied the critical gravity arisen from the new massive gravity by investigating quasinormal modes to check the stability of the BTZ black hole [28].

Hence it is interesting to study the critical gravity arisen from the 2DTMG_Λ, which shows a fourth-order differential equation on the AdS₂ background.

The organization of our work is as follows. In Sec. II, we study the 2DTMG_Λ, which was obtained from the TMG_Λ by using the Kaluza-Klein dimensional reduction. In

Sec. III, we briefly review the perturbation analysis around AdS_2 , which may correspond to the near-horizon geometry of the extremal BTZ black hole obtained from the TMG_Λ with identification upon uplifting three dimensions. We find an explicit solution of a physically propagating scalar mode δF satisfying the second-order differential equation away from the critical point of $K = l$. At the critical point, in Sec. IV, the 2DTMG_Λ turns out to be the 2D dilaton gravity including the Maxwell field obtained from 3D Einstein gravity, which shows that there are no propagating modes. We exactly solve the fourth-order equation at the critical point, and compare it with the log-gravity ansatz in two dimensions. Discussion is given in Sec. V.

II. 2DTMG_Λ

We start with the action for the TMG_Λ given by [1]

$$I_{\text{TMG}_\Lambda} = \frac{1}{16\pi G_3} \int d^3x \sqrt{-g} \left[R_3 - 2\Lambda - \frac{K}{2} \varepsilon^{lmn} \Gamma^p{}_{lq} \left(\partial_m \Gamma^q{}_{np} + \frac{2}{3} \Gamma^q{}_{mr} \Gamma^r{}_{np} \right) \right], \quad (1)$$

where ε is the tensor defined by $\varepsilon/\sqrt{-g}$ with $\varepsilon^{012} = 1$. We choose the positive Newton's constant $G_3 > 0$ and the negative cosmological constant $\Lambda = -1/l^2$. The Latin indices of l, m, n, \dots denote three-dimensional tensors. The K term is called the gCS terms. Here we choose the minus sign in the front of K [17]. Varying this action leads to the Einstein equation

$$G_{mn} - K C_{mn} = 0, \quad (2)$$

where the Einstein tensor is given by

$$G_{mn} = R_{3mn} - \frac{R_3}{2} g_{mn} - \frac{1}{l^2} g_{mn}, \quad (3)$$

$$I_{2\text{DTMG}_\Lambda} = \frac{l}{8G_3} \int d^2x \sqrt{-g} \left(\phi R + \frac{2}{\phi} g^{\mu\nu} \nabla_\mu \phi \nabla_\nu \phi + \frac{2}{l^2} \phi^3 - \frac{1}{4} \phi F_{\mu\nu} F^{\mu\nu} \right) - \frac{Kl}{32G_3} \int d^2x (R \varepsilon^{\mu\nu} F_{\mu\nu} + \varepsilon^{\mu\nu} F_{\mu\rho} F^{\rho\sigma} F_{\sigma\nu}), \quad (8)$$

which is *our main action to study the critical gravity in two dimensions*. Here R is the 2D Ricci scalar with $R_{\mu\nu} = R g_{\mu\nu}/2$, and ϕ is a dilaton. Also, the Maxwell field is defined by $F_{\mu\nu} = 2\partial_{[\mu} A_{\nu]}$, and $\varepsilon^{\mu\nu}$ is a tensor density. The Greek indices of μ, ν, ρ, \dots represent two-dimensional tensors. Hereafter we choose $G_3 = l/8$ for simplicity. It is again noted that this action was actively used to derive the entropy of an extremal BTZ black hole by applying the entropy function approach [16,17,27]. Introducing a dual scalar F of the Maxwell field defined by [13,14]

$$F \equiv -\frac{1}{2\sqrt{-g}} \varepsilon^{\mu\nu} F_{\mu\nu}, \quad (9)$$

equations of motion for ϕ and A_μ are given, respectively, by

and the Cotton tensor is defined by

$$C_{mn} = \varepsilon_m{}^{pq} \nabla_p \left(R_{3qn} - \frac{1}{4} g_{qn} R_3 \right). \quad (4)$$

We note that the Cotton tensor C_{mn} vanishes for any solution to the 3D Einstein gravity, so all solutions of the Einstein gravity are also solutions of the TMG_Λ . Hence, the BTZ black hole with $K = 0$ [18] appears as a solution to the full Eq. (2):

$$ds_{\text{BTZ}}^2 = -N^2(r) dt^2 + \frac{dr^2}{N^2(r)} + r^2 [d\theta + N^\theta(r) dt]^2, \quad (5)$$

where the squared lapse $N^2(r)$ and the angular shift $N^\theta(r)$ take the forms

$$N^2(r) = -8G_3 m + \frac{r^2}{l^2} + \frac{16G_3^2 j^2}{r^2}, \quad N^\theta(r) = -\frac{4G_3 j}{r^2}. \quad (6)$$

Here m and j are the mass and angular momentum of the BTZ black hole, respectively.

We first make a conformal transformation and then perform Kaluza-Klein dimensional reduction by choosing the metric [13,14]

$$ds_{\text{KK}}^2 = \phi^2 [g_{\mu\nu}(x) dx^\mu dx^\nu + (d\theta + A_\mu(x) dx^\mu)^2] \quad (7)$$

because the gCS terms are invariant under the conformal transformation. Here θ is a coordinate that parametrizes an S^1 with a period $2\pi l$. Hence, its isometry is factorized as $\mathcal{G} \times U(1)$. After the “ θ ” integration, the action (1) reduces to an effective two-dimensional action called the 2DTMG_Λ as

$$R + \frac{2}{\phi^2} (\nabla\phi)^2 - \frac{4}{\phi} \nabla^2 \phi + \frac{6}{l^2} \phi^2 + \frac{1}{4} F^2 = 0, \quad (10)$$

$$\varepsilon^{\mu\nu} \partial_\nu \left[\phi F + \frac{K}{2} (R + 3F^2) \right] = 0. \quad (11)$$

The equation of motion for the metric $g_{\mu\nu}$ takes the form

$$g_{\mu\nu} \left(\nabla^2 \phi - \frac{1}{l^2} \phi^3 + \frac{1}{4} \phi F^2 - \frac{1}{\phi} (\nabla\phi)^2 \right) + \frac{2}{\phi} \nabla_\mu \phi \nabla_\nu \phi - \nabla_\mu \nabla_\nu \phi + \frac{K}{2} \left[g_{\mu\nu} \left(\nabla^2 F + F^3 + \frac{1}{2} R F \right) - \nabla_\mu \nabla_\nu F \right] = 0. \quad (12)$$

The trace part of Eq. (12)

$$\nabla^2 \phi - \frac{2}{l^2} \phi^3 + \frac{1}{2} \phi F^2 + K \left(\frac{1}{2} R F + F^3 + \frac{1}{2} \nabla^2 F \right) = 0 \quad (13)$$

is relevant to our perturbation study. On the other hand, the traceless part is given by

$$g_{\mu\nu} \left(\frac{1}{2} \nabla^2 \phi - \frac{1}{\phi} (\nabla \phi)^2 \right) + \frac{2}{\phi} \nabla_\mu \phi \nabla_\nu \phi - \nabla_\mu \nabla_\nu \phi + \frac{K}{4} g_{\mu\nu} \nabla^2 F - \frac{K}{2} \nabla_\mu \nabla_\nu F = 0 \quad (14)$$

which may provide a redundant constraint [19]. Now, we are in a position to find AdS₂ spacetimes as a vacuum solution to (10), (11), and (13). In case of a constant dilaton, from (10) and (13), we have the condition of a vacuum state

$$(3KF + 2\phi) \left(\frac{\phi^2}{l^2} - \frac{1}{4} F^2 \right) = 0, \quad (15)$$

which provides two distinct relations between ϕ and F

$$\phi_\pm = \pm \frac{l}{2} F. \quad (16)$$

Assuming the line element preserving $\mathcal{G} = SL(2, R)$ isometry

$$ds_{\text{AdS}_2}^2 = \bar{g}_{\mu\nu} dx^\mu dx^\nu = v \left(-r^2 dt^2 + \frac{dr^2}{r^2} \right), \quad (17)$$

we have the AdS₂ spacetimes, which satisfy

$$\bar{R} = -\frac{2}{v}, \quad \bar{\phi} = u, \quad \bar{F} = \frac{e}{v} (\bar{F}_{10} = e). \quad (18)$$

Here $\bar{F}_{10} = \partial_1 \bar{A}_0 - \partial_0 \bar{A}_1$ with $\bar{A}_0 = er$ and $\bar{A}_1 = 0$. This background may correspond to the near-horizon geometry of the extremal BTZ black hole (NHEB), factorized as AdS₂ \times S¹ as

$$ds_{\pm\text{NHEB}}^2 = \frac{l^2}{4} \left[-r^2 dt^2 + \frac{dr^2}{r^2} + (dz \mp r dt)^2 \right], \quad (19)$$

where $v = l^2/4$ and $z = l\theta/|e|$ with the identification of $z \sim 2\pi l n \frac{l}{|e|}$. Here n is an integer. As was pointed out in Ref. [29], the NHEB is a self-dual orbifold of AdS₃. This geometry has a null circle on its boundary, and thus, the dual conformal field theory is a discrete light cone quantized of two-dimensional conformal field theory (CFT₂). The kinematics of the discrete light cone quantized show that in a consistent quantum field theory of gravity in these backgrounds, there is no dynamics in AdS₂, which is consistent with the Kaluza-Klein reduction of the 3D Einstein gravity. However, the gCS terms in the TMG_Λ are odd under parity, and as a result, the theory shows a single massive propagating degree of freedom of a given helicity, whereas the other helicity mode remains massless. The single massive field is realized as a massive scalar $\varphi = z^{3/2} h_{zz}$ when using the Poincaré coordinates

x^\pm and z covering the AdS₃ spacetimes [5,10]. We have shown that a propagating massive mode is a dual scalar δF of the Maxwell field on a self-dual orbifold of AdS₃ (AdS₂ background) [27].

III. PERTURBATION AROUND AdS₂

We briefly review the perturbation around the AdS₂ and find the explicit form of a massive propagating mode. Let us first consider the perturbation modes of the dilaton, graviton, and dual scalar around the AdS₂ background as

$$\phi = \bar{\phi} + \varphi, \quad (20)$$

$$g_{\mu\nu} = \bar{g}_{\mu\nu} + h_{\mu\nu}, \quad h_{\mu\nu} = -h \bar{g}_{\mu\nu}, \quad (21)$$

$$F = \bar{F}(1 + \delta F), \quad \delta F = \left(h - \frac{f}{e} \right), \quad (22)$$

where the bar variables denote the AdS₂ background (17) and (18). The Maxwell field has a scalar perturbation f around the background: $F_{10} = \bar{F}_{10} + \delta F_{10}$, where $\delta F_{10} = -f$. We note that two scalars of δF and φ are gauge-invariant quantities in AdS₂ spacetimes although f is not [27]. Then, considering $\delta R(h) = \bar{\nabla}^2 h - \frac{2}{v} h$, the perturbed equations of motion to (10), (11), and (13) are given, respectively, by

$$\bar{\nabla}^2 h - \frac{2}{v} h - \frac{4}{u} \bar{\nabla}^2 \varphi + \frac{12}{l^2} u \varphi + \frac{e^2}{v^2} \delta F = 0, \quad (23)$$

$$\epsilon^{\mu\nu} \partial_\nu \left[\frac{e}{v} (\varphi + u \delta F) + \frac{K}{2} \left(\bar{\nabla}^2 h - \frac{2}{v} h + \frac{6e^2}{v^2} \delta F \right) \right] = 0, \quad (24)$$

$$\bar{\nabla}^2 \varphi - \frac{6}{l^2} u^2 \varphi + \frac{e^2}{2v^2} \varphi + \frac{ue^2}{v^2} \delta F + K \left(\frac{e}{2v} \bar{\nabla}^2 h - \frac{e}{v^2} h + \frac{e(3e^2 - v)}{v^3} \delta F + \frac{e}{2v} \bar{\nabla}^2 \delta F \right) = 0. \quad (25)$$

Solving (24) for δF and inserting it into Eq. (25) leads to

$$\left(\bar{\nabla}^2 - \frac{2}{v} \right) \left(\varphi + \frac{Ke}{2v} \delta F \right) = 0. \quad (26)$$

Also, solving (24) for $(\bar{\nabla}^2 - \frac{2}{v})h$ and then inserting it into Eq. (23) arrives at

$$\left(\bar{\nabla}^2 - \frac{2}{v} \right) \varphi - \left(\frac{ue}{2vK} + \frac{5}{4v} \right) (\varphi + u \delta F) = 0. \quad (27)$$

Making use of (26) and (27), δF and φ satisfy the coupled equation

$$\left(\bar{\nabla}^2 - \frac{2}{v} \right) \delta F - \frac{2v}{Ke} \left(\frac{ue}{2vK} + \frac{5}{4v} \right) (\varphi + u \delta F) = 0. \quad (28)$$

Acting $(\bar{\nabla}^2 - \frac{2}{v})$ on (28), and then eliminating φ again by using (26), one finds the fourth-order equation for δF as follows:

$$\left(\bar{\nabla}^2 - \frac{2}{v}\right)\left[\bar{\nabla}^2 - \left(\frac{2}{v} + m_{\pm}^2\right)\right]\delta F = 0, \quad (29)$$

for the two AdS₂ solutions of $u = \pm \ell e/2v$ in (16). Here, the mass squared m_{\pm}^2 is given by

$$m_{\pm}^2 = \frac{1}{4v}\left(\pm \frac{l}{K} - 1\right)\left(5 \pm \frac{l}{K}\right). \quad (30)$$

Here we stress that our mass squared is defined differently from Ref. [27]. For $0 \leq K \leq l$, one requires $m^2 \geq 0$, which selects $m_+^2 \equiv m^2$ (see Fig. 1). Hereafter we consider this case only. For $m^2 \neq 0$, the fourth-order Eq. (29) implies 2 s order equations: one is for a massless field

$$\left[\bar{\nabla}^2 - \frac{2}{v}\right]\delta F = 0, \quad (31)$$

while the other is for a massive scalar

$$\left[\bar{\nabla}^2 - \left(\frac{2}{v} + m^2\right)\right]\delta F = 0. \quad (32)$$

In order to solve the massive Eq. (32), we transform the AdS₂ metric as

$$ds_{\text{AdS}_2}^2 = v\left(-r^2 dt^2 + \frac{dr^2}{r^2}\right) \quad (33)$$

$$\rightarrow -\left(\frac{x^2}{v}\right)dt^2 + \left(\frac{v}{x^2}\right)dx^2 \quad (34)$$

$$\rightarrow \frac{ds^2}{v} = \left(\frac{1}{x_*^2}\right)[-dt^2 + dx_*^2]. \quad (35)$$

In the second line, we used $x = vr$, and in the last line, $x_* = v/x = 1/r$. We note that, in the last line, (t, x_*) correspond to the Poincaré coordinates (T, y) used in

FIG. 1 (color online). Mass m_{\pm}^2 for the AdS₂ solution for $l = 100$ and $v = 1$: The dotted curve is for the negative mass squared m_-^2 , while the dashed curve is for the positive mass squared $m_+^2 = m^2$. Since the AdS₂ solution with a positive charge q is valid for $K \leq l$ [17], the permitted region is $0 \leq K \leq 100$.

Ref. [30] to construct the Hadamard Green function for the Poincaré.

Finally, we wish to find a positive frequency mode for δF as

$$\delta F(t, x_*) = e^{-i\omega t} \delta f(x_*). \quad (36)$$

Then, the second-order Eq. (32) becomes

$$\frac{d^2}{dx_*^2} \delta f + \left[\omega^2 - \frac{(m^2 v + 2)}{x_*^2}\right] \delta f = 0, \quad (37)$$

whose solution is given by the Bessel functions

$$\delta f(x_*) = c_1 \sqrt{x_*} J_\nu(\omega x_*) + c_2 \sqrt{x_*} Y_\nu(\omega x_*), \quad (38)$$

where $\nu = \sqrt{m^2 v + \frac{9}{4}}$ satisfying $\nu^2 - 1/4 = m^2 v + 2$. Also, we observe that the event horizon is located at $r \rightarrow 0 (x_* \rightarrow \infty)$, while the infinity is located at $r \rightarrow \infty (x_* \rightarrow 0)$. In order to have the normalizable solution, we choose $c_2 = 0$ because $Y_\nu(\omega x_*)$ blows up at $x_* = 0$.

IV. CRITICAL GRAVITY IN TWO DIMENSIONS

At the critical point of $m^2 = 0 (K = l)$, (29) becomes the fourth-order differential equation

$$\left(\bar{\nabla}^2 - \frac{2}{v}\right)^2 \delta F^{4\text{th}} = 0. \quad (39)$$

In order to solve this equation, first of all, we observe that the Bessel function of order $\nu = 3/2$ satisfies the second-order equation for a massless scalar on AdS₂ spacetimes as follows:

$$\left(\bar{\nabla}^2 - \frac{2}{v}\right) \delta F_{\text{ml}} = 0, \quad (40)$$

whose normalizable solution is given by

$$\delta F_{\text{ml}}(t, x_*) = e^{-i\omega t} \delta f_{\text{ml}}(x_*), \quad (41)$$

where

$$\begin{aligned} \delta f_{\text{ml}}(x_*) &\simeq \sqrt{x_*} J_{3/2}(\omega x_*) \\ &= \sqrt{\frac{2}{\pi\omega}} \left[-\cos(\omega x_*) + \frac{\sin(\omega x_*)}{\omega x_*} \right]. \end{aligned} \quad (42)$$

At this stage, we remind the reader that two equations (39) and (40) with $K = l$ are the same equations

$$\left(\bar{\nabla}^2 - \frac{2}{v}\right)^2 h = 0, \quad \left(\bar{\nabla}^2 - \frac{2}{v}\right) \varphi = 0 \quad (43)$$

for the graviton and dilaton as found from the 3D Einstein gravity with $K = 0$ [27]. Here we observe the important correspondence as

$$\delta F_{\text{ml}} \leftrightarrow \varphi, \quad \delta F^{4\text{th}} \leftrightarrow h. \quad (44)$$

In the 3D linearized Einstein gravity, one confirms the connection between dilaton and dual scalar

$$\frac{\varphi}{u} = -\delta F. \quad (45)$$

This means that there are no propagating massive modes at the critical point, showing apparently that all modes of h , φ , and δF from the 3D Einstein gravity are gauge artefacts. However, it was proposed that any critical gravity has a new field on AdS spacetimes. In order to explore this idea on the AdS₂ spacetimes, we consider a positive frequency fourth-order field

$$\delta F^{4\text{th}}(t, x_*) = e^{-i\omega t} \delta f^{4\text{th}}(x_*). \quad (46)$$

Then, the fourth-order Eq. (39) takes the form

$$\left[\frac{d^2}{dx_*^2} + \left(\omega^2 - \frac{2}{x_*^2} \right) \right]^2 \delta f^{4\text{th}} = 0. \quad (47)$$

Replacing $\omega x_* = \omega/r$ by r_* and considering

$$\delta f^{4\text{th}}(r_*) = g(r_*) \delta f_{\text{ml}}(r_*), \quad (48)$$

(47) reduces to the second-order equation for $g(r_*)$ as

$$[g''(r_*) - 1] = -\frac{2\delta f'_{\text{ml}}(r_*)}{\delta f_{\text{ml}}(r_*)} g'(r_*), \quad (49)$$

where the prime $'$ denotes the differentiation with respect to its argument. Plugging (42) into (49) leads to the exact solution for $g(r_*)$,

$$g(r_*) = C_2 + \frac{2C_1 \cos(r_*) + r_*(r_* + 2C_1) \sin(r_*)}{2[r_* \cos(r_*) - \sin(r_*)]} \quad (50)$$

with two undetermined parameters C_1 and C_2 . Hereafter we set $C_1 = -1$ and $C_2 = 1$ for simplicity. Now, making use of the two identities

$$\begin{aligned} \sin(r_*) &= \sqrt{\frac{\pi}{2}} \left(\frac{3}{2\sqrt{x}} J_{3/2}(r_*) + \sqrt{r_*} J'_{3/2}(r_*) \right), \\ \cos(r_*) &= \sqrt{\frac{\pi}{2}} \left(\frac{(3-2r_*^2)}{2r_*^{3/2}} J_{3/2}(r_*) + \frac{1}{\sqrt{r_*}} J'_{3/2}(r_*) \right), \end{aligned} \quad (51)$$

we have finally obtained a solution to the fourth-order Eq. (47) as

$$\begin{aligned} \delta f^{4\text{th}}(r_*) &= -\left(\frac{3 + r_*^2 - \frac{1}{2} r_*^3}{2r_*^{5/2}} \right) J_{3/2}(r_*) \\ &\quad - \left(\frac{1 + r_*^2 + \frac{1}{2} r_*^3}{r_*^{3/2}} \right) J'_{3/2}(r_*), \end{aligned} \quad (52)$$

where $J'_{3/2}(r_*)$ can be expressed in terms of the lower order Bessel functions as

$$J'_{3/2}(r_*) = \left(1 - \frac{3}{r_*^3} \right) J_{1/2} + \frac{2}{2r_*^{3/2}} J_{-1/2}. \quad (53)$$

This shows that $J'_{3/2}(r_*)$ does not contain any singularity at infinity $r = \infty (r_* = 0)$. Figure 2(a) shows its behavior on r_* clearly. To see it more explicitly, $g(r_*)$ takes a series form near $r_* \sim 0 (r \rightarrow \infty)$:

$$\begin{aligned} g(r_*) &\simeq -\frac{3}{r_*^3} - \frac{9}{5r_*} - \frac{1}{2} + \frac{36}{175} r_* + \frac{1}{10} r_*^2 \\ &\quad + \frac{47}{7875} r_*^3 + \frac{1}{350} r_*^4 \dots \end{aligned} \quad (54)$$

Therefore, $\delta f^{4\text{th}}(r_*)$ shows a negative infinity as

$$-\frac{1}{r_*} \quad \text{as } r_* \rightarrow 0 \quad (55)$$

by observing the first term of

$$\begin{aligned} \delta f^{4\text{th}}(r_*) &= g(r_*) \delta f_{\text{ml}}(r_*) \\ &\simeq \sqrt{\frac{2}{\pi}} \left(-\frac{1}{r_*} - \frac{r_*}{2} - \frac{r_*^2}{6} + \frac{r_*^3}{8} + \frac{r_*^4}{20} - \frac{r_*^5}{144} - \frac{r_*^6}{336} \dots \right). \end{aligned} \quad (56)$$

For $C_1 = -1$ and $C_2 = 1$, we have a positive infinity of $\delta f^{4\text{th}}(r_*) \rightarrow \frac{1}{r_*}$ as $r_* \rightarrow 0$.

FIG. 2 (color online). Graphs of two functions $\delta f^{4\text{th}}(r_*)$ and the logarithmic partner $\delta f_{\text{log}}^{4\text{th}}(r_*)$ of a normalizable function $\delta f_{\text{ml}}(r_*) = \sqrt{r_*} J_{3/2}(r_*)$. Although the former is truly a solution to the fourth-order Eq. (47), it shows singular behavior at infinity of $r \rightarrow \infty (r_* \rightarrow 0)$, which may not be acceptable as a true solution. On the other hand, even though the logarithmic partner $\delta f_{\text{log}}^{4\text{th}}(r_*)$ approaches zero at $r_* = 0$, it is unlikely a solution to the fourth-order Eq. (47).

On the other hand, inspired by the log gravity [6,25], we suggest that a solution to the fourth-order Eq. (47) may take the form as a logarithmic partner of δF_{ml} [31]:

$$\delta F_{\text{log}}^{4\text{th}}(r_*) = e^{-i\omega t} \delta f_{\text{log}}^{4\text{th}}(r_*), \quad (57)$$

where

$$\begin{aligned} \delta f_{\text{log}}^{4\text{th}}(r_*) &= \frac{\partial}{\partial m^2} \{ \sqrt{r_*} J_\nu(r_*) \}_{m^2=0} \\ &= \frac{v\sqrt{r_*}}{3} \left[J_{3/2}(r_*) \ln(r_*/2) - \left(\frac{r_*}{2}\right)^{3/2} \right. \\ &\quad \left. \times \sum_{k=0}^{\infty} (-1)^k \frac{\psi(5/2+k)}{\Gamma(5/2+k)} \frac{(\frac{1}{4}r_*^2)^k}{k!} \right]. \end{aligned} \quad (58)$$

Here $\Gamma(z)$ is the gamma function and $\psi(z)$ is a digamma function defined by $\psi(z) = \frac{d \ln \Gamma(z)}{dz}$. Figure 2(b) describes $\delta f_{\text{log}}^{4\text{th}}(r_*)$. In the case of $r_* \rightarrow 0$, one has a series form for $\delta f_{\text{log}}^{4\text{th}}(r_*)$ as

$$\begin{aligned} \delta f_{\text{log}}^{4\text{th}}(r_*) &\simeq \frac{v}{27} \sqrt{\frac{2}{\pi}} \left([-8 + 3\gamma + 3\ln(2r_*)] r_*^2 \right. \\ &\quad \left. - \frac{[-46 + 15\gamma + 15\ln(2r_*)] r_*^4}{50} \right. \\ &\quad \left. + \frac{[-352 + 105\gamma + 105\ln(2r_*)] r_*^6}{9800} + \dots \right) \end{aligned} \quad (59)$$

with γ the Euler constant. From this form, we find that $\delta f_{\text{log}}^{4\text{th}}(r_*)$ approaches zero as $r_* \rightarrow 0$ even though the logarithmic terms are present. Applying the l'Hospital's rule to $r_*^n \ln(r_*/2)$ with $n \geq 1$ [equivalently, $J_{3/2}(r_*) \ln(r_*/2)$] as $r_* \rightarrow 0$, one finds immediately that these approach 0. This shows clearly a different divergent behavior from (55). Unfortunately, it is unlikely that $\delta f_{\text{log}}^{4\text{th}}(r_*)$ satisfies the fourth-order Eq. (47). Hence we exclude it as a solution at the critical point.

Since the solution to the fourth-order solution (52) is singular at $r_* \rightarrow 0$ ($r \rightarrow \infty$), it has a problem to be considered as the normalizable function at infinity. Hence we need to take care of the divergence of $\frac{1}{r_*}$ as $r_* \rightarrow 0$ (equivalently, r as $r \rightarrow \infty$).

On the other hand, we may choose the second kind of Bessel function $Y_{3/2}$ as a solution of the second-order equation for a massless scalar on the AdS₂ spacetimes even if it belongs to the nonnormalizable function at infinity as

$$\begin{aligned} \delta \tilde{f}_{\text{ml}}(x_*) &\simeq \sqrt{r_*} Y_{3/2}(\omega x_*) \\ &= \sqrt{\frac{2}{\pi\omega}} \left[-\sin(\omega x_*) - \frac{\cos(\omega x_*)}{\omega x_*} \right]. \end{aligned} \quad (60)$$

After replacing $\omega x_* = \omega/r$ by r_* , and solving (49), we have

$$\tilde{g}(r_*) = \tilde{C}_2 + \frac{\tilde{C}_1 \sin(r_*) - r_*(2r_* + \tilde{C}_1) \cos(r_*)}{4[\cos(r_*) + r_* \sin(r_*)]} \quad (61)$$

instead of (50). Near $r_* \sim 0$, we have a regular behavior as

$$\tilde{g}(r_*) \simeq 1 - \frac{r_*^2}{2} + \frac{r_*^3}{12} + \frac{r_*^4}{2} - \frac{r_*^5}{20} - \frac{r_*^6}{3} \dots, \quad (62)$$

with $\tilde{C}_1 = \tilde{C}_2 = 1$. Making use of the two identities

$$\begin{aligned} \sin(r_*) &= \sqrt{\frac{\pi}{2}} \left[\frac{(3-2r_*^2)}{2r_*^{3/2}} Y_{3/2}(r_*) + \frac{1}{\sqrt{r_*}} Y'_{3/2}(r_*) \right], \\ \cos(r_*) &= -\sqrt{\frac{\pi}{2}} \left[\frac{3}{2\sqrt{r_*}} Y_{3/2}(r_*) + \sqrt{r_*} Y'_{3/2}(r_*) \right], \end{aligned} \quad (63)$$

we find another solution to the fourth-order Eq. (47) as

$$\delta \tilde{f}^{4\text{th}}(r_*) = \left(\frac{-3 - r_*^2 + 2r_*^3}{8r_*^{5/2}} \right) Y_{3/2}(r_*) - \left(\frac{1 + r_*^2 + 2r_*^3}{4r_*^{3/2}} \right) Y'_{3/2}(r_*). \quad (64)$$

However, Fig. 3(a) shows its singular behavior as $r_* \rightarrow 0$, too. Near $r_* \sim 0$ ($r \rightarrow \infty$), one has a divergence of $-\frac{1}{0}$ as

$$\begin{aligned} \delta \tilde{f}^{4\text{th}}(r_*) &= \tilde{g}(r_*) \delta \tilde{f}_{\text{ml}}(r_*) \\ &\simeq \sqrt{\frac{2}{\pi}} \left(-\frac{1}{r_*} - \frac{r_*^2}{12} - \frac{r_*^3}{8} + \frac{r_*^4}{120} + \frac{r_*^5}{72} - \frac{r_*^6}{3360} \dots \right). \end{aligned} \quad (65)$$

Finally, introducing the log gravity, a suggested solution as a logarithmic partner of $\delta \tilde{f}_{\text{ml}}$ takes the form [31] of

$$\delta \tilde{F}_{\text{log}}^{4\text{th}}(r_*) = e^{-i\omega t} \delta \tilde{f}_{\text{log}}^{4\text{th}}(r_*), \quad (66)$$

where

$$\begin{aligned} \delta \tilde{f}_{\text{log}}^{4\text{th}}(r_*) &= \frac{\partial}{\partial m^2} \{ \sqrt{r_*} Y_\nu(r_*) \}_{m^2=0} \\ &= \frac{v\sqrt{r_*}}{3} \left[\cot[3\pi/2] \left(J_{3/2}(r_*) \ln(r_*/2) \right. \right. \\ &\quad \left. \left. - \left(\frac{r_*}{2}\right)^{3/2} \sum_{k=0}^{\infty} (-1)^k \frac{\psi(5/2+k)}{\Gamma(5/2+k)} \frac{(\frac{1}{4}r_*^2)^k}{k!} - \pi Y_{3/2}(r_*) \right) \right. \\ &\quad \left. + \csc[3\pi/2] \left(J_{-3/2}(r_*) \ln(r_*/2) - \left(\frac{r_*}{2}\right)^{-3/2} \right. \right. \\ &\quad \left. \left. \times \sum_{k=0}^{\infty} (-1)^k \frac{\psi(-1/2+k)}{\Gamma(-1/2+k)} \frac{(\frac{1}{4}r_*^2)^k}{k!} - \pi J_{3/2}(r_*) \right) \right] \\ &= \frac{v}{3} \left(\frac{3a}{\sqrt{2\pi}} r_* - \pi \sqrt{r_*} J_{3/2}(r_*) - \ln(r_*/2) Y_{3/2}(r_*) \right) \end{aligned} \quad (67)$$

with $a = 0.616108$. Figure 3(b) indicates $\delta \tilde{f}_{\text{log}}^{4\text{th}}(r_*)$ is singular at $r_* = 0$. To show it explicitly, one finds a series expansion of $\tilde{f}_{\text{log}}^{4\text{th}}(r_*)$ as

FIG. 3 (color online). Graphs of two functions $\delta\tilde{f}^{4\text{th}}(r_*)$ and the logarithmic partner $\delta\tilde{f}_{\log}^{4\text{th}}(r_*)$ of a nonnormalizable function $\delta\tilde{f}_{\text{ml}}(r_*) = \sqrt{r_*}Y_{3/2}(r_*)$. Although the former is a solution to the fourth-order Eq. (47), it shows singular behavior at infinity of $r \rightarrow \infty$ ($r_* \rightarrow 0$), which may not be acceptable as a true solution. On the other hand, the logarithmic partner $\delta\tilde{f}_{\log}^{4\text{th}}(r_*)$ shows a singular behavior at $r_* = 0$ and it is unlikely a solution to the fourth-order Eq. (47).

$$\begin{aligned} \tilde{f}_{\log}^{4\text{th}}(r_*) \simeq v \sqrt{\frac{2}{\pi}} \left[\left(\frac{1}{3r_*} + \frac{1}{6}r_* - \frac{1}{24}r_*^3 + \frac{1}{432}r_*^5 \right) \ln(r_*/2) \right. \\ \left. + \left(\frac{a}{2}r_* - \frac{\pi}{9}r_*^2 + \frac{\pi}{90}r_*^4 \right) + \dots \right]. \end{aligned} \quad (68)$$

Here we note that the first term in $\ln(r_*/2)$ shows a singular behavior as $r_* \rightarrow 0$, while the remaining terms make a finite graph as an oscillatory increasing function for large r_* .

V. DISCUSSIONS

We have studied the critical gravity in AdS₂ spacetimes, which was obtained from the topologically massive gravity in three dimensions by using the Kaluza-Klein dimensional reduction. We have performed the perturbation analysis around the AdS₂, which corresponds to the near-horizon geometry of the extremal BTZ black hole obtained from the topological massive gravity with identification upon uplifting three dimensions. A physically massive scalar mode δF satisfies the second-order differential equation away from the critical point of $K = l$, while it satisfies the fourth-order equation at the critical point. At the critical point, the 2DTMG_Λ turns out to be the 2D dilaton gravity including the Maxwell field obtained from the 3D Einstein gravity, which shows implicitly that there are no propagating modes.

Based on that the critical gravity has a new field in AdS spacetimes, we have exactly solved the fourth-order equation, and compared it with the log-gravity ansatz in two dimensions. The critical gravity is described by $\delta f^{4\text{th}}$ (52) precisely; however, it becomes divergent linearly ($r \rightarrow \infty$) as the infinity of $r_* = 0$ ($r = \infty$) is approached. This means

that the solution to the fourth-order equation is not a precisely normalizable function and, thus, it requires introducing an appropriate boundary condition which accommodates a linear divergence.

More importantly, it has turned out that the critical gravity could not be described by the massless scalar δf_{ml} and its logarithmic partner $\delta f_{\log}^{4\text{th}}$ (58), which approaches zero as $r_* \rightarrow 0$. This is so because $\delta f_{\log}^{4\text{th}}$ unlikely satisfies the fourth-order equation.

Finally, we would like to comment that the linearized higher dimensional critical gravities were widely investigated in the AdS spacetimes [26] but the nonunitarity issue of the log gravity is still not resolved, indicating that any log gravity suffers from the ghost problem. Furthermore, the critical gravity on the Schwarzschild-AdS black hole has suffered from the ghost problem when the cross term E_{cross} is nonvanishing [32].
