Box 2735, Beijing 100190, China (Received 29 January 2015; published 13 May 2015)

In low-energy effective string theory and modified gravity theories, the propagating speed  $c<sub>T</sub>$  of primordial gravitational waves may deviate from unity. We find that the steplike variation of  $c_T$  during slow-roll inflation may result in an oscillating modulation to the B-mode polarization spectrum, which can hardly be imitated by adjusting other cosmological parameters, and the intensity of the modulation is determined by the dynamics of  $c<sub>T</sub>$ . Thus provided that the foreground contribution is under control, high-precision cosmic microwave background (CMB) polarization observations will be able to put tight constraint on the variation of  $c_T$ , and so the corresponding theories.

## I. INTRODUCTION

Inflation, as the paradigm of the early universe, has not only solved a lot of fine-tuning problems of the big bang theory, but also predicted the primordial scalar and tensor perturbations. The primordial tensor perturbations, i.e. primordial gravitational waves (GWs) [1–[3\],](#page-6-0) have arisen great attentions after the BICEP2 collaboration's announcement of the detection of B-mode signal in the CMB (around  $l \sim 80$ ) [\[4\]](#page-6-1), which was interpreted by them as the imprint of the primordial GWs, though this result is doubtful due to the foregrounds of polarized dust emissions [\[5,6\],](#page-6-2) see also [\[7\]](#page-6-3).

The detection of primordial GWs would verify general relativity (GR) and strengthen our confidence in inflation and quantum gravity [\[8\]](#page-6-4), and also put more constrains on inflation models and modified gravity at the same time. Besides the CMB experiments which mainly aimed at detecting low frequencies  $(10^{-17} - 10^{-15}$  Hz) GWs, many experiments relate to higher frequencies based on other methods, such as pulsar timing array  $(10^{-9} - 10^{-8} \text{ Hz})$ , laser interferometer detectors  $(10^{-4}-10^{4} \text{ Hz})$ , will be carried out in the coming decades. However, since the amplitude of the GWs would stay constant after they are stretched outside the horizon, and decrease with the expansion of the universe after they reenter the horizon, the primordial GWs with longer wavelength provide the most of opportunities for the detection [\[9\]](#page-6-5). Therefore, the CMB observations, especially the CMB B-mode detections, are still the most promising experiments to detect the primordial GWs if they actually exist.

Einstein's GR is the most accepted theory of gravity. However, it might be required to modify when dealing with the inflation in the primordial universe and the accelerated expansion of the current universe. During the matter and radiation dominated era, modified gravity has several effects on the CMB spectra, such as the lensing contribution to B-modes [\[10\]](#page-6-6) and the variation of propagating speed  $c<sub>T</sub>$  of primordial GWs [\[11,12\]](#page-6-7), we are especially interested in the latter in this paper, see e.g. [\[13\]](#page-6-8) for the case with the scalar perturbation. In GR, the graviton is massless and propagates along the null geodesics, so the propagating speed  $c<sub>T</sub>$  of GWs is naturally set to be unity, i.e. the speed of light. But in modified gravity, e.g., the low-energy effective string theory with high-order corrections [\[14](#page-6-9)–18], and also modified Gauss-Bonnet gravity [\[19\]](#page-6-10), and generalized Galileon (Horndeski theory [\[20\]\)](#page-6-11) [21–[24\],](#page-6-12) and beyond Horndeski theories [\[25,26\],](#page-6-13) and the effective theory of fluids at next-to-leading order in derivatives (e.g. [\[27\]](#page-6-14)),  $c_T$  might deviate from unity. Because the value of  $c_T$ determines the time of horizon crossing of GWs, during the recombination the change of  $c<sub>T</sub>$  can result in a shift of the peak position of the primordial B-modes, see [\[11,12\]](#page-6-7), for example.

In this paper, we focus on the effect of the variation of  $c<sub>T</sub>$ during slow-roll inflation on the CMB B-mode polarization, and show how it offers a distinct way to test the modified gravity theories. We find that the steplike variation of  $c_T$  may result in an oscillating modulation to the B-mode polarization spectrum, which can hardly be imitated by adjusting other cosmological parameters. The intensity of the modulation is determined by the ratio of  $c<sub>T</sub>$  before and after the variation, which depends on the dynamics of theoretical models. This oscillating modulation is so rich in feature that it may easily be discriminated from the variation of other parameters or other features. Thus provided that the foreground contribution is under control, high-precision CMB polarization observations will

<span id="page-0-0"></span>[<sup>\\*</sup>](#page-0-3) caiyong13@mails.ucas.ac.cn

<span id="page-0-1"></span>[<sup>†</sup>](#page-0-3) wangyutong12@mails.ucas.ac.cn

<span id="page-0-2"></span>[<sup>‡</sup>](#page-0-3) yspiao@ucas.ac.cn

be able to put tight constraint on the variation of  $c_T$ , and so the corresponding theories.

# II. OSCILLATING SPECTRUM OF PRIMORDIAL GWS

<span id="page-1-0"></span>We begin with the action for the GWs mode  $h_{ij}$ , e.g. [\[17,23\]](#page-6-15)

$$
S_{(2)} = \int d\tau d^3x \frac{a^2 Q_T}{8} \left[ h_{ij}^2 - c_T^2 (\vec{\nabla} h_{ij})^2 \right],\tag{1}
$$

where  $h_{ij}$  obeys  $\partial_i h_{ij} = 0$  and  $h_{ii} = 0$ ,  $Q_T$  is regarded as effective Planck scale  $M_{P, \text{eff}}^2(\tau)$ ,  $c_T$  is the propagating speed of primordial GWs, and the prime is the derivative with respect to the conformal time  $\tau$ ,  $d\tau = dt/a$ . During slowroll inflation, the slow-roll parameter  $\epsilon = -\dot{H}/H^2 \ll 1$ , as well as

$$
\epsilon_{Q} = \frac{\dot{Q}_{T}}{HQ_{T}} \ll 1, \qquad s = \frac{\dot{c}_{T}}{Hc_{T}} \ll 1 \tag{2}
$$

are required, e.g., see [\[28\]](#page-6-16) for a recent study.

Here, we will mainly focus on the effect of varying  $c_T$ , i.e., the condition  $s \ll 1$  might be broke at some point, on primordial GWs spectrum. Noting that the effects of varying sound speed of primordial scalar perturbations on the scalar power spectrum have been investigated in [\[29,30\]](#page-6-17). We do not get entangled with the details of  $(1)$  and the evolution of background, and will assume that the background is the slow-roll inflation, which is not affected by the variation of  $c_T$ , and set  $Q_T$  constant and  $M_P^2 = 1$ . We will discuss a possibility of such a case in the Appendix. In addition, there may be a mass term  $[31,32]$  in  $(1)$ , which might also be time-dependent [\[33\],](#page-6-19) but we will not involve it.

We can expand  $h_{ij}$  into Fourier series as  $h_{ij}(\tau, \mathbf{x}) =$  $\int \frac{d^3k}{(2\pi)^3} e^{-i\mathbf{k}\cdot\mathbf{x}} \hat{h}_{ij}(\tau, \mathbf{k})$ , where

$$
\hat{h}_{ij}(\tau, \mathbf{k}) = \sum_{\lambda = +,\times} [h_{\lambda}(\tau, k) a_{\lambda}(\mathbf{k}) + h_{\lambda}^*(\tau, -k) a_{\lambda}^{\dagger}(-\mathbf{k})] \epsilon_{ij}^{(\lambda)}(\mathbf{k}),
$$
\n(3)

<span id="page-1-1"></span>where the polarization tensors  $\epsilon_{ij}^{(\lambda)}(\mathbf{k})$  are defined by  $k_j \epsilon_{ij}^{(\lambda)}(\mathbf{k}) = 0$ ,  $\epsilon_{ii}^{(\lambda)}(\mathbf{k}) = 0$ , which satisfy  $\epsilon_{ij}^{(\lambda)}(\mathbf{k}) \epsilon_{ij}^{*(\lambda')}(\mathbf{k}) = 0$  $\delta_{\lambda\lambda'}$ ,  $\epsilon_{ij}^{*(\lambda)}(\mathbf{k}) = \epsilon_{ij}^{(\lambda)}(-\mathbf{k})$ , the commutation relation for the annihilation and creation operators  $a_\lambda(\mathbf{k})$  and  $a_\lambda^{\dagger}(\mathbf{k}')$  is  $[a_{\lambda}(\mathbf{k}), a_{\lambda}^{\dagger}(\mathbf{k}')] = \delta_{\lambda\lambda'}\delta^{(3)}(\mathbf{k} - \mathbf{k}').$  We define  $h_{\lambda}(\tau, k) =$  $u_k(\tau)/z_T$  and  $z_T = a\sqrt{Q_T}/2$ . Thus we get the equation of motion for  $u_k$  as

$$
u''_k + \left(c_T^2 k^2 - \frac{z''_T}{z_T}\right) u_k = 0.
$$
 (4)

To phenomenologically investigate the effect on primordial GWs spectrum induced by varying  $c_T$ , we assume that the variation of  $c_T$  can be described by a steplike function

$$
c_T = \begin{cases} c_{T1} & (\tau < \tau_0) \\ c_{T2} & (\tau > \tau_0), \end{cases}
$$
 (5)

where  $\tau_0$  < 0 is the transition time.

<span id="page-1-2"></span>We take the background evolution to be the slow-roll inflation. Of course, it is also provided that the sudden change of  $c_T$  will not affect the background evolution. Then, we have  $z_T''/z_T \equiv a''/a \approx (2 + 3\epsilon)/\tau^2$ , and the equation of motion [\(4\)](#page-1-1) becomes

$$
u_k'' + \left(c_T^2 k^2 - \frac{\nu^2 - 1/4}{\tau^2}\right) u_k = 0,\tag{6}
$$

<span id="page-1-3"></span>where  $\nu = \sqrt{\frac{9}{4} + 3\epsilon} \approx \frac{3}{2} + \epsilon$ . The solution to Eq. [\(6\)](#page-1-2) is familiar, we can write it as

$$
u_{k1} = \sqrt{-c_{T1}k\tau} [C_{1,1}H_{\nu}^{(1)}(-c_{T1}k\tau) + C_{1,2}H_{\nu}^{(2)}(-c_{T1}k\tau)],
$$
  
\n
$$
\tau < \tau_0,
$$
  
\n
$$
u_{k2} = \sqrt{-c_{T2}k\tau} [C_{2,1}H_{\nu}^{(1)}(-c_{T2}k\tau) + C_{2,2}H_{\nu}^{(2)}(-c_{T2}k\tau)],
$$
  
\n
$$
\tau > \tau_0,
$$
  
\n(7)

where  $H_{\nu}^{(1)}$  and  $H_{\nu}^{(2)}$  are the first and second kind Hankel functions of  $\nu$ th order, respectively. These coefficients  $C$ are functions of the comoving wave number  $k$ , but constants with respect to conformal time  $\tau$ . $C_{1,1}$  and  $C_{1,2}$  are determined by the initial condition.

<span id="page-1-4"></span>Here, we set the initial condition as the standard Bunch-Davies (BD) vacuum. Therefore, when  $c_{T1}k \gg \frac{a''}{a}$ , which corresponds to perturbations deep inside the horizon,

$$
u_k \sim \frac{1}{\sqrt{2c_{T1}k}} e^{-ic_{T1}k\tau}.
$$
 (8)

<span id="page-1-5"></span>When  $c_{T1}k \gg \frac{a''}{a}$ ,  $u_{k1}$  in Eq. [\(7\)](#page-1-3) should approximate to Eq. [\(8\).](#page-1-4) Allow for the Hankel function  $H_v^{(1)}(\xi) =$  $\sqrt{\frac{2}{\pi\xi}}e^{i(\xi-\frac{\nu\pi}{2}-\frac{\pi}{4})}$  and  $H_v^{(2)}(\xi) = \sqrt{\frac{2}{\pi\xi}}e^{-i(\xi-\frac{\nu\pi}{2}-\frac{\pi}{4})}$  when  $|\xi| \to \infty$ , we get

$$
C_{1,1} = \frac{\sqrt{\pi}}{2\sqrt{c_{T1}k}}, \qquad C_{1,2} = 0. \tag{9}
$$

The coefficients  $C_{2,1}$  and  $C_{2,2}$  are determined by requiring  $u_k$  and  $u'_k$  to be continuous at  $\tau = \tau_0$ , i.e. the matching condition. Then we obtain

OSCILLATING MODULATION TO B-MODE POLARIZATION … PHYSICAL REVIEW D 91, 103001 (2015)

$$
C_{2,1} = \frac{i\pi^{\frac{3}{2}}\tau_0 k^{\frac{1}{2}}}{16\sqrt{c_{T2}}} [c_{T1}(H_{-1+\nu}^{(1)}(-c_{T1}k\tau_0) - H_{1+\nu}^{(2)}(-c_{T1}k\tau_0))H_{\nu}^{(2)}(-c_{T2}k\tau_0) + c_{T2}(-H_{-1+\nu}^{(2)}(-c_{T2}k\tau_0))
$$
  
\n
$$
-H_{1+\nu}^{(2)}(-c_{T2}k\tau_0))H_{\nu}^{(1)}(-c_{T1}k\tau_0)],
$$
  
\n
$$
C_{2,2} = \frac{i\pi^{\frac{3}{2}}\tau_0 k^{\frac{1}{2}}}{16\sqrt{c_{T2}}} [c_{T1}(-H_{-1+\nu}^{(1)}(-c_{T1}k\tau_0) + H_{1+\nu}^{(1)}(-c_{T1}k\tau_0))H_{\nu}^{(1)}(-c_{T2}k\tau_0)
$$
  
\n
$$
+ c_{T2}(H_{-1+\nu}^{(1)}(-c_{T2}k\tau_0) - H_{1+\nu}^{(1)}(-c_{T2}k\tau_0))H_{\nu}^{(1)}(-c_{T1}k\tau_0)].
$$
\n(10)

The spectrum of primordial GWs is defined by  $P_T =$  $(k^3/2\pi^2)\langle 0|\hat{h}_{ij}(\tau, -\mathbf{k})\hat{h}_{ij}(\tau, \mathbf{k})|0\rangle$  with  $\tau \to 0$ , which is only a function of comoving wave number  $k$ . After neglecting the slow-roll parameter, from Eq. [\(7\)](#page-1-3) with  $\nu = 3/2$ , we have

$$
|u_{k2}| = \frac{\sqrt{2}}{-c_{T2}k\tau\sqrt{\pi}}|C_{2,1} - C_{2,2}|.
$$
 (11)

<span id="page-2-0"></span>Therefore, we obtain the power spectrum of primordial GWs as

$$
P_T = \frac{k^3}{2\pi^2} \sum_{\lambda = +,\times} |h_\lambda(\tau, k)|^2 = P_T^{\text{inf}} \frac{4k}{Q_T \pi c_{T2}^2} |C_{2,1} - C_{2,2}|^2,
$$
\n(12)

<span id="page-2-2"></span>where

$$
P_T^{\text{inf}} = 2H_{\text{inf}}^2/\pi^2 \tag{13}
$$

is that of standard slow-roll inflation without modified gravity, i.e.  $Q_T = 1$  and  $c_{T1} = c_{T_2} = 1$ , and  $H_{\text{inf}}$  is the Hubble parameter during inflation, which sets the scale of inflation.

The effect of varying  $c_T$  is encoded in  $C_{2,1}$  and  $C_{2,2}$ . We set  $x = c_{T2}/c_{T1}$  and defined a new function

$$
f(k, k_0, x) = \frac{4c_{T1}k}{\pi x^2} |C_{2,1} - C_{2,2}|^2,
$$
 (14)

<span id="page-2-3"></span>where  $k_0 = -1/(c_{T1}x\tau_0)$ . Then, the GWs spectrum [\(12\)](#page-2-0) may be rewritten as

$$
P_T = P_T^{\text{inf}} \cdot \frac{f(k, k_0, x)}{c_{T_1}^3 Q_T},\tag{15}
$$

where  $f(k, k_0, x)$  is obtained as

$$
f(k, k_0, x) = \frac{1}{x^2} \sin^2\left(\frac{k}{k_0}\right) + \frac{1}{x^4} \left[ \cos\left(\frac{k}{k_0}\right) - (1 - x^2) \frac{k_0}{k} \sin\left(\frac{k}{k_0}\right) \right]^2.
$$
\n(16)

We plot  $f(k, k_0, x)$  with respect to  $k/k_0$  in Fig. [1](#page-2-1), in which we set  $x = 0.9$  on the left panel and  $x = 1.1$  on the right panel, respectively. Here, the transition time  $\tau_0 =$  $-1/(c_T_1xk_0)$  sets a character scale  $1/k_0$ . When  $k \ll k_0$ , i.e. the perturbation mode has longer wavelength than  $1/k_0$ , we have  $f(k, k_0, x) \approx 1$ , and  $P_T = P_T^{\text{inf}}/(c_{T1}^3 Q_T)$  is scale invariant, which is the result of slow-roll inflation with almost constant  $c_T$  and  $Q_T$  [\[23,34\].](#page-6-20) When  $k \gg k_0$ , we have

<span id="page-2-1"></span>

FIG. 1 (color online). The function  $f(k, k_0, x)$ , where  $x = c_{T2}/c_{T1}$ . We have set  $x = 0.9$  on the left panel and  $x = 1.1$  on the right panel, respectively.

YONG CAI, YU-TONG WANG, AND YUN-SONG PIAO PHYSICAL REVIEW D 91, 103001 (2015)

$$
f(k, k_0, x) \approx \frac{1}{x^2} \left[ 1 + \left( \frac{1}{x^2} - 1 \right) \cos^2 \left( \frac{k}{k_0} \right) \right],
$$
 (17)

thus  $f(k, k_0, x)$  oscillates between  $1/x^2$  and  $1/x^4$ , and  $P_T$ oscillates correspondingly, just as we can see from Fig. [1](#page-2-1).

In the case of varying sound speed  $c_S$  of primordial scalar perturbations, the sudden change of  $c_s$  may lead to the oscillating modulation to the primordial scalar spectrum, as well as the CMB TT-mode spectrum, just as found in [\[29\]](#page-6-17). In addition, the oscillation in the primordial scalar spectrum can also be attributed to some other effects, such as inflaton potential with a small oscillation [\[35,36\],](#page-6-21) a sudden change in inflaton potential or its derivative, e.g., [\[37](#page-6-22)–40]. Thus the oscillation in the primordial scalar spectrum may be implemented without modified gravity, as has been mentioned.

However, the oscillation in the primordial GWs spectrum can only be attributed to the modified gravity. When the gravity is GR,  $P_T$  equals to  $P_T^{\text{inf}}$ , which is given in Eq. [\(13\)](#page-2-2). The oscillation of  $P_T^{\text{inf}}$  certainly requires  $H_{\text{inf}}$  is oscillating, which is impossible, unless the null energy condition is violated periodically. Though the particle production may also modify the GWs spectrum [\[41](#page-7-0)–43], it only leads to a bumplike contribution, which is entirely different from the behavior of oscillation.

# III. CMB B-MODE POLARIZATION SPECTRUM

The primordial GWs is imprint in CMB as the B-mode polarization. Thus the oscillation in the primordial GWs spectrum will inevitably affect the B-mode polarization spectrum.

To see such effects, we plot the CMB BB and TT-mode correlations in Fig. [2](#page-3-0), in which  $P_T^{\text{inf}}$  in [\(15\)](#page-2-3) is parametrized as

$$
P_T^{\text{inf}} = r A_R^{\text{inf}} \left( \frac{k}{k_*} \right)^{n_T^{\text{inf}}}.
$$
 (18)

Here, we assume that the scalar spectrum is hardly affected by the modified gravity, which will be clarified in the Appendix. Thus the scalar perturbation spectrum is set as  $P_{\mathcal{R}}^{\text{inf}} = A_{\mathcal{R}}^{\text{inf}}(k/k_*)^{n_{\mathcal{R}}^{\text{inf}}-1}$ , in which  $A_{\mathcal{R}}^{\text{inf}}$  is the amplitude of the scalar perturbations. In addition, we also assume that after inflation the propagating speed  $c<sub>T</sub>$  is unity, so that the spectrum of B-mode polarization is not affected by relevant evolution at late time, or see [\[11,12\]](#page-6-7).

<span id="page-3-1"></span>In the left panels of Fig. [2](#page-3-0), we see some obvious enhancements or suppressions to the reionization bump in the BB-mode spectrum, which depend on the oscillating effect on corresponding scales. The height of the reionization bump can be estimated roughly as [\[44\],](#page-7-1)

<span id="page-3-0"></span>

FIG. 2 (color online). Theoretical CMB BB and TT-mode power spectra for our oscillating GWs spectrum [\(15\)](#page-2-3) (brown line in the left panel and red solid line in the right panel) and the power-law GWs spectrum for reference (blue dashed line in the left panel and green dashed line in the right panel). The insets of the right panels are the TT-mode spectra for our oscillating GWs spectrum (the yellow solid lines) and the power-law GWs spectrum (the blue dashed lines) for reference. We set  $r = 0.05$  and  $k_0 = 1/30000 \text{ Mpc}^{-1}$ .

<span id="page-4-0"></span>

FIG. 3 (color online). BB-mode spectra at low multipoles for our oscillating GWs spectrum  $(15)$  with different x (solid lines) and the power-law GWs spectrum with different  $\tau_{ri}$  (dashed lines).

$$
C_{T,l\sim2}^{BB} \approx \frac{1}{100} (1 - e^{-\tau_{\rm ri}})^2 C_{T,l\sim2}^{TT},\tag{19}
$$

where  $C_{T,l}^{TT}$  stands for the TT-mode spectrum from the primordial GWs without the reionization and  $\tau_{\rm{ri}}$  is the optical depth to the beginning of reionization. The periodic enhancements and suppressions of the reionization bump are a reflection of the oscillations of primordial GWs spectrum on large scales. In addition, we can also see some obvious oscillations around the recombination peak at  $l \sim 80$ .

In the right panels of Fig. [2](#page-3-0), we see that the TT-mode spectrum is hardly affected by the oscillating primordial GWs power spectrum, since the contribution of GWs to TT-mode spectrum is negligible, compared with the scalar perturbations. The case of EE-mode polarization spectrum is actually also similar. Thus the main effect of varying speed of primordial GWs is on the B-mode polarization, which makes the B-mode polarization spectrum show its obvious enhancements or suppressions to the reionization bump and oscillations around the recombination peak.

In Ref. [\[45\],](#page-7-2) the authors have pointed out that it is possible to set to one the propagating speed of GWs by a proper redefinition of the metric. They got the gravitational waves spectrum in their Eq. (12) "same" as the standard one in the form. However, since they have made a redefinition of the time coordinate and the scale factor in Eq. [\(9\),](#page-1-5) the variation of their H with respect to  $\tilde{t}$  after redefinition is not the same as the variation of  $H$  with respect to t. Therefore, the oscillating feature induced by a steplike  $c_T$  is encoded in  $\hat{H}$ , the result in both frame should be the same.

It might also be a concern whether such a B-mode polarization spectrum can be imitated by adjusting other cosmological parameters or not. In Eq. [\(19\),](#page-3-1) the optical depth  $\tau_{ri}$  is relevant with the height of the reionization bump. We show the BB-mode spectrum with different  $\tau_{\text{ri}}$ in Fig. [3.](#page-4-0) We see that the change of  $\tau_{ri}$  can only alter the overall amplitude of the BB-mode spectrum at low multipoles, but hardly create the oscillation. In addition, in inflationary models with preinflation era, the reionization bump could also be suppressed (e.g. [46–[49\]\)](#page-7-3) or enhanced (e.g. [\[50\]](#page-7-4)). However, similarly, these models also only alter the overall amplitude of the BB-mode spectrum, without oscillation, at low multipoles. These results indicate that although the BB-mode spectrum may be modified by other ways, the oscillating modulation leaded by varying the speed of primordial GWs is difficult to be imitated. Thus the measure of B-mode polarization spectrum provides an appropriate way for testing the corresponding gravity physics in the primordial universe.

#### IV. DISCUSSION

In low-energy effective string theory and modified gravity theories, the propagating speed  $c<sub>T</sub>$  of primordial GWs may deviate from unity. We calculated the spectrum of primordial GWs, assuming that  $c<sub>T</sub>$  has a steplike variation and the background of slow-roll inflation is not affected by it. We found the spectrum of primordial GWs acquires an oscillating modulation, which makes the B-mode polarization spectrum show its obvious enhancements or suppressions to the reionization bump and oscillations around the recombination peak. The intensity of the modulation is determined by  $c_{T2}/c_{T1}$ . The frequency of the modulation is determined by  $k_0 = -1/(c_{T2}\tau_0)$ . Both depend on the dynamics of theoretical models.

The oscillating behavior of the B-mode polarization can only be attributed to the effect of modified gravity, since it can hardly be imitated by adjusting other cosmological parameters. The oscillating behavior is so rich in feature that it may be easily discriminated from the variation of other parameters or other features, thus the upcoming CMB experiments, such as CMBPol, B-Pol, will be able to put a tight constraint on the propagating speed of primordial GWs, and so the corresponding theories, provided that the foreground contribution is under control. In a certain sense, our paper again highlights the significance of B-mode polarization measures in exploring the fundamental physics of primordial universe.

Here, we only postulate a simple steplike variation of  $c_T$ , which, however, might be far complicated in some modified gravity models, as well as accompanied by the variation of  $Q_T$ . The effect could be nontrivial in more general cases, which is under study. But in a certain sense, a smooth change of  $c<sub>T</sub>$  will induce oscillations too, see e.g. [\[51\]](#page-7-5) for the case of scalar perturbations, so we expect that the case of GWs is similar. When we focus on the B-mode polarization spectrum, the assumption we adopted is that after inflation the propagating speed  $c<sub>T</sub>$  is unity, which may also be relaxed. Moreover, it may well be possible to

<span id="page-5-1"></span>

FIG. 4 (color online). The variation of  $\varphi$  and  $c_T^2$  with respect to cosmological time t in the case of  $x = c_{T2}/c_{T1} = 10$ , i.e.,  $A = -0.9$ , where  $t = 0$  corresponds to  $\tau_0$ . We have set  $b_1 = 50$ ,  $b_2 = -50$ .

produce oscillatory features beyond the standard slow-roll background. The varying  $c_T$  and  $Q_T$  will also affect the non-Gaussianities of primordial perturbations. The relevant issues are open.

#### APPENDIX

In this Appendix, we will argue how to realize the change of  $c_T$  and the changeless of  $Q_T$  in [\(1\)](#page-1-0) in low-energy effective string theory and modified gravity theories.

<span id="page-5-0"></span>In low-energy effective action of string theory, the simplest extension of the lowest-order action is e.g. [\[17\]](#page-6-15)

$$
\mathcal{L}_{\text{correction}} \sim -\frac{\alpha' \lambda \xi(\varphi)}{2} (c_1 R_{GB}^2 + c_2 G^{\mu\nu} \partial_{\mu} \varphi \partial_{\nu} \varphi), \quad \text{(A1)}
$$

where  $G^{\mu\nu} = R^{\mu\nu} - g^{\mu\nu}R/2$ , and  $R_{GB}^2 = R_{\mu\nu\lambda\rho}R^{\mu\nu\lambda\rho} 4R_{\mu\nu}R^{\mu\nu} + R^2$  is the Gauss-Bonnet term,  $\alpha'$  is the inverse string tension,  $\lambda$  is a parameter allowing for different species of string theories,  $c_1$  and  $c_2$  are coefficients. We have neglected the terms with  $\Box \varphi$  and  $(\partial_{\mu} \varphi \partial^{\mu} \varphi)^2$ , since both do not contribute to GWs.

The introducing of  $(A1)$  will affect not only the GWs, but also the adiabatic scalar perturbations, of course, it is interesting to check its effect on the latter. However, for our purpose, we will regard  $\varphi$  as the spectator field, so that the effects of [\(A1\)](#page-5-0) on the background and the scalar perturbations are negligible.

The action for GWs is [\(1\),](#page-1-0) and [\[17\]](#page-6-15)

$$
Q_T = 1 - \frac{\alpha \lambda}{2} (8c_1 \dot{\xi} H_{\text{inf}} - c_2 \xi \dot{\varphi}^2),
$$
  

$$
c_T^2 = \frac{1}{Q_T} \left[ 1 - \frac{\alpha \lambda}{2} (c_2 \xi \dot{\varphi}^2 + 8c_1 \dot{\xi}) \right],
$$
 (A2)

see also Ref. [\[52\]](#page-7-6) for that with  $c_1 = 0$ . When  $8c_1 \dot{\xi} H_{\text{inf}} \equiv$  $c_2 \xi \dot{\varphi}^2$  is imposed,  $Q_T = 1$ . Then, we have

$$
c_T^2 = 1 - 4c_1 \alpha' \lambda (\dot{\xi} H_{\text{inf}} + \ddot{\xi}). \tag{A3}
$$

The steplike variation of  $c_T^2$  requires that  $\dot{\xi}H_{\text{inf}} + \ddot{\xi}$  has the step at  $\tau = \tau_0$ .

As an example, we will give a numerical result of the variation of  $c_T^2$  and  $\varphi$  with respect to cosmological time t in the case of  $x = c_{T2}/c_{T1} = 10$ . According to Refs. [\[14,17\]](#page-6-9), we adopt

$$
\xi(\varphi) = -e^{-\varphi},
$$
  $c_1 = -1,$   
\n $\alpha' = 1,$  and  $\lambda = -\frac{1}{8}$  (for Heterotic string). (A4)

We take the expression of  $\varphi(t)$  as

$$
\varphi(t) = t - \ln \left[ b_1 e^t + b_2 A - A e^t - \frac{A e^{t - t^2}}{\sqrt{\pi}} + A t e^t + A e^{\frac{1}{4}} \text{erf} \left( \frac{1}{2} - t \right) - A e^t (t - 1) \text{erf}(t) \right],
$$
\n(A5)

where  $A = -1 + 1/x$ , and  $\operatorname{erf}(t) = \frac{2}{\sqrt{\pi}} \int_0^t e^{-t^2} dt$  is the Gauss error function,  $b_1$  and  $b_2$  are some constants. We plot  $\varphi$  and  $c_T^2$  with respect to cosmological time t in Fig. [4](#page-5-1).

Of course, the variation of  $c_T^2$  could be more complicated than a steplike evolution, which would be harder to deal with. However, as it may,  $Q_T > 0$  and  $c_T^2 > 0$  should be required to avoid ghost and gradient instabilities.

The action  $(A1)$  is actually equivalent to a subclass of the Horndeski theory, see Ref. [\[23\]](#page-6-20), and so the analysis is also similar for the Horndeski theory.
