Comment on "Nature of Long-Range Order in Stripe-Forming Systems with Long-Range Repulsive Interactions"

In a recent Letter, Mendoza-Coto et al. [\[1\]](#page-0-0) presented a study focusing on the nature of phase transitions in twodimensional (2D) stripe-forming systems with competing short-range attractive and long-range $(1/r^{\alpha})$ repulsive interactions. In particular, they conclude that for dipolar interactions ($\alpha = 3$), the isotropic-nematic phase transition is in the Kosterlitz-Thouless (KT) universality class. The authors support their findings by mapping an effective Hamiltonian into models which behavior resembles the 2D XY model at low temperatures [\[2\],](#page-0-1) and a finite-size scaling analysis from Langevin simulations. However, the validity of their conclusion is hindered by the lack of numerical evidence due to the relative small lattice sizes [\[3\]](#page-1-0), and more generally because a nonuniversal behavior is expected for such 2D systems[\[4\].](#page-1-1) As we illustrate here, tiny lattice effects are enough to alter the transition scenario completely.

Below we present a comparative analysis between the microcanonical caloric curves $\beta(E)$ obtained for the 2D dipolar Ising model [\[5\],](#page-1-2) which displays an isotropicnematic transition, and the 2D XY model [\[6\],](#page-1-3) which shows a KT transition. The Hamiltonians $H_{\text{dip}}^{\text{2D}}$ and H_{XY}^{2D} are given in terms of the parameters δ and J as in [\[5,6\],](#page-1-2) respectively. We evaluate $\beta(E)$ via the statistical temperature-weighted histogram analysis method (ST-WHAM) [\[7\]](#page-1-4) from data produced by Monte Carlo simulations with cluster updates for the XY model and replica exchange method for the dipolar Ising model.

Figure [1](#page-0-2) clearly shows that caloric curves for the two models exhibit distinct behaviors. While there are two S-shaped curves in $\beta(E)$ for the dipolar Ising model, a monotonic decreasing behavior is observed for the XY model. The two S-shaped curves in Fig. [1\(a\)](#page-0-2) corresponds to two transitions that separates the isotropic phase (which is stable for $E/N \gtrsim$ -1.086 and temperatures $T > 1/\beta_{\text{IN}} \simeq 0.8$), the nematic phase (snapshot in the middle), and the striped phase (which is stable for $E/N \lesssim$ -1.187 and $T < 1/\beta_{\text{NS}} \simeq$ 0.767, and displays ground-state configurations with 18 stripes for $N = 72²$). The S-shaped curves in $\beta(E)$ are due to the presence of first-order phase transitions [\[8\]](#page-1-5). The results for the XY model in Fig. [1\(b\)](#page-0-2) shows the region near the KT transition at $T = 1/\beta_{\text{KT}} \approx 0.893$. Accordingly, there is no signal of S-shaped curves in $\beta(E)$ because the KT transition is an infinite order transition [\[6\]](#page-1-3).

In conclusion, our analysis indicates that the isotropicnematic transition in the dipolar Ising model is a first-order phase transition instead of a KT transition. By considering this example and the expected nonuniversality, we argue that both mapping and numerical results in [\[1\]](#page-0-0) are insufficient to determine the nature of isotropic-nematic transition in 2D systems with competing short-range and dipolar interactions.

FIG. 1. Caloric curves $\beta(E)$ vs energy per spin E/N . (a) dipolar Ising model for $\delta = 2$, where a nematic phase is observed [\[5\].](#page-1-2) Horizontal lines denote transition temperatures obtained by Maxwell's construction. From left to right: configurations in the striped, nematic, and isotropic phases, respectively. (b) XY model for $J = 1$ at the KT transition.

We thank Y. Levin for the clarifying discussions, F. C. Poderoso for helping us with the simulations of the 2D X model, and the support from CNPq (Brazil, Grant No. 165153/2014-8) and LCCA-USP.
