 (Received 9 December 1997; revised manuscript received 13 February 1998)

A precise measurement of the ratio of Drell-Yan yields from an 800 GeV/c proton beam incident on hydrogen and deuterium targets is reported. Over 140 000 Drell-Yan muon pairs with dimuon mass $M_{\mu^+\mu^-} \ge 4.5 \text{ GeV}/c^2$ were recorded. From these data, the ratio of antidown (\bar{d}) to antiup (\bar{u}) quark distributions in the proton sea is determined over a wide range in Bjorken x. A strong x dependence is observed in the ratio \bar{d}/\bar{u} , showing substantial enhancement of \bar{d} with respect to \bar{u} for x < 0.2. This result is in fair agreement with recent parton distribution parametrizations of the sea. For x > 0.2, the observed \bar{d}/\bar{u} ratio is much nearer unity than given by the parametrizations. [S0031-9007(98)05905-5]

PACS numbers: 13.85.Qk, 14.20.Dh, 24.85.+p, 25.40.Ve

No known symmetry requires equality of the \bar{d} and \bar{u} distributions in the proton. Until recently it had been generally assumed that $\bar{d}(x) = \bar{u}(x)$ for lack of experimental evidence to the contrary. This assumption may be evaluated by use of the expression

$$\int_{0}^{1} [F_{2}^{p}(x) - F_{2}^{n}(x)] \frac{dx}{x} = \frac{1}{3} - \frac{2}{3} \int_{0}^{1} [\bar{d}_{p}(x) - \bar{u}_{p}(x)] dx.$$
(1)

Here $F_2^p(x)$ and $F_2^n(x)$ are the proton and neutron inelastic structure functions, and $\bar{d}_p(x)$ and $\bar{u}_p(x)$ are the antidown and antiup quark distributions in the proton sea as a function of Bjorken x. Equation (1) requires the assumption of charge symmetry between the proton and neutron (i.e., $u_p = d_n$, $\bar{u}_p = \bar{d}_n$, etc.). If the nucleon sea is flavor symmetric in the light quarks, the value of the integral on the left is 1/3, a result referred to as the Gottfried sum rule (GSR) [1]. In 1991 the New Muon Collaboration (NMC) at CERN presented evidence that the GSR is violated, based on deep inelastic muon scattering data from hydrogen (p) and deuterium (d). They reported a final value of $\int_0^1 [F_2^p(x) - F_2^n(x)] \frac{dx}{x} =$ 0.235 \pm 0.026 [2], which implies that

$$\int_0^1 \left[\bar{d}_p(x) - \bar{u}_p(x) \right] dx = 0.147 \pm 0.039, \quad (2)$$

a considerable excess of \bar{d}_p relative to \bar{u}_p . This result has been adopted in the most current parametrizations of the parton distributions in the nucleon [3,4].

Following publication of the NMC result, the use of the Drell-Yan process [5] was suggested [6] as a means by which the light antiquark content of the proton could be more directly probed. This was first done by the Fermilab E772 Collaboration. They compared the production of Drell-Yan muon pairs from isoscalar targets to that from a neutron rich target. This measurement sets constraints on the nonequality of \bar{u} and \bar{d} in the range $0.04 \le x \le 0.27$ [7]. Later, the CERN experiment NA51 [8] carried out a comparison of the Drell-Yan muon pair yield from hydrogen and deuterium at a single value of x using a 450 GeV/c proton beam and found

$$\frac{\bar{u}_p}{\bar{d}_p}\Big|_{\langle x \rangle = 0.18} = 0.51 \pm 0.04 \pm 0.05.$$
(3)

A recent review by Kumano [9] presents an extensive discussion of the existing literature on the flavor asymmetry of the antiquark sea. Fermilab Experiment 866 (E866) measured the Drell-Yan muon pair yield from 800 GeV/*c* proton bombardment of liquid deuterium and hydrogen targets. From these data, \bar{d}/\bar{u} and $\bar{d} - \bar{u}$ in the proton over the range 0.020 < x < 0.345 are extracted. A significant difference between the \bar{d} and \bar{u} distributions is found.

E866 used a 3-dipole magnet spectrometer [10] employed in previous experiments (E605, E772, and E789), modified by the addition of new drift chambers and hodoscopes with larger acceptance at the first tracking station. Other improvements to the spectrometer included a programmable trigger system [11] and a VME-based data acquisition system. An 800 GeV/c extracted proton beam with up to 2×10^{12} protons per 20 s spill bombarded one of three identical 50.8 cm long cylindrical target flasks containing either liquid hydrogen, liquid deuterium, or vacuum. After passing through the target, the remaining beam was intercepted by a copper beam dump located inside the second dipole magnet. The beam dump was followed by a 13.4 interaction length absorber wall of copper, carbon, and polyethylene which blocked the entire aperture of the magnet. This absorber wall removed hadrons produced in the target and the dump, ensuring that only muons traversed the spectrometer's detectors. The detection system consisted of four tracking stations and a momentum analyzing magnet. The spectrometer's acceptance as a function of p_T , the transverse momentum of the dimuon pair, was reasonable to 3.0 GeV/c, with some acceptance to 5.0 GeV/c.

The targets alternated between hydrogen and deuterium every five beam spills with a single spill collected on the empty flask at each target change. The targets were 3.54 and 8.14 g/cm² thick, corresponding to 7% and 15% of an interaction length for hydrogen and deuterium, respectively. Beam intensity was monitored by secondary-emission detectors, an ion chamber, and quarter-wave rf cavities. Two four-element scintillator telescopes viewing the targets at nearly 90° monitored the luminosity, beam duty factor, and data acquisition live time. The trigger required a pair of triple hodoscope coincidences having the topology of a muon pair from the target. Typically 70 triggers per second were recorded with an electronic live time above 98%. An integrated flux of 1.3×10^{17} protons was delivered.

Over 330 000 Drell-Yan events were recorded, using three different spectrometer settings which focused low, intermediate, and high mass muon pairs. The data collected with the low and intermediate mass settings have systematic effects of a few percent which require additional study. The data from the high mass setting are relatively free from these effects due to the greatly reduced rates in the tracking chambers. Therefore, this Letter presents only the results from the high mass setting, with over 140 000 Drell-Yan events.

In calculating the Drell-Yan yields, a small correction (averaging 0.2%) for random coincidences between two

unrelated, oppositely charged muons was made. This correction was evaluated by studying the observed rates of same charge muon pairs. A background rate of approximately 8% from the target flask and beam line windows was measured using the evacuated flask and was subtracted. Given the identical geometry of the deuterium and hydrogen targets and the slight difference in the average interaction point due to beam attenuation in the target, acceptance differences between the two targets were shown by a Monte Carlo simulation of the spectrometer to be very small. The measured cross section ratio was corrected for differences in beam attenuation in the targets, target density, and a small hydrogen contamination in the deuterium target. Additionally, the high luminosity caused a small, rate dependent inefficiency. This led to a correction of 1.2% in the cross section ratio. The systematic error in the ratio of yields from the two targets is dominated by the uncertainties in the rate dependence $(\pm 0.6\%)$, hydrogen contamination in the deuterium target $(\pm 0.2\%)$, and beam attenuation $(\pm 0.2\%)$. All other contributions, including the production of muon pairs from secondary hadron reinteraction, are small. The total systematic error in the cross section ratio is less than $\pm 1\%$.

The resulting ratio of the Drell-Yan cross section per nucleon for p + d to that for p + p is shown in Fig. 1 and Table I as a function of x_2 [12,13], the momentum fraction (Bjorken x) of the target quark in the parton model. (The Bjorken x of the beam parton is denoted by x_1 .) Muon pairs with mass $M_{\mu^+\mu^-}$ below 4.5 GeV/ c^2 or between 9.0 and 10.7 GeV/ c^2 were removed to eliminate

FIG. 1. The ratio $\sigma^{pd}/2\sigma^{pp}$ of Drell-Yan cross sections vs x_2 . Shown are next-to-leading order calculations, weighted by acceptance, of the Drell-Yan cross section ratio using the CTEQ4M (solid line) and MRS(R2) (dashed line) parton distributions. Also shown is a *leading order* calculation of the cross section ratio using CTEQ4M (dotted line). In the lower CTEQ4M curve $\overline{d} - \overline{u}$ has been set to 0 as described in the text. The errors are statistical only. An additional 1% systematic uncertainty is common to all points.

TABLE I. Ratio of deuterium to hydrogen cross sections per nucleon vs x_2 . The average of the kinematic variables for each bin is also tabulated. Note that $\langle x_1 \rangle = \langle x_F \rangle + \langle x_2 \rangle$. The errors are statistical only. An additional 1% systematic uncertainty is common to all points.

$\langle x_2 \rangle$	$\langle x_{\rm F} \rangle$	$\langle p_T \rangle$ (GeV/c)	$\langle M_{\mu^+\mu^-} angle \ ({ m GeV}/c^2)$	$\sigma^{pd}/2\sigma^{pp}$

contributions from the J/ψ and Y resonance families. The data clearly show that the Drell-Yan cross section per nucleon for p + d exceeds p + p over an appreciable range in x_2 . Figure 1 also shows the predictions for next-to-leading order calculations [14] of the cross section ratio, weighted by the E866 spectrometer's acceptance, using the CTEQ4M [3] and MRS(R2) [4] parton distributions. The lower curve shows the predicted ratio for a modified CTEQ4M parton distribution which maintains the parametrization for $\bar{d}_p + \bar{u}_p$ but sets $\bar{d}_p - \bar{u}_p = 0$. The data are in reasonable agreement with the unmodified CTEQ4M and the MRS(R2) predictions for $x_2 < 0.15$. It is clear that $\bar{d}_p \neq \bar{u}_p$ in this range. Above $x_2 = 0.15$ the data lie well below both parametrizations.

The acceptance of the spectrometer was largest for $x_F = x_1 - x_2 > 0$. In this kinematic regime the Drell-Yan cross section is dominated by the annihilation of a beam quark with a target antiquark. This fact, coupled with the assumption of charge symmetry between the neutron and proton and the assumption that the deuteron parton distributions can be expressed as the sum of the proton and neutron distributions, yields a simple approximate form of the Drell-Yan cross section ratio,

$$\frac{\sigma^{pd}}{2\sigma^{pp}}\Big|_{x_1 \gg x_2} \approx \frac{1}{2} \frac{(1 + \frac{1}{4}\frac{d_1}{u_1})}{(1 + \frac{1}{4}\frac{d_1}{u_1}\frac{\bar{d}_2}{\bar{u}_2})} \left(1 + \frac{\bar{d}_2}{\bar{u}_2}\right).$$
(4)

The subscripts 1 and 2 denote that the parton distributions in the proton as functions of x_1 and x_2 , respectively. In the case that $\overline{d} = \overline{u}$, the ratio is 1. This equation illustrates the sensitivity of the Drell-Yan measurement to $\overline{d}/\overline{u}$ and is valid only for $x_1 \gg x_2$. It does, however, imply an excess of \overline{d} with respect to \overline{u} for the data. Estimates of the nuclear effects in deuterium are significantly less than statistical errors shown in Fig. 1 [15].

Some of the data, especially at higher x_2 , do not satisfy the $x_1 \gg x_2$ criterion of Eq. (4). Consequently,

 $\overline{d}/\overline{u}$ was extracted iteratively by calculating the leading order Drell-Yan cross section ratio using a set of parton distribution functions as input and adjusting d/\bar{u} until the calculated cross section ratio agreed with the measured value. In this procedure, the values for the $\bar{d} + \bar{u}$, valence, and heavy quark distributions given by the global fits [e.g., CTEQ4M and MRS(R2)] were assumed to be correct. In the beam proton, when $x_1 \leq 0.345$, the \bar{d}/\bar{u} distribution was assumed to be the same as in the target proton. For $x_1 > 0.345$, a constant value of 1 for d/\bar{u} was used. Varying the high- x_1 value of \bar{d}/\bar{u} produced almost no change in the low x_2 bins, and less than a 3% change in the highest x_2 bin. This procedure was followed using both the CTEQ4M and MRS(R2) parametrizations and negligible differences were seen. The extracted \bar{d}/\bar{u} ratio is shown in Fig. 2 along with the prediction made by CTEQ4M. A qualitative feature of the data, not seen in either parametrization, is the rapid decrease towards unity of the d/\bar{u} ratio beyond x = 0.2. At x = 0.18, the extracted d/\bar{u} ratio is somewhat smaller than the value obtained by NA51. Although the average value of Q^2 $(M^2_{\mu^+\mu^-})$ is different for the two data sets, the change in $\frac{\tilde{d}}{\tilde{u}}$ predicted by the parton distributions due to \tilde{Q}^2 evolution is small.

To address the GSR violation observed by NMC, the extracted \bar{d}/\bar{u} ratio is used together with the CTEQ4M value of $\bar{d} + \bar{u}$ to obtain $\bar{d} - \bar{u}$. [Nearly identical results are obtained if MRS(R2) is used instead of CTEQ4M.] Since each bin in x has a different average Q^2 , $\bar{d} - \bar{u}$ was scaled to a common Q value of 7.35 GeV/c, the average for the entire data set. Based on this, the integral of $\bar{d} - \bar{u}$ between x^{\min} and 0.345 is calculated. Both $\bar{d} - \bar{u}$ and $\int_{x^{\min}}^{0.345} (\bar{d} - \bar{u}) dx$ are shown in Fig. 3. The integral

FIG. 2. The ratio of $\overline{d}/\overline{u}$ in the proton as a function of x extracted from the Fermilab E866 cross section ratio. The curve is from the CTEQ4M parton distributions. The error bars indicate statistical errors only. An additional systematic uncertainty of ± 0.032 is not shown. The result from NA51 is also plotted as an open box.

FIG. 3. Fermilab E866 values for (a) $\bar{d} - \bar{u}$ and (b) $\int_{x}^{0.345} (\bar{d} - \bar{u}) dx'$ in the proton versus x. The curves represent the corresponding values obtained by the CTEQ4M (solid line) and MRS(R2) (dashed line) parametrizations. The bar at 0.147 \pm 0.039 on the left axis in (b) shows the result obtained by NMC for the integral from 0 to 1.

reaches a value of $0.068 \pm 0.007(\text{stat}) \pm 0.008(\text{syst})$ at $x^{\min} = 0.02$. This may be compared with the CTEQ4M and MRS(R2) parametrizations which have values of 0.076 and 0.100, respectively, for the integral over the same region. Over the range $10^{-4} < x < 1$, CTEQ4M gives a value of 0.108 for the integral, and MRS(R2) gives 0.160. Above x = 0.345, it is unlikely that there are significant contributions to the $\overline{d} - \overline{u}$ integral since the sea is relatively small in this region. Both CTEQ4M and MRS(R2) find this region contributes less than 0.002 to the total integral. It is clear, however, that significant contributions to the integral arise in the unmeasured region below x = 0.02.

Such a large \bar{d}/\bar{u} asymmetry cannot arise from perturbative effects [16]. Most parametrizations of the parton distribution functions (e.g., CTEQ, MRS) simply assume a shape for $\bar{d} - \bar{u}$ that accommodates the NMC and NA51 results. It has been suggested [17,18] that including the effects of virtual mesons can account for the observed asymmetry, and this appears [19–22] to be at least qualitatively correct.

In summary, this Letter reports a measurement of the Drell-Yan cross section ratio per nucleon of p + d to p + p. From this measurement the asymmetry of the light quark sea in the proton is extracted as a function of x. A feature of the present result is the reduction in $\overline{d}/\overline{u}$ for x > 0.2. The current data are in qualitative agreement with NA51, but with a smaller $\overline{d}/\overline{u}$ ratio at the single value of x which they measured. Over the range of x covered in

this experiment (0.020 < x < 0.345), the integral of $\bar{d} - \bar{u}$ reaches a value of 0.068 ± 0.007 (stat) ± 0.008 (syst). However, contributions to the integral arise from the unmeasured region below x = 0.020.

We would like to thank the Fermilab Particle Physics, Beams and Computing Divisions for their assistance in performing this experiment. This work was supported in part by the U.S. Department of Energy.
