(Received 27 October 2011; published 22 March 2012)

We construct some examples of  $D = 3$ ,  $\mathcal{N} = 4$  GW theory and  $\mathcal{N} = 5$  superconformal Chern-Simons matter theory by using the covariantly constant curvature of a quaternionic-Kähler manifold to construct the symplectic 3-algebra in the theories. Comparing with the previous theories, the  $\mathcal{N} = 4, 5$  theories constructed in this way possess a local  $Sp(2n)$  symmetry and a diffeomorphism symmetry associated with the quaternionic-Kähler manifold. We also construct a generalized  $\mathcal{N} = 8$  BLG theory by utilizing the dual curvature operator of a maximally symmetric space of dimension 4 to construct the Nambu 3-algebra. Comparing with the previous  $\mathcal{N} = 8$  BLG theory, the theory has a diffeomorphism invariance and a local  $SO(4)$  invariance associated with the symmetric space.

## I. INTRODUCTION AND SUMMARY

In the last three years, the extended ( $\mathcal{N} \geq 4$ ) supersymmetric Chern-Simons-matter (CSM) theories in 3D have been constructed by using both ordinary Lie algebras and 3-algebras [1–15]. In particular, symplectic 3-algebra provides a unified framework for constructing all  $\mathcal{N} \geq 4$  CSM theories [12]. Using superalgebra to realize the 3-algebra, one can recover all known examples of the extended  $\mathcal{N} \geq 4$  CSM theories [9,11,12] and construct several new classes of  $\mathcal{N} = 4$  theories as well [13].

A 3-algebra is a triple system. Since a covariantly constant curvature tensor also defines a triple system, it is natural to ask whether it can be used to construct the 3-algebras in the extended CSM theories. In this paper, we demonstrate that at least some special curvature tensor can be used to construct the structure constants of the 3-algebra. Specifically, we use the covariantly constant curvature tensor of a manifold admitting a quaternion structure to construct the symplectic 3-algebra in the  $\mathcal{N} = 4$  GW theory and  $\mathcal{N} = 5$  theory; the symmetry generated by the curvature tensor is partially gauged, and the resulting gauge group is  $Sp(2n)$ . Comparing to the original  $\mathcal{N} = 4, 5$  theories [3,7], the theories constructed in this way have a *local  $Sp(2n)$  symmetry* and a *diffeomorphism symmetry* related to the (quaternionic-Kähler) manifold.

We demonstrate that the dual curvature tensor of a  $4D$  (internal) manifold also defines a triple system, providing that the curvature tensor is covariantly constant. Furthermore, if the dual curvature tensor is totally anti-symmetric, we can use the triple system constructed by the dual curvature operator to realize the Nambu 3-algebra in the  $\mathcal{N} = 8$  BLG theory. The  $\mathcal{N} = 8$  BLG theory constructed in this way is a generalization of the previous theory in Ref. [1,2], in that it has a *diffeomorphism*

*invariance* and a *local  $SO(4)$  symmetry* associated with the  $4D$  internal space. The gauge group generated by the dual curvature 3-algebra is still  $SO(4)$ . It would be nice to analyze this generalized  $\mathcal{N} = 8$  BLG theory further.

The paper is organized as follows. In Sec. II, we briefly review the symplectic 3-algebra, and utilize the covariantly constant curvature tensor of a quaternionic-Kähler manifold to construct the symplectic 3-algebra in the  $\mathcal{N} = 4$  GW theory and  $\mathcal{N} = 5$  theory [12]. In Sec. III, we use the dual curvature tensor of a maximally symmetric  $4D$  space to construct the Nambu 3-algebra in the  $\mathcal{N} = 8$  theory. In Appendix A, we briefly review the  $\mathcal{N} = 4, 5, 8$  CSM theories. Our conventions are summarized in Appendix B.

## II. CURVATURE TENSOR AND SYMPLECTIC 3-ALGEBRA

### A. A review of symplectic 3-algebra

In this section, we will review the symplectic 3-algebra [9,11]. A symplectic 3-algebra is a complex vector space, equipped with the 3-bracket

$$[T_a, T_b; T_c] = f_{abc}{}^d T_d, \quad (2.1)$$

where  $T_a$  ( $a = 1, \dots, 2L$ ) is a set of basis generators. We assume that the structure constants are symmetric in the first two indices, i.e.

$$f_{abc}{}^d = f_{bac}{}^d. \quad (2.2)$$

The structure constants are required to satisfy the fundamental identity

$$f_{abe}{}^g f_{gfdc} + f_{abf}{}^g f_{egcd} - f_{efd}{}^g f_{abgc} - f_{efc}{}^g f_{abdg} = 0. \quad (2.3)$$

The transformation of a 3-algebra valued field  $X = X^a T_a$  is defined as

$$\delta_{\bar{\Lambda}} X^d = \Lambda^{ab} f_{abc}{}^d, \quad (2.4)$$

\*famin.chen@gmail.com

where  $\Lambda^{ab}$  is a set of parameters, satisfying the reality condition

$$\Lambda_{ba}^* = \Lambda^{ab} = \omega^{ac} \omega^{bd} \Lambda_{cd}. \quad (2.5)$$

To define a symplectic 3-algebra, we require the transform (2.4) to preserve both the antisymmetric form  $\omega(X, Y) = \omega_{ab} X^a Y^b$  and the Hermitian form  $h(X, Y) = X^{*a} Y^b$  simultaneously:

$$\delta_{\bar{\Lambda}} \omega(X, Y) = \delta_{\bar{\Lambda}} h(X, Y) = 0. \quad (2.6)$$

Together with (2.2), (2.5), and (2.9) below, Eqs. (2.6) imply that the structure constants satisfy the symmetry conditions

$$f_{abcd} = f_{bacd} = f_{abdc} = f_{cdab}, \quad (2.7)$$

and obey the reality condition

$$f_{abcd}^* = f^{abcd} = \omega^{ae} \omega^{bf} \omega^{cg} \omega^{dh} f_{efgh}. \quad (2.8)$$

We have used the invariant antisymmetric tensor  $\omega_{ab}$  to lower a 3-algebra index, i.e.  $f_{abcd} \equiv \omega_{de} f_{abc}^e$ . The inverse of  $\omega_{ab}$  is denoted as  $\omega^{bc}$ , satisfying  $\omega_{ab} \omega^{bc} = \delta_a^c$ . Also, to close the  $\mathcal{N} = 4, 5$  superalgebras, the structure constants must satisfy the linear constraint equation

$$f_{(abc)d} = 0. \quad (2.9)$$

## B. Curvature tensor and structure constants of 3-algebra

In this section, we will demonstrate that the covariantly constant curvature tensor of a quaternionic-Kähler manifold can be used to construct the structure constants of the symplectic 3-algebra. Let  $(M, g)$  be a  $4n$ -dimensional manifold, which will be called an internal space. Assume that the metric  $g$  is nondegenerate and positive definite. Suppose that the curvature tensor is covariantly constant, i.e.  $\nabla_I R_{JKLM} = 0$ , with the index  $I$  running over  $1, \dots, 4n$ . Then the integrability condition  $[\nabla_I, \nabla_J] R_{KLMN} = 0$  gives

$$R^O_{KIJ} R_{OLMN} + R^O_{LIJ} R_{KOMN} + R^O_{MIJ} R_{KLOn} + R^O_{NIJ} R_{KLMO} = 0. \quad (2.10)$$

On the other hand, it is well known that the curvature operator maps three vectors into one vector, that is,

$$R(e_I, e_J) e_K = R_{IJK}{}^L e_L, \quad (2.11)$$

where  $e_I$  is a set of basis vectors satisfying

$$g(e_I, e_J) = g_{IJ}. \quad (2.12)$$

Equations (2.10) and (2.11) actually define a triple system: using the curvature operator to construct the 3-bracket

$$[e_I, e_J; e_K] \equiv R(e_I, e_J) e_K = R_{IJK}{}^L e_L, \quad (2.13)$$

we see that Eq. (2.10) is equivalent the equation

$$\begin{aligned} [e_I, e_J; [e_M, e_N; e_K]] \\ = [[e_I, e_J; e_M], e_N; e_K] + [e_M, [e_I, e_J; e_N]; e_K] \\ + [e_M, e_N; [e_I, e_J; e_K]], \end{aligned} \quad (2.14)$$

which plays the role of fundamental identity (FI). We call the Lie triple system defined by (2.12), (2.13), and (2.14) a *curvature 3-algebra*. The curvature 3-algebra can generate an  $SO(4n)$  symmetry; the corresponding symmetry group is of course the holonomy group. Writing  $R_{IJKL}$  as  $(R_{IJ})_{KL}$ , we can think of that  $(R_{IJ})$  are a set of matrices,<sup>1</sup> with  $(R_{IJ})_{KL}$  the matrix elements. Then the matrices  $(R_{IJ})$  are indeed a set of  $SO(4n)$  generators, since they preserve the symmetric and nondegenerate inner product  $g_{KL}$  in the sense that  $[\nabla_I, \nabla_J] g_{KL} = R_{IJK}{}^M g_{ML} + R_{IJL}{}^M g_{KM} = 0$ , i.e. the matrix elements  $(R_{IJ})_{KL}$  are antisymmetric in  $KL$ . The structure constants of the algebra can be read off from (2.10).

Assume that the manifold admits the quaternion structure or the triplet of complex structures

$$(J^i)_I{}^J = -i e_I^{aA} (\sigma^i)_A{}^B e_{J aB}, \quad (2.15)$$

where  $(\sigma^i)_A{}^B$  ( $i = 1, 2, 3; A = 1, 2$ ) are the pauli matrices. The vielbein  $e_I^{aA}$  satisfies

$$e_I^{aA} e_{J aA} = g_{IJ}, \quad e_I^{aA} e^{I bB} = \omega^{ab} \epsilon^{AB}, \quad (2.16)$$

where  $e^{I bB} = g^{IJ} e_J^{bB}$ . Here  $\epsilon^{AB}$  is the antisymmetric tensor of  $Sp(2) \cong SU(2)$ , and the antisymmetric tensor  $\omega^{ab}$  will be identified as the symplectic form of  $Sp(2n)$ . We denote the inverse of  $\epsilon^{AB}$  as  $\epsilon_{BC}$ :  $\epsilon^{AB} \epsilon_{BC} = \delta_C^A$ . The inverse of  $\omega^{ab}$  is  $\omega_{bc}$  satisfying  $\omega^{ab} \omega_{bc} = \delta_c^a$ . Since  $g_{IJ}$  is real, the vielbein must obey the reality condition  $e_{I aA} = \epsilon_{AB} \omega_{ab} e_I^{bB}$ . The quaternion algebra reads  $J^i J^j = \epsilon^{ijk} J^k - \delta^{ij}$ . The triplet of complex structures, vielbein and antisymmetric tensors must be covariant constants,

$$\nabla_I (J^i)_J{}^K = \nabla_I e_J^{aA} = \nabla_I \epsilon^{AB} = \nabla_I \omega^{ab} = 0. \quad (2.17)$$

The integrability condition

$$[\nabla_I, \nabla_J] e_K^{aA} = R_{IJK}{}^L e_L^{aA} + R_{IJ}{}^a{}_b e_K^{bA} + R_{IJ}{}^A{}_B e_K^{aB} = 0 \quad (2.18)$$

suggests that the curvature tensor  $R_{IJK}{}^L$  can be decomposed into two parts<sup>2</sup>:

$$\begin{aligned} e_{aA}^I e_{bB}^J e_{cC}^K e_{dD}^L R_{IJKL} \\ = R_{aA, bB, cC, dD} = \omega_{ab} \omega_{cd} R_{ABCD} + \epsilon_{AB} \epsilon_{CD} R_{abcd}. \end{aligned} \quad (2.19)$$

The symmetry properties of  $R_{IJKL}$  ( $R_{IJKL} = -R_{JKIL} = -R_{IJLK} = R_{KLJI}$ ) imply that  $R_{abcd}$  and  $R_{ABCD}$  obey the symmetry conditions

$$R_{abcd} = R_{bacd} = R_{abdc} = R_{cdab}, \quad (2.20)$$

<sup>1</sup>Here  $(R_{IJ})$  is *not* the Ricci tensor  $R_{IJ}$ .

<sup>2</sup>For a general discussion of the curvature of quaternionic-Kähler manifolds, see Ref. [16].

$$R_{ABCD} = R_{BACD} = R_{ABDC} = R_{CDAB}. \quad (2.21)$$

The integrability condition

$$[\nabla_I, \nabla_J]\omega^{ab} = R_{IJ}{}^a{}_c \omega^{cb} + R_{IJ}{}^b{}_c \omega^{ac} = 0 \quad (2.22)$$

implies that the matrix  $R_{IJ}{}^a{}_c$  (for fixed  $I$  and  $J$ ) is an  $Sp(2n)$  matrix. Similarly, for fixed  $I$  and  $J$ , the matrix  $R_{IJ}{}^A{}_B$  is a generator of the Lie algebra of  $Sp(2)$ . Later we will see, only the symmetry generated by  $R_{bd}{}^a{}_c$  will be gauged, meaning that we will gauge *part* of the full symmetry generated by  $R_{IJK}{}^L$ . By Eqs. (2.17) and (2.15), we learn that the pauli matrices must be covariantly constant as well, i.e.  $\nabla_{aA}(\sigma^i)_{EF} = 0$ . Defining

$$(\tau_{CD})_{EF} \equiv \sigma_{CD}^i \sigma_{EF}^i = \epsilon_{CE} \epsilon_{DF} + \epsilon_{CF} \epsilon_{DE}, \quad (2.23)$$

the integrability condition  $\omega^{ba}[\nabla_{aA}, \nabla_{bB}](\tau_{CD})_{EF} = 0$  gives

$$R_{ABC}{}^G(\tau_{GD})_{EF} + R_{ABD}{}^G(\tau_{CG})_{EF} + R_{ABE}{}^G(\tau_{CD})_{GF} + R_{ABF}{}^G(\tau_{CD})_{EG} = 0. \quad (2.24)$$

In accordance with the decomposition (2.19), Eq. (2.10) is decomposed into two equations

$$R_{abe}{}^g R_{gfc}d + R_{abf}{}^g R_{egcd} - R_{efd}{}^g R_{abgc} - R_{efc}{}^g R_{abdg} = 0, \quad (2.25)$$

$$R_{ABE}{}^G R_{GFCD} + R_{ABF}{}^G R_{EGCD} - R_{EFD}{}^G R_{ABCG} - R_{EFC}{}^G R_{ABDG} = 0. \quad (2.26)$$

It can be seen that (2.20) and (2.25) take exactly the same forms as that of (2.3) and (2.7), respectively. However, if we want to identify the structure constants  $f_{abcd}$  with  $R_{abcd}$ , we must make sure that  $R_{abcd}$  also obeys the linear constraint Eq. (2.9) and satisfies the reality condition (2.8). We will see that at least in some special case, these two requirements can be fulfilled. To see this, let us consider the algebraic property of the Riemann curvature tensor

$$R_{aA,bB,cC,dD} + R_{bB,cC,aA,dD} + R_{cC,aA,bB,dD} = 0. \quad (2.27)$$

Using the decomposition (2.19), Eq. (2.27) can be converted into

$$R_{abcd} \epsilon_{AB} \epsilon_{CD} + R_{bcad} \epsilon_{BC} \epsilon_{AD} + R_{cabd} \epsilon_{CA} \epsilon_{BD} + R_{ABCD} \omega_{ab} \omega_{cd} + R_{BCAD} \omega_{bc} \omega_{ad} + R_{CABD} \omega_{ca} \omega_{bd} = 0. \quad (2.28)$$

Let us solve for  $R_{ABCD}$  first; comparing (2.26) with (2.24), we find an obvious solution to these two equations:

$$R_{ABCD} = k(\tau_{AB})_{CD} = k(\epsilon_{AC} \epsilon_{BD} + \epsilon_{AD} \epsilon_{BC}), \quad (2.29)$$

where  $k$  is proportional to the (constant) curvature scalar  $R = g^{IJ} R_{IJ}$ . It can be seen that right hand side of (2.29) satisfies the symmetry conditions (2.21) and (2.26). Substituting Eq. (2.29) above into (2.28), we obtain

$$[R_{abcd} - R_{bcad} - k(\omega_{bc} \omega_{ad} - 2\omega_{ca} \omega_{bd} + \omega_{ab} \omega_{cd})] \epsilon_{AB} \epsilon_{CD} + [R_{cabd} - R_{bcad} + k(\omega_{bc} \omega_{ad} - 2\omega_{ab} \omega_{cd} + \omega_{ca} \omega_{bd})] \epsilon_{CA} \epsilon_{BD} = 0, \quad (2.30)$$

where we have used the identity  $\epsilon_{AB} \epsilon_{CD} = \epsilon_{AC} \epsilon_{BD} - \epsilon_{BC} \epsilon_{AD}$ . We observe that if the first line vanishes, then the second line vanishes automatically, and vice versa. We therefore need only to consider the equation

$$R_{abcd} - R_{bcad} - k(\omega_{bc} \omega_{ad} - 2\omega_{ca} \omega_{bd} - \omega_{ab} \omega_{cd}) = 0. \quad (2.31)$$

Under the condition  $R_{(abc)d} = 0$ , the solution is given by

$$R_{abcd} = k(\omega_{ac} \omega_{bd} + \omega_{ad} \omega_{bc}), \quad (2.32)$$

which is nothing but an  $Sp(2n)$  matrix (for fixed  $a$  and  $b$ ). Now it is straightforward to check that (2.32) obeys the linear constraint Eq. (2.9) and satisfies the reality condition (2.8): namely,  $R_{(abc)d} = 0$  and  $R_{abcd}^* = R^{abcd} = \omega^{ae} \omega^{bf} \omega^{cg} \omega^{dh} R_{efgh}$ . Hence  $R_{abcd}$  can be used to construct the structure constants of the symplectic 3-algebra. Substituting (2.29) and (2.32) into (2.19) determines  $k = \frac{R}{8n(n+2)}$ . Also by (2.29) and (2.32), we learn that our solution  $R_{aA,bB,cC,dD}$  is consisted of entirely by covariantly constant quantities such as  $\omega_{ab}$  and  $\epsilon_{AB}$ , so it must be also a covariantly constant tensor, i.e.  $\nabla_I R_{aA,bB,cC,dD} = 0$ . Setting  $f_{abcd} = R_{abcd}$  and substituting (2.32) into Eq. (A1) [Eq. (A5)] gives the  $\mathcal{N} = 4$  GW ( $N = 5$ ) theory with  $Sp(2n)$  gauge group.

It can be seen that the  $\mathcal{N} = 4$  action constructed here has the symmetries associated with the quaternionic-Kähler manifold:

(i) Diffeomorphism invariance<sup>3</sup>:

$$R'_{abcd}(q') = R_{abcd}(q), \quad Z'_\alpha{}^a(q') = Z_\alpha{}^a(q), \quad \psi'^a{}_\alpha(q') = \psi^a{}_\alpha(q), \quad A'^{ab}{}_\mu(q') = A^{ab}{}_\mu(q) \quad (2.33)$$

with  $q^I$  a set of local coordinates, and  $q^I \rightarrow q'^I$  an arbitrary coordinate transformation.

(ii) Local  $Sp(2n)$  symmetry:

$$\begin{aligned} \hat{Z}_\alpha{}^a(q) &= L^a{}_b(q) Z_\alpha{}^b(q), & \hat{\psi}^a{}_\alpha(q) &= L^a{}_b(q) \psi^b{}_\alpha(q), \\ \hat{A}^{ab}{}_\mu(q) &= L^a{}_c(q) L^b{}_d(q) A^{cd}{}_\mu(q), \\ \hat{f}_{abcd}(q) &= \hat{R}_{abcd}(q) \\ &= L^a{}_e(q) L^b{}_f(q) L^c{}_g(q) L^d{}_h(q) R_{efgh}(q) \\ &= R_{abcd}(q), \end{aligned} \quad (2.34)$$

where  $L^a{}_e(q) = \omega_{ac} \omega^{ed} L^c{}_d(q)$ , and  $L^a{}_b(q)$  satisfies

$$L^c{}_a(q) L^d{}_b(q) \omega_{cd} = \omega_{ab}. \quad (2.35)$$

<sup>3</sup>The indices  $\alpha = 1, 2$  and  $\dot{\alpha} = 1, 2$  below denote the bifundamental representation of the R-symmetry group  $SU(2) \times SU(2)$  (see Sec. A1).

In the last equation of (2.34), we have used (2.32) and (2.35).

Similarly, the  $\mathcal{N} = 5$  theory also possesses the diffeomorphism symmetry and the local  $Sp(2n)$  symmetry associated with the internal space.

However, we emphasize that the  $\mathcal{N} = 4$  GW theory constructed here is *not* a conventional nonlinear sigma model like the one in Ref. [3]: in our construction, the scalar fields  $Z_\alpha^a$  are a set of *complex vectors* of the *quaternionic-Kahler manifold*, while in the original  $\mathcal{N} = 4$  GW nonlinear sigma model, the scalar fields are a set of *local coordinates* of the target space being a  $4n$ -dimensional *hyper-Kahler manifold*. Also, the gauge symmetry of the  $\mathcal{N} = 4$  GW theory constructed here is generated by the curvature 3-algebra or the *holonomy algebra* of the internal space, while in the  $\mathcal{N} = 4$  GW nonlinear sigma model, the gauge symmetry is generated by the *Killing vectors* of the target space.

### III. DUAL CURVATURE TENSOR AND GENERALIZED $\mathcal{N} = 8$ BLG THEORY

In this section, we will demonstrate that the Nambu 3-algebra can be realized by utilizing the dual curvature operator of a  $4D$  maximally symmetric space. We call this symmetric space an internal space. A generalized  $\mathcal{N} = 8$  BLG theory possessing a diffeomorphism invariance and a local  $SO(4)$  symmetry related to the internal space can be constructed by virtue of the dual curvature tensor.

In  $4D$ , the dual curvature tensor is defined as

$$\tilde{R}_{abcd} = \frac{1}{2} \sqrt{g} \varepsilon_{abef} R^{ef}{}_{cd}, \quad (3.1)$$

where  $g = \det(g_{ab})$ , and  $\sqrt{g} \varepsilon_{abef}$  is the totally antisymmetric tensor.<sup>4</sup> (We assume that the metric is nondegenerate and positive definite.) If the curvature tensor  $R_{efcd}$  satisfies  $\nabla_g R_{efcd} = 0$ , we must have  $\nabla_g \tilde{R}_{abcd} = 0$  on account of that  $\sqrt{g} \varepsilon_{abef}$  is always a covariant constant. To prove that  $\nabla_g (\sqrt{g} \varepsilon_{abef}) = 0$ , we introduce a set of vielbein fields  $e_i^a$  ( $i = 1, \dots, 4$ ) satisfying  $\delta^{ij} e_i^a e_j^b = g^{ab}$  and  $g_{ab} e_i^a e_j^b = \delta_{ij}$ . Now the totally antisymmetric tensor can be converted into a constant  $\varepsilon_{ijkl} = e_i^a e_j^b e_k^c e_l^d \sqrt{g} \varepsilon_{abcd}$  (our convention is that  $\varepsilon^{ijkl} = \delta^{im} \delta^{jn} \delta^{ko} \delta^{lp} \varepsilon_{mnop} = \varepsilon_{ijkl}$ ), and its covariant derivative is given by

$$\begin{aligned} \nabla_m \varepsilon_{ijkl} = & e_m^a (\partial_a \varepsilon_{ijkl} - \omega_a{}^n{}_i \varepsilon_{njkl} - \omega_a{}^n{}_j \varepsilon_{inlk} \\ & - \omega_a{}^n{}_k \varepsilon_{ijnl} - \omega_a{}^n{}_l \varepsilon_{ijkn}). \end{aligned} \quad (3.2)$$

The spin connection can be written as  $\omega_a{}^n{}_i = \frac{1}{2} \omega_a{}^{op} (\sigma_{op})^n{}_i$ , with  $(\tau_{op})^n{}_i = \delta_o^p \delta_{pi} - \delta_{oi} \delta_p^n$  the  $SO(4)$  matrices. Since  $\partial_a \varepsilon_{ijkl} = 0$ , the right hand side of (3.2) becomes

<sup>4</sup>Here  $a = 1, \dots, 4$  is a tangent vector index, *not* an  $Sp(2n)$  fundamental index of the last section. We hope this will not cause any confusion.

$$\begin{aligned} -\frac{1}{2} e_m^a \omega_a{}^{op} [(\tau_{op})^n{}_i \varepsilon_{njkl} + (\tau_{op})^n{}_j \varepsilon_{inlk} + (\tau_{op})^n{}_k \varepsilon_{ijnl} \\ + (\tau_{op})^n{}_l \varepsilon_{ijkn}]. \end{aligned} \quad (3.3)$$

The quantity in the bracket is nothing but the variation of  $\varepsilon_{ijkl}$  under the transformation generated by  $(\tau_{op})$ ; it vanishes due to the fact that  $\varepsilon_{ijkl}$  is  $SO(4)$ -invariant. Alternatively, one can write the first term in the bracket of (3.3) as

$$(\tau_{op})_{ni} \varepsilon_{njkl} = \left( \frac{1}{2} \varepsilon_{msop} \varepsilon^{ms}{}_{ni} \right) \varepsilon_{njkl}. \quad (3.4)$$

Substituting  $\varepsilon_{opms} \varepsilon^{njkl} = \delta_o^n \delta_p^j \delta_m^k \delta_s^l$  into the right hand side of (3.4) proves that (3.3) is zero. This completes the proof that  $\nabla_m \varepsilon_{ijkl} = 0$ , meaning that the tensor  $\sqrt{g} \varepsilon_{abef}$  is a covariant constant. Assuming that  $\nabla_a R_{cdef} = 0$ , and multiplying the integrability condition  $[\nabla^g, \nabla^h] \tilde{R}_{cdef} = 0$  by  $\frac{1}{2} \times \sqrt{g} \varepsilon_{abgh}$ , we obtain

$$\tilde{R}_{abe}{}^g \tilde{R}_{gfdc} + \tilde{R}_{abf}{}^g \tilde{R}_{egcd} - \tilde{R}_{efd}{}^g \tilde{R}_{abcg} - \tilde{R}_{efc}{}^g \tilde{R}_{abdg} = 0. \quad (3.5)$$

On the other hand, we can construct a 3-bracket in terms of the dual curvature operator:

$$\{e_a, e_b, e_c\} \equiv \frac{1}{2} \sqrt{g} \varepsilon_{abef} R(e^e, e^f) e_c = \tilde{R}_{abc}{}^d e_d, \quad (3.6)$$

with  $e_a$  a set of basis vectors satisfying

$$g(e_a, e_b) = g_{ab}. \quad (3.7)$$

We now see that taking account of the inner product (3.7), Eq. (3.5) is equivalent to the fundamental identity

$$\begin{aligned} \{e_a, e_b, \{e_c, e_d, e_e\}\} = & \{\{e_a, e_b, e_c\}, e_d, e_e\} + \{e_c, \{e_a, e_b, e_d\}, e_e\} \\ & + \{e_c, e_d, \{e_a, e_b, e_e\}\}. \end{aligned} \quad (3.8)$$

We call the triple system defined by Eqs. (3.6), (3.7), and (3.8) a *dual curvature 3-algebra*. In Sec. II B, we have demonstrated that the curvature tensor of the  $4n$ -dimensional manifold can generate an  $SO(4n)$  symmetry. Based on the same reason, the dual curvature 3-algebra can generate an  $SO(4)$  symmetry.

If  $\tilde{R}_{abcd}$  is completely antisymmetric in all indices, the dual curvature 3-algebra is an obvious realization of the Nambu 3-algebra.<sup>5</sup> We now assume that  $\tilde{R}$  is totally antisymmetric. Since in  $4D$  the totally antisymmetric tensor is essentially unique, we must have  $\tilde{R}_{abcd} = k \sqrt{g} \varepsilon_{abcd}$ . Using Eq. (3.1), one can determine that

$$R_{efcd} = \frac{R}{12} (g_{ec} g_{fd} - g_{ed} g_{fc}). \quad (3.9)$$

Namely, the manifold is maximally symmetric and  $k$  is given by  $k = \frac{R}{12}$ , with  $R$  the curvature scalar, which must be a constant. Therefore our final result is

<sup>5</sup>If the inner product is Lorentzian in the sense that  $g^{ab} e_a^i e_b^j = \eta^{ij}$ , then it is a realization of the Lorentzian 3-algebra. But we do not consider this case in the current paper.

$$f_{abcd} = \tilde{R}_{abcd} = \frac{R}{12} \sqrt{g} \varepsilon_{abcd}. \quad (3.10)$$

$\tilde{R}_{abcd}$  being totally antisymmetric is a necessary condition for closing the  $\mathcal{N} = 8$  superalgebra. We now present an alternative derivation of (3.10). Since  $\tilde{R}_{abcd} = -\tilde{R}_{bacd} = -\tilde{R}_{abdc}$ ,  $\tilde{R}_{abcd}$  will be totally antisymmetric if  $\tilde{R}_{abcd} = -\tilde{R}_{acbd}$ . Multiplying both sides of the equation by  $\frac{1}{2\sqrt{g}} \varepsilon_{ef}^{ab}$  and using (3.1), we obtain

$$R_{efcd} = \left( \frac{1}{2\sqrt{g}} \varepsilon_{ef}^{ab} \right) \left( -\frac{1}{2} \sqrt{g} \varepsilon_{ac}^{gh} R_{ghbd} \right). \quad (3.11)$$

A short calculation gives

$$R_{efcd} + \frac{1}{3} (g_{fc} R_{ed} - g_{ec} R_{fd}) = 0. \quad (3.12)$$

In order that  $R_{efcd} = -R_{efdc}$ , we must require that  $g_{fc} R_{ed} - g_{ec} R_{fd} = -(g_{fd} R_{ec} - g_{ed} R_{fc})$ . Multiplying both sides by  $g^{cf}$  determines the Ricci tensor  $R_{ed}$  uniquely:  $R_{ed} = \frac{R}{4} g_{ed}$ . Substituting it into (3.12) gives (3.9). Combining (3.1) and (3.9), we obtain (3.10) again.

We see that the curvature tensor (3.9) indeed obeys the crucial equation  $\nabla_b R_{efcd} = 0$ . The dual curvature tensor satisfies Eq. (3.5), and has the desired symmetry properties as well. So (3.6) and (3.8), as well as the inner product (3.7), are indeed a realization of the Nambu 3-algebra. In this realization, we must use the metric  $g_{ab}$  and its inverse  $g^{bc}$  to lower and raise indices, respectively. Plugging (3.10) into Eq. (A8) and (A9) gives the  $\mathcal{N} = 8$  BLG theory with  $SO(4)$  gauge group. The matter fields are in the vector representation of  $SO(4)$ . The  $\mathcal{N} = 8$ ,  $SO(4)$  theory has been conjectured to be the dual gauge theory of two M2-branes [4].

Comparing with the original  $\mathcal{N} = 8$  BLG theory in Ref. [1,2], our theory has a diffeomorphism invariance and a local  $SO(4)$  symmetry related to the 4D (internal) symmetric space. Specifically, the theory is invariant under the transformations

$$\begin{aligned} Z^A(\sigma') &= \frac{\partial \sigma^b}{\partial \sigma'^a} Z_b^A(\sigma), & \psi'_{Aa}(\sigma') &= \frac{\partial \sigma^b}{\partial \sigma'^a} \psi_{Ab}(\sigma), \\ A_{\mu b}^a(\sigma') &= \frac{\partial \sigma'^a}{\partial \sigma^c} \frac{\partial \sigma^d}{\partial \sigma'^b} A_{\mu d}^c(\sigma), \\ g'_{ab}(\sigma') &= \frac{\partial \sigma^c}{\partial \sigma'^a} \frac{\partial \sigma^d}{\partial \sigma'^b} g_{cd}(\sigma), \\ f'_{abcd}(\sigma') &= \tilde{R}'_{abcd}(\sigma') \\ &= \frac{\partial \sigma^e}{\partial \sigma'^a} \frac{\partial \sigma^f}{\partial \sigma'^b} \frac{\partial \sigma^g}{\partial \sigma'^c} \frac{\partial \sigma^h}{\partial \sigma'^d} \tilde{R}_{efgh}(\sigma) \\ &= \sqrt{g'} \varepsilon_{abcd}. \end{aligned} \quad (3.13)$$

where  $\sigma^a$  and  $\sigma'^a$  are two sets of coordinates of the 4D internal space. The  $\mathcal{N} = 8$  action is also invariant under the local  $SO(4)$  transformations:

$$\begin{aligned} \hat{Z}_i^A(\sigma) &= L_i^j(\sigma) Z_j^A(\sigma), \\ \hat{\psi}_{Ai}(\sigma) &= L_i^j(\sigma) \psi_{Aj}(\sigma), \\ \hat{A}_{\mu j}^i(\sigma) &= L_i^k(\sigma) L_j^l(\sigma) A_{\mu l}^k(\sigma) \\ L_i^k(\sigma) L_j^l(\sigma) \delta_{kl} &= \delta_{ij}, \\ \hat{f}_{ijkl}(\sigma) &= \hat{R}_{ijkl}(\sigma) = \varepsilon_{ijkl} = \tilde{R}_{ijkl}(\sigma), \end{aligned} \quad (3.14)$$

where  $Z_i^A = e_i^a Z_a^A$ ,  $\psi_{Ai} = e_i^a \psi_{Aa}$  and  $A_{\mu j}^i = e_j^b e_b^a A_{\mu a}^i$ , and  $L_i^j(\sigma) = \delta_{ik} \delta^{jl} L_k^j(\sigma)$ . Hence our theory is sort of generalized  $\mathcal{N} = 8$  BLG theory.

## APPENDIX A: A REVIEW THE $\mathcal{N} = 4, 5, 8$ THEORIES

In this section, we review the  $\mathcal{N} = 4, 5, 8$  CSM theories.

### 1. $\mathcal{N} = 4$ GW Theory

The  $\mathcal{N} = 4$  GW theory was first constructed in Ref. [3], using an ordinary Lie algebra approach. In Ref. [12], the  $\mathcal{N} = 4$  GW theory was constructed in terms of the symplectic 3-algebra. (The symplectic 3-algebra is reviewed in Sec. II A.) The action reads

$$\begin{aligned} \mathcal{L} &= \frac{1}{2} (-D_{\mu} \bar{Z}_a^{\alpha} D^{\mu} Z_a^{\alpha} + i \bar{\psi}_a^{\dot{\alpha}} \gamma^{\mu} D_{\mu} \psi_a^{\alpha}) \\ &\quad - \frac{i}{2} f_{abcd} Z_a^{\alpha} Z^{\alpha b} \psi_{\beta}^c \psi^{\beta d} \\ &\quad + \frac{1}{2} \epsilon^{\mu\nu\lambda} \left( f_{abcd} A_{\mu}^{ab} \partial_{\nu} A_{\lambda}^{cd} + \frac{2}{3} f_{abc}{}^g f_{gdef} A_{\mu}^{ab} A_{\nu}^{cd} A_{\lambda}^{ef} \right) \\ &\quad + \frac{1}{12} f_{abcg} f_{def}^g Z^{\alpha a} Z_{\beta}^b Z^{\beta(c} Z_{\gamma}^{d)} Z^{\gamma e} Z_{\alpha}^f. \end{aligned} \quad (A1)$$

Here  $\alpha = 1, 2$  and  $\dot{\alpha} = 1, 2$  are the undotted and dotted indices of the  $SU(2) \times SU(2)$  R-symmetry group, respectively;  $a = 1, \dots, 2n$  a symplectic 3-algebra index. The covariant derivative is defined as

$$D_{\mu} Z_d^{\alpha} = \partial_{\mu} Z_d^{\alpha} - \tilde{A}_{\mu}{}^c{}_d Z_c^{\alpha}, \quad \tilde{A}_{\mu}{}^c{}_d = A_{\mu}^{ab} f_{ab}{}^c{}_d. \quad (A2)$$

The matter fields obey the natural reality conditions  $\bar{Z}_a^{\alpha} = \omega_{ab} \epsilon^{\alpha\beta} Z_b^{\beta}$ , and  $\bar{\psi}_a^{\dot{\alpha}} = \omega_{ab} \epsilon^{\dot{\alpha}\beta} \psi_b^{\beta}$ . Here  $\epsilon^{\alpha\beta}$  and  $\epsilon^{\dot{\alpha}\beta}$  are invariant antisymmetric tensors of the R-symmetry group  $SU(2) \times SU(2)$ , satisfying  $\epsilon^{\alpha\beta} \epsilon_{\beta\gamma} = \delta_{\gamma}^{\alpha}$  and  $\epsilon^{\dot{\alpha}\beta} \epsilon_{\beta\gamma} = \delta_{\gamma}^{\dot{\alpha}}$ . The supersymmetry transformations are given by

$$\delta Z_\alpha^a = i\epsilon_\alpha^{\dot{a}} \psi_{\dot{a}}^a, \quad \delta \psi_{\dot{a}}^a = -\gamma^\mu D_\mu Z_\beta^a \epsilon_\alpha^{\dagger\beta} - \frac{1}{3} f_{bcd}^a Z_\beta^b Z_\gamma^c Z_\alpha^{\dagger\gamma}, \quad \delta \tilde{A}_\mu^c = i\epsilon^{\alpha\beta} \gamma_\mu \psi_\beta^b Z_\alpha^a f_{ab}^c, \quad (\text{A3})$$

where the parameter satisfies the reality condition

$$\epsilon_\alpha^{\dagger\beta} = -\epsilon^{\beta\gamma} \epsilon_{\dot{\alpha}\beta} \epsilon_\gamma^{\dot{\beta}}. \quad (\text{A4})$$

## 2. $\mathcal{N} = 5$ Theory

The  $\mathcal{N} = 5$  action reads [11]

$$\begin{aligned} \mathcal{L} = & \frac{1}{2} (-D_\mu \bar{Z}_a^\alpha D^\mu Z_\alpha^a + i\bar{\psi}_a^\alpha D_\mu \gamma^\mu \psi_\alpha^a) - \frac{i}{2} \omega^{\alpha\beta} \omega^{\gamma\delta} \omega_{def}{}^e (Z_\alpha^a Z_\beta^c \bar{\psi}_\gamma^b \psi_\delta^d - 2Z_\alpha^a Z_\delta^c \bar{\psi}_\gamma^b \psi_\beta^d) \\ & + \frac{1}{2} \epsilon^{\mu\nu\lambda} (\omega_{def}{}^e A_\mu^{ab} \partial_\nu A_\lambda^{cd} + \frac{2}{3} \omega_{fgh}{}^g f_{gde}{}^h A_\mu^{ab} A_\nu^{cd} A_\lambda^{ef}) \\ & - \frac{1}{60} (2f_{abc}{}^g f_{gdf}{}^e - 9f_{cda}{}^g f_{gfb}{}^e + 2f_{abd}{}^g f_{gcf}{}^e) Z_\alpha^f Z_\alpha^a Z_\beta^b Z_\beta^c Z_\gamma^d Z_\gamma^e. \end{aligned} \quad (\text{A5})$$

Here  $\alpha = 1, \dots, 4$  is a fundamental index of the  $Sp(4)$  R-symmetry group;<sup>6</sup>  $a = 1, \dots, 2n$  a symplectic 3-algebra index. The covariant derivative is defined as  $D_\mu Z_a^\alpha = \partial_\mu Z_a^\alpha - \tilde{A}_\mu^c Z_a^\alpha$ , where  $\tilde{A}_\mu^c = A_\mu^{ab} f_{ab}^c$ . The matter fields obey the reality conditions

$$Z_\alpha^{*a} = \omega^{\alpha\beta} \omega_{ab} Z_\beta^b, \quad \psi_\alpha^{*a} = \omega^{\alpha\beta} \omega_{ab} \psi_\beta^b. \quad (\text{A6})$$

Here  $\omega_{\alpha\beta}$  is the invariant antisymmetric tensor of  $Sp(4)$ , satisfying  $\omega_{\alpha\beta} \omega^{\beta\gamma} = \delta_\alpha^\gamma$ . The supersymmetry transformations are given by

$$\delta Z_\alpha^a = i\bar{\epsilon}_\alpha^{\dot{\beta}} \psi_{\dot{\beta}}^a, \quad \delta \psi_\alpha^a = \gamma^\mu D_\mu Z_\beta^a \epsilon_\alpha^{\dot{\beta}} + \frac{1}{3} f_{cdb}^a \omega^{\beta\gamma} Z_\beta^b Z_\gamma^c Z_\alpha^{\dot{\delta}} \epsilon_\alpha^{\dot{\delta}} - \frac{2}{3} f_{cdb}^a \omega^{\beta\delta} Z_\beta^b Z_\gamma^c Z_\alpha^{\dot{\delta}} \epsilon_\gamma^{\dot{\beta}}, \quad \delta \tilde{A}_\mu^c = i\bar{\epsilon}^{\alpha\beta} \gamma_\mu \psi_\beta^b Z_\alpha^a f_{ab}^c, \quad (\text{A7})$$

where the parameter  $\epsilon^{\alpha\beta}$  is antisymmetric in  $\alpha\beta$ , satisfying

$$\omega_{\alpha\beta} \epsilon^{\alpha\beta} = 0, \quad \epsilon_{\alpha\beta}^* = \omega^{\alpha\gamma} \omega^{\beta\delta} \epsilon_{\gamma\delta}.$$

## 3. $\mathcal{N} = 8$ BLG Theory

Here we will follow the convention of Ref. [15]. The action is given by

$$\begin{aligned} \mathcal{L} = & -D_\mu \bar{Z}_A^\alpha D^\mu Z_\alpha^A - i\bar{\psi}^{Aa} \gamma^\mu D_\mu \psi_{Aa} - i f_{cd}^{ab} \bar{\psi}^{Ad} \psi_{Aa} Z_B^b \bar{Z}_B^c + 2i f_{cd}^{ab} \bar{\psi}^{Ad} \psi_{Ba} Z_b^B \bar{Z}_A^c - \frac{i}{2} \epsilon_{ABCD} f_{cd}^{ab} \bar{\psi}^{Ac} \psi^{Bd} Z_a^C Z_b^D \\ & - \frac{i}{2} \epsilon^{ABCD} f_{cd}^{ab} \bar{\psi}_{Ac} \psi_{Bd} \bar{Z}_C^a \bar{Z}_D^b + \frac{1}{2} \epsilon^{\mu\nu\lambda} \left( f_{cd}^{ab} A_\mu^c \partial_\nu A_\lambda^d + \frac{2}{3} f_{dgc}^{ac} f_{gfb}^e A_\mu^b A_\nu^d A_\lambda^e \right) \\ & - \frac{2}{3} \left( f_{cd}^{ab} f_{fg}^{ed} - \frac{1}{2} f_{cd}^{eb} f_{fg}^{ad} \right) \bar{Z}_A^c Z_\alpha^A \bar{Z}_B^f Z_\alpha^B \bar{Z}_D^g Z_b^D. \end{aligned} \quad (\text{A8})$$

Here  $A = 1, \dots, 4$  is a fundamental index of the  $SU(4)$  R-symmetry group.<sup>7</sup> And  $a = 1, \dots, L$  is a Hermitian 3-algebra index. The covariant derivative is defined as  $D_\mu Z_b^A = \partial_\mu Z_b^A - \tilde{A}_\mu^a Z_b^A$ , where  $\tilde{A}_\mu^a = A_\mu^{cd} f_{cd}^a$ . The SUSY transformation law reads

$$\begin{aligned} \delta Z_\alpha^A &= -i\bar{\epsilon}^{AB} \psi_{B\alpha}, \quad \delta \psi_{B\alpha} = \gamma^\mu D_\mu Z_\alpha^A \epsilon_{AB} + f_{cd}^{ab} Z_\alpha^C Z_b^D \bar{Z}_C^c \epsilon_{AB} + f_{cd}^{ab} Z_\alpha^C Z_b^D \bar{Z}_B^c \epsilon_{CD}, \\ \delta \tilde{A}_\mu^c &= -i\bar{\epsilon}_{AB} \gamma_\mu Z_\alpha^A \psi^{Bb} f_{bd}^c + i\bar{\epsilon}^{AB} \gamma_\mu \bar{Z}_\alpha^A \psi_{Bb} f_{ad}^c. \end{aligned} \quad (\text{A9})$$

<sup>6</sup>In the  $\mathcal{N} = 4$  theory (see Appendix A1),  $\alpha = 1, 2$  transforms in the fundamental representation of one factor of the  $SU(2) \times SU(2)$  R-symmetry group. We hope this will not cause any confusion.

<sup>7</sup>In Sec. II B,  $A = 1, 2$  denotes the  $Sp(2)$  index of the curvature tensor of the quaternionic-Kähler manifold; in this section,  $A = 1, \dots, 4$  refers to the fundamental index of the  $SU(4)$  R-symmetry of the BLG theory. We hope this will not cause any confusion.

Here the SUSY transformation parameters  $\epsilon_{AB}$  satisfy

$$\epsilon_{AB} = -\epsilon_{BA}, \quad \epsilon_{AB}^* = \epsilon^{AB} = \frac{1}{2} \epsilon^{ABCD} \epsilon_{CD}. \quad (\text{A10})$$

In the action and the supersymmetry transformation law, only  $SU(4)$  R-symmetry is manifest. However, in Ref. [14], it was demonstrated explicitly that theory actually has an  $\mathcal{N} = 8$  R-symmetry, if the structure constants  $f^{abcd}$  are totally antisymmetric or the Hermitian 3-algebra becomes the Nambu 3-algebra.

## APPENDIX B: CONVENTIONS

In 1 + 2 dimensions, the gamma matrices are defined as

$$(\gamma_\mu)_\alpha^\gamma (\gamma_\nu)_\gamma^\beta + (\gamma_\nu)_\alpha^\gamma (\gamma_\mu)_\gamma^\beta = 2\eta_{\mu\nu} \delta_\alpha^\beta. \quad (\text{B1})$$

For the metric we use the  $(-, +, +)$  convention. We also define the totally antisymmetric tensor  $\epsilon^{\mu\nu\lambda} = -\epsilon_{\mu\nu\lambda}$ . So  $\epsilon_{\mu\nu\lambda} \epsilon^{\rho\nu\lambda} = -2\delta_\mu^\rho$ . We raise and lower spinor indices with an antisymmetric matrix  $\epsilon_{\alpha\beta} = -\epsilon^{\alpha\beta}$ , with  $\epsilon_{12} = -1$ . For example,  $\psi^\alpha = \epsilon^{\alpha\beta} \psi_\beta$  and  $\gamma_{\alpha\beta}^\mu = \epsilon_{\beta\gamma} (\gamma^\mu)_\alpha^\gamma$ , where  $\psi_\beta$  is a Majorana spinor. We use the following spinor summation convention:  $\psi \chi = \psi^\alpha \chi_\alpha$ ,  $\psi \gamma_\mu \chi = \psi^\alpha (\gamma_\mu)_\alpha^\beta \chi_\beta$ , where  $\psi$  and  $\chi$  are anticommuting Majorana spinors.
