(Received 21 November 2021; revised 25 February 2022; accepted 21 March 2022; published 6 April 2022)

We construct a relativistic chiral nucleon-nucleon interaction up to the next-to-next-to-leading order in covariant baryon chiral perturbation theory. We show that a good description of the np phase shifts up to $T_{\text{lab}} = 200$ MeV and even higher can be achieved with a $\tilde{\chi}^2/\text{d.o.f.}$ less than 1. Both the next-to-leadingorder results and the next-to-next-to-leading-order results describe the phase shifts equally well up to $T_{\text{lab}} = 200$ MeV, but for higher energies, the latter behaves better, showing satisfactory convergence. The relativistic chiral potential provides the most essential inputs for relativistic *ab initio* studies of nuclear structure and reactions, which has been in need for almost two decades.

DOI: [10.1103/PhysRevLett.128.142002](https://doi.org/10.1103/PhysRevLett.128.142002)

The nucleon-nucleon (NN) interaction plays an essential role in our microscopic understanding of nuclear physics. Starting from the pioneering works of Weinberg [\[1](#page-4-1)–[3](#page-4-2)], chiral effective field theory (ChEFT) has been successfully applied to derive the NN interaction. Nowadays, the socalled chiral nuclear forces have been constructed up to the fifth order [[4](#page-4-3)–[6](#page-4-4)] and sixth order [\[7](#page-4-5)] and reached the level of the most refined phenomenological forces, such as Argonne V_{18} [\[8](#page-4-6)] and CD-Bonn [\[9\]](#page-4-7), and have become the *de facto* standard in *ab initio* nuclear structure and reaction studies [[10](#page-4-8)–[13](#page-4-9)].

Nonetheless, these forces are based on the nonrelativistic (NR) heavy baryon chiral perturbation theory (ChPT) and cannot be used in relativistic many-body studies [[14](#page-4-10)–[18](#page-4-11)], for which till now only the Bonn potential [\[19\]](#page-4-12) has been widely used [[20](#page-4-13)]. In addition, there are continuing discussions on the relevance of renormalization group invariance and how the Weinberg power counting should be modified to allow for proper nonperturbative renormalization group invariance [[21](#page-4-14)[,22\]](#page-4-15). Lorentz covariance, as one of the most fundamental requirements of nature, may play a role here. It is particularly inspiring to note that in the onebaryon sector, covariant baryon ChPT has been shown to provide new perspectives on a number of long-standing puzzles, such as baryon magnetic moments [[23](#page-4-16)], Compton scattering off protons [\[24\]](#page-4-17), pion-nucleon scattering [[25](#page-4-18)], and baryon masses [\[26](#page-4-19)[,27\]](#page-4-20). See Ref. [\[28\]](#page-4-21) for a short review.

Recently, a covariant power counting approach similar to the extended-on-mass-shell scheme in the one-baryon sector [[29](#page-4-22),[30](#page-4-23)] was proposed to describe the NN interaction [\[31](#page-4-24)[,32\]](#page-4-25). (We note that a modified Weinberg approach to the NN scattering problem was proposed in Ref. [\[33\]](#page-4-26), which employs time-ordered perturbation theory and relies on the manifestly Lorentz-invariant effective Lagrangian and aims to improve the UV behavior of Weinberg's approach [\[34](#page-4-27)– [36\]](#page-4-28).) At leading order (LO), the covariant scheme has been successfully tested in the NN system [[31](#page-4-24),[37](#page-4-29)–[40\]](#page-4-30), hyperon-nucleon system [\[41](#page-4-31)–[46\]](#page-4-32), and $\Lambda_c N$ system [[47](#page-4-33),[48](#page-4-34)]. In addition to providing already a reasonable description of the $J = 0, 1$ np phase shifts at LO, it also shows some interesting features of proper effective field theories. In Ref. [\[37](#page-4-29)], it was shown that for the ${}^{1}S_{0}$ partial wave, some of the typical low-energy features can be reproduced at LO, contrary to the conventional Weinberg approach. In addition, it also shows improved renormalization group invariance, for example, in the ${}^{3}P_0$ channel [\[40\]](#page-4-30). In Ref. [[49](#page-4-35)], it was shown in a hybrid phenomenological approach that the LO relativistic three-body interaction leads to a satisfactory description of polarized pd scattering data in the whole energy range below the deuteron breakup threshold, solving the long-standing A_v puzzle thanks to the new terms considered in the 3N force. Furthermore, in Ref. [[50](#page-4-36)], it was shown that the relativistic effects in the perturbative two-pion-exchange (TPE) contributions do improve the description of the peripheral NN scattering data compared to their nonrelativistic counterparts. In Ref. [\[51\]](#page-4-37), the same feature is found also for the nonperturbative TPE contributions.

Nonetheless, for realistic studies of nuclear structure and reactions, the relativistic chiral force has to be constructed

FIG. 1. Relativistic kinematics of nucleon-nucleon scattering.

to higher chiral orders. Furthermore, a complete understanding of the relativistic chiral nuclear force beyond leading order is also of high relevance. For such purposes, in the present work, we construct the first accurate relativistic NN interaction up to the next-to-next-toleading order (NNLO). (Recent studies show that the NNLO nonrelativistic chiral forces can provide reliable inputs already, but the $N³LO$ forces yield smaller uncertainties [[52](#page-4-38)]).

In order to take into account the nonperturbative nature of the NN interaction, we solve the following relativistic Blankenbecler-Sugar equation [[53](#page-4-39)],

$$
T(\boldsymbol{p}', \boldsymbol{p}, s) = V(\boldsymbol{p}', \boldsymbol{p}, s) + \int \frac{d^3 \boldsymbol{k}}{(2\pi)^3} V(\boldsymbol{p}', \boldsymbol{k}, s)
$$

$$
\times \frac{m^2}{E_k} \frac{1}{q_{\text{c.m.}}^2 - k^2 - ie} T(\boldsymbol{k}, \boldsymbol{p}, s), \qquad (1)
$$

where $|\boldsymbol{q}_{\text{c.m.}}| = \sqrt{s/4 - m^2}$ is the nucleon momentum on the mass shell in the center-of-mass (c.m.) frame, and a sharp cutoff Λ is introduced to regularize the potential and its value will be specified later. The momenta of the incoming, outgoing, and intermediate nucleons are depicted in Fig. [1,](#page-1-0) consistent with the 3D reduction of the Bethe-Salpeter equation to the Blankenbecler-Sugar equation [[54](#page-4-40)].

Up to NNLO, the relativistic chiral potential consists of the following terms,

$$
V = V_{\text{CT}}^{\text{LO}} + V_{\text{CT}}^{\text{NLO}} + V_{\text{OPE}} + V_{\text{TPE}}^{\text{NLO}} + V_{\text{TPE}}^{\text{NNLO}} - V_{\text{IOPE}},\qquad(2)
$$

in which the first two terms refer to the LO $[O(p^0)]$ and NLO $[O(p^2)]$ contact contributions, while the next three terms denote the one-pion exchange (OPE), leading, and subleading TPE contributions. The last term represents the iterated OPE contribution.

The chiral effective Lagrangians for the nucleon-nucleon interaction in covariant baryon ChPT have been constructed up to $\mathcal{O}(p^4)$ in Ref. [[32](#page-4-25)]. There are four contact terms at LO, 13 terms at NLO, and no contact terms at NNLO. As is argued in the Supplemental Material [\[55\]](#page-4-41), the large subleading TPE contributions affect the descriptions of some higher partial waves, especially ${}^{3}P_{2}$. Relevant discussions on the nonrelativistic cases can be found in Refs. [\[56](#page-4-42)–[58](#page-5-0)]. In order to partially compensate the large subleading TPE contributions to the ${}^{3}P_{2}$ channel, we promote two nominal $N³LO$ contact terms to NLO.

TABLE I. Decay constant f_{π} (in units of MeV) [\[11\]](#page-4-43), coupling constant g_A [[11](#page-4-43)], and NLO πN couplings (in units of GeV⁻¹) [\[60\]](#page-5-6) adopted for evaluating the OPE and TPE diagrams.

Considering that in our covariant power counting, the NLO contact terms already contain terms of $\mathcal{O}(p^4)$ as is depicted in the Supplemental Material [\[55\]](#page-4-41), we promote the same terms but originally counted as of $N³LO$ to NLO for the ${}^{3}P_{2}$ - ${}^{3}F_{2}$ partial waves. This is equivalent to removing part of the correlations between the higher order contact terms for ${}^{3}P_{2} {}^{3}F_{2}$ and the other $J = 2$ partial waves. Therefore, in the end, we have in total 19 low-energy constants (LECs) up to NNLO. We note that this number is larger than that of the nonrelativistic NNLO potential (9) but smaller than that of $N³LO$ (24) [\[58,](#page-5-0)[59\]](#page-5-1). (It should be noted that the two isospin-violating LECs are not included here. Furthermore, the results of Ref. [[59](#page-5-1)] with which we compare were obtained by setting $c_{2,3,4}$ semifree.) In our relativistic framework, the 19 LECs contribute to all the partial waves with total angular momentum $J \leq 2$, which makes it impossible to reorganize the LECs according to partial waves, different from the nonrelativistic cases. (Note that in the nonrelativistic framework, there is no LEC for the ${}^{3}F_2$ partial wave up to N³LO.) We refer to the Supplemental Material [\[55\]](#page-4-41) for the explicit expressions of the LO and NLO contact potentials.

For the treatment of nonperturbative OPE and TPE contributions, we refer to Ref. [\[51\]](#page-4-37). In Table [I,](#page-1-1) we show the values of the LECs needed to evaluate the OPE and TPE contributions.

An important feature of ChEFT is that it allows for reliable uncertainty quantification. In the literature, two different ways have been used to estimate the truncation uncertainties of chiral nuclear forces. One is varying the cutoff in a reasonable range, for example, from 450 to 550 MeV [\[11\]](#page-4-43). The other is to treat the difference between the optimal results obtained at different orders as the estimate of truncation uncertainties [[4](#page-4-3)]. Recently, a general Bayesian model has been proposed [\[61](#page-5-2)–[63](#page-5-3)] and applied in the latest nonrelativistic studies [[64](#page-5-4)–[66\]](#page-5-5), which we follow in the present work. This method is statistically well established and can provide a statistical interpretation for the estimated uncertainties. For a detailed account of the implementation of this approach in the present study, see the Supplemental Material [\[55\]](#page-4-41).

In Ref. [[51](#page-4-37)], we showed that the higher partial waves which do not receive contact contributions up to NNLO can be well described with a cutoff of 0.9 GeV. In addition, only the ${}^{3}D_3$ partial wave is sensitive to the cutoff, which implies that higher order LECs are needed for this particular partial wave to achieve renormalization group invariance. As a result, in the fitting of the LECs at NLO and NNLO, we fix the cutoff at 0.9 GeV.

FIG. 2. NN phase shifts for partial waves with $J \le 2$. The red solid lines denote the relativistic NNLO results obtained with a cutoff of $\Lambda = 0.9$ GeV, and the blue dashed lines denote the relativistic NLO results obtained with a smaller cutoff of $\Lambda = 0.6$ GeV. The corresponding bands represent the uncertainties for a DoB level of 68%. For comparison, we also show the LO relativistic results (black dotted lines) obtained with a cutoff of $\Lambda = 0.6$ GeV and the two sets of nonrelativistic N³LO results NR-N³LO Idaho ($\Lambda = 0.5$ GeV, green dash-dotted lines) [\[11,](#page-4-43)[59](#page-5-1)] and NR-N³LO EKM (cutoff $= 0.9$ fm, magenta short-dotted lines) [[4](#page-4-3),[73](#page-5-12)]. The black dots denote the PWA93 phase shifts [\[68\]](#page-5-8). The shaded regions denote that those data are not fitted, and the corresponding relativistic results are predictions.

Following the strategy adopted in nonrelativistic studies, e.g., Refs. [\[4,](#page-4-3)[67\]](#page-5-7), we perform a global fit to the np phase shifts for all the partial waves with total angular momentum $J \leq 2$ [[68](#page-5-8)]. (For a justification of direct fits to phase shifts, see Ref. [[69](#page-5-9)]. An alternative fit to the results of the Granada partial wave analysis [[70](#page-5-10)–[72\]](#page-5-11) is given in the Supplemental Material [\[55](#page-4-41)].) For each partial wave, we choose eight data points with laboratory kinetic energy $T_{\text{lab}} = 1, 5, 10, 25,$ 50, 100, 150, 200 MeV for the fitting. The χ^2 -like function to be minimized, $\tilde{\chi}^2$, is defined as

$$
\tilde{\chi}^2 = \sum_i (\delta^i - \delta^i_{\text{PWA93}})^2,\tag{3}
$$

where δ^i are theoretical phase shifts or mixing angles, and $\delta_{\rm PWA93}^{i}$ are their empirical PWA93 counterparts [[68](#page-5-8)]. A few

remarks are in order. First, the $\tilde{\chi}^2$ defined above does not have proper statistical meaning, as no uncertainties are assigned, and the number of data fitted are a bit arbitrary (eight for each partial wave in the present study). Second, as the same uncertainties for the phase shifts and mixing angle are assumed, this necessarily put more weight on those partial waves of large magnitude, for example, ${}^{1}S_{0}$ and ${}^{3}S_{1}$.

The so-obtained fitting results are shown in Fig. [2,](#page-2-0) where the theoretical uncertainties are obtained via the Bayesian model explained in the Supplemental Material [[55](#page-4-41)] for a Degree of Belief (DoB) level of 68%. The corresponding LECs are given in Table [II](#page-3-0). For comparison, we also show the nonrelativistic $N³LO$ results obtained with different strategies for regularizing chiral potentials from Refs. [\[11,](#page-4-43)[59\]](#page-5-1) and Refs. [[4](#page-4-3)[,73\]](#page-5-12), which are denoted as $NR-N³LO$ Idaho and $NR-N³LO$ EKM, respectively. Comparing the LO, NLO, and NNLO results as well as the uncertainties, it is clear that the chiral results are converging reasonably well. In addition, the LECs look quite natural, particularly those at NNLO, as the magnitude of most of them is between 1 and 10, though O_1 , O_{14} , O_{15} , and O_{16} are perhaps a little bit large, but not abnormally large.

First, we notice that the NLO and NNLO relativistic results describe the *np* phase shifts very well up to $T_{\text{lab}} = 200 \text{ MeV}$, at a level similar to the nonrelativistic N³LO results. Particularly interesting is that the NLO and the NNLO results also agree well with each other for $T_{\text{lab}} \leq 200$ MeV, while the NNLO results are in better agreement the PWA93 data for larger kinetic energies. This demonstrates that the chiral series converges well. On the other hand, for ${}^{3}F_2$, the NLO results are better, which can be attributed to the compromise that one has to make to fit all the $J = 2$ partial waves with five LECs to balance the large contributions of subleading TPE. It can be largely improved once the correlation between the D waves with $J = 2$ and ${}^{3}P_{2}$ - ${}^{3}F_{2}$ are removed; i.e., the D waves and ${}^{3}P_{2}$ - ${}^{3}F_{2}$ are fitted separately or the cutoff is slightly modified. We note that in obtaining the $NR-N³LO$ Idaho results, the phase shifts of this channel were lowered by a careful fine-tuning of c_2 and c_4 [\[59\]](#page-5-1).

The $\tilde{\chi}^2$'s for each partial wave are given in Table [III](#page-3-1). Judging from the total χ^2 , the quality of the relativistic fits is compatible to the nonrelativistic $N³LO$ results. Comparing the NR-N³LO EKM results with the relativistic NNLO results, we find that although the total $\tilde{\chi}^2$'s are similar, they originate from different partial waves. The largest contribution to the total $\tilde{\chi}^2$ of NR-N³LO EKM comes from the ${}^{1}S_{0}$ partial wave, while that of our NNLO results originates from the ${}^{3}D_2$ partial wave. It should also be noted that if we set the cutoff at 0.8 GeV, we can achieve a total $\tilde{\chi}^2$ as small as 5.3 (see the Supplemental Material [\[55\]](#page-4-41) for details), which is even smaller than that of $NR-N³LO$ Idaho, which is about 9. However, as shown in Ref. [[51](#page-4-37)], the ${}^{3}D_3$ partial wave cannot be well described with a cutoff of 0.8 GeV. Therefore, in the present work, we stick to the cutoff of 0.9 GeV [\[74\]](#page-5-13).

To summarize, we constructed a relativistic chiral nucleon-nucleon interaction up to the next-to-next-to-leading order in covariant baryon chiral perturbation theory. The 19 low-energy constants were fixed by fitting to all the partial wave phase shifts with total angular momentum $J \leq 2$. We obtained a good description of the PWA93 phase shifts. The next-to-leading-order and the next-to-next-toleading-order results agree well with each other for $T_{\text{lab}} \leq 200$ MeV, while at higher energies the NNLO results agree better with the PWA93 phase shifts. This demonstrated the convergence of the covariant chiral expansions. Given the quality already achieved in describing the np phase shifts, the NNLO relativistic chiral NN interaction provides the much wanted inputs for relativistic ab initio nuclear structure and reaction studies. In particular, it may provide new insights into many long-standing problems, e.g., the A_v puzzle, in combination with the leading order relativistic 3N chiral force explored in Ref. [[49](#page-4-35)], which appears at NNLO.

- [74] It should be mentioned that the relatively large cutoff together with the pion-nucleon couplings c_i determined from pion-nucleon scattering (which result in strongly attractive subleading TPE contributions in some channels) could lead to the appearance of deeply bound states (see Ref. [[5](#page-4-44)] for a detailed discussion). Although they are beyond the range of the EFT and are irrelevant for the low-energy physics [\[67,](#page-5-7)[75\]](#page-5-14), they could potentially complicate manybody calculations (see Ref. [[75](#page-5-14)] for a solution). We leave a study of their impact on relativistic *ab initio* calculations to a future work.
