We construct stationary black-hole solutions in SU(2) Einstein-Yang-Mills theory which carry angular momentum and electric charge. Possessing nontrivial non-Abelian magnetic fields outside their regular event horizon, they represent nonperturbative rotating hairy black holes.

DOI: 10.1103/PhysRevLett.86.3704 PACS numbers: 04.70.Bw

*Introduction.*—Black holes in Einstein-Maxwell (EM) theory are completely determined by their mass, their charge, and their angular momentum, i.e., EM black holes have "no hair" [1,2]. The unique family of stationary asymptotically flat EM black-hole solutions comprises the rotating charged Kerr-Newman (KN) solutions, the static charged Reissner-Nordstrøm solutions, the rotating Kerr solutions, and the static Schwarzschild solutions. Besides the "no-hair" theorem, Israel's theorem holds in EM theory, stating that static black holes are spherically symmetric.

Both theorems cannot be extended to theories with non-Abelian gauge fields [3,4]. While the first classical "hairy" black-hole solutions found are static and spherically symmetric [3], recently also static black-hole solutions with only axial symmetry have been constructed [5,6], as well as static (perturbative) black-hole solutions without rotational symmetry [7].

Evidently, also rotating hairy black-hole solutions should exist [8]. The construction of such solutions, however, has represented a difficult challenge. In particular, the usual parametrization of the stationary axially symmetric metric [9] has been considered as possibly too narrow for non-Abelian solutions [10–12], and furthermore, even the usual parametrization leads to a highly involved set of differential equations, to be solved numerically. Therefore, stationary generalizations of the static spherically symmetric SU(2) Einstein-Yang-Mills (EYM) black-hole solutions [3] have previously only been considered perturbatively [10,13].

Here we construct the first set of nonperturbative rotating non-Abelian black-hole solutions. Considering SU(2) EYM theory as well, we obtain hairy black-hole solutions which are asymptotically flat and possess a regular event horizon. Similar to their perturbative counterparts [10], these hairy black-hole solutions carry both angular momentum and electric charge.

*Embedded Kerr-Newman black holes.*—We consider the SU(2) EYM action

$$
S = \int \left( \frac{R}{16\pi G} - \frac{1}{2} \text{Tr}(F_{\mu\nu} F^{\mu\nu}) \right) \sqrt{-g} \, d^4x \,, \quad (1)
$$

with  $F_{\mu\nu} = \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu} + ie[A_{\mu}, A_{\nu}], \qquad A_{\mu} =$  $1/2\tau^a A^a_\mu$ , and *G* and *e* are Newton's constant and the Yang-Mills coupling constant, respectively. Variation with respect to the metric and the matter fields leads to the Einstein equations and the field equations, respectively.

We first note that Kerr-Newman black holes may be embedded in SU(2) EYM theory [14]. For a Kerr-Newman black hole with mass *M*, angular momentum  $J = aM$  and "total charge" *Q*, where  $Q^2 = Q^a Q^a + P^a P^a$  [15,16], the metric in Boyer-Lindquist coordinates is given by

$$
ds^{2} = -\frac{\Delta}{\rho^{2}}(dt + a\sin^{2}\theta d\varphi)^{2} + \frac{\sin^{2}\theta}{\rho^{2}}(adt + \rho_{0}^{2}d\varphi)^{2}
$$

$$
+ \frac{\rho^{2}}{\Delta}d\tilde{r}^{2} + \rho^{2}d\theta^{2},
$$
(2)

with

$$
\rho^{2} = \tilde{r}^{2} + a^{2} \cos^{2} \theta, \qquad \rho_{0}^{2} = \tilde{r}^{2} + a^{2},
$$
  
 
$$
\Delta = \tilde{r}^{2} - 2M\tilde{r} + a^{2} + Q^{2}, \qquad (3)
$$

and the gauge field is given by

$$
A_{\mu}^{a}dx^{\mu} = \frac{Q^{a}\tilde{r}}{\rho^{2}}(dt + a\sin^{2}\theta d\varphi)
$$

$$
+ \frac{P^{a}\cos\theta}{\rho^{2}}(adt + \rho_{0}^{2}d\varphi). \tag{4}
$$

The condition  $\Delta(\tilde{r}_H) = 0$  yields the regular event horizon of the Kerr-Newman solutions,  $\tilde{r}_H = M +$  $M^2 - (a^2 + Q^2).$ 

*Ansatz for hairy black holes.*—Proving to be adequate, we employ the usual parametrization of the metric [9] to obtain rotating hairy black-hole solutions. In isotropic coordinates the metric reads

$$
ds^{2} = -fdt^{2} + \frac{m}{f}[dr^{2} + r^{2}d\theta^{2}]
$$

$$
+ \sin^{2}\theta r^{2} \frac{l}{f}[d\varphi + \frac{\omega}{r}dt]^{2}, \qquad (5)
$$

where  $f$ ,  $m$ ,  $l$ , and  $\omega$  are functions of only  $r$  and  $\theta$ . This ansatz satisfies the circularity and Frobenius conditions [2,9,17]. For the gauge potential we choose the ansatz

$$
A_{\mu}dx^{\mu} = \Phi dt + A_{\varphi}\left(d\varphi + \frac{\omega}{r}dt\right)
$$

$$
+ \left(\frac{H_1}{r}dr + (1 - H_2)d\theta\right)\frac{\tau_{\varphi}}{2e}, \quad (6)
$$

with

$$
A_{\varphi} = -\sin\theta \left[ H_3 \frac{\tau_r}{2e} + (1 - H_4) \frac{\tau_\theta}{2e} \right],
$$
  
\n
$$
\Phi = B_1 \frac{\tau_r}{2e} + B_2 \frac{\tau_\theta}{2e},
$$
\n(7)

where the symbols  $\tau_r$ ,  $\tau_\theta$ , and  $\tau_\varphi$  denote the dot products of the Cartesian vector of Pauli matrices with the spherical spatial unit vectors (e.g.,  $\tau_r = \tau_x \sin\theta \cos\varphi + \tau_y \sin\theta \cos\varphi$  $\tau_v$  sin $\theta$  sin $\varphi + \tau_z \cos \theta$ , and the gauge field functions *H<sub>i</sub>* and  $B_i$  depend on only r and  $\theta$ .

With respect to the residual gauge degree of freedom [5] we choose the gauge condition  $r \partial_r H_1 - \partial_\theta H_2 = 0$ .

*Boundary conditions.*—To obtain stationary axially symmetric black-hole solutions which are asymptotically flat, and possess a regular event horizon, as well as a finite mass, angular momentum, and electric charge, we need to impose the appropriate set of boundary conditions.

The condition  $f(r_{\rm H}) = 0$  determines the event horizon [18]. Regularity of the event horizon then requires the boundary conditions  $f = m = l = 0$ ,  $\omega = \omega_H = \text{const}$ ,  $H_1 = 0$ ,  $\partial_r H_2 = \partial_r H_3 = \partial_r H_4 = 0$ ,  $r_H B_1 + \cos \theta \omega_H = 0$ ,  $r_{\rm H}B_2$  –  $\sin\theta\omega_{\rm H}$  = 0, for  $r = r_{\rm H}$ ,  $\theta \in [0, \pi]$  (with the gauge condition  $\partial_{\theta}H_1 = 0$  taken into account).

The boundary conditions at infinity are  $f = m = l = 1$ ,  $\omega = 0$ ,  $H_1 = H_3 = 0$ ,  $H_2 = H_4 = \pm 1$ , and  $B_1 =$  $B_2 = 0$ . The boundary conditions on the symmetry axis  $(\theta = 0)$  are  $\partial_{\theta} f = \partial_{\theta} l = \partial_{\theta} m = \partial_{\theta} \omega = 0$ ,  $H_1 = H_3 =$  $B_2 = 0$ ,  $\partial_{\theta}H_2 = \partial_{\theta}H_4 = \partial_{\theta}B_1 = 0$ , and agree with the boundary conditions on the  $\theta = \pi/2$  axis, except for  $B_1 = 0, \ \partial_{\theta} B_2 = 0.$ 

*Properties of the solutions.*—The global charges of the black-hole solutions are determined from their asymptotic behavior. In particular, expansion at infinity yields [19]

$$
f \to 1 - \frac{f_{\infty}}{r}, \qquad \omega \to \frac{\omega_{\infty}}{r^2}, \qquad B_1 \to \frac{B_{\infty} \cos \theta}{r},
$$

$$
B_2 \to \frac{B_{\infty} \sin \theta}{r}, \qquad (8)
$$

determining the mass  $M = \frac{1}{2} \lim_{r \to \infty} r^2 \partial_r f$ , the angular momentum  $J = \frac{1}{2} \lim_{r \to \infty} r^2 \omega$  and the electric charge  $Q =$  $B_{\infty}/e$ , which we read off in a gauge where  $\Phi \to \frac{\bar{B}_{\infty}}{r}$  $\frac{\tau_z}{2e}$ .

Of interest are also the properties of the horizon. The surface gravity is obtained from [9]

$$
\kappa_{\rm sg}^2 = -1/4(D_{\mu} \chi_{\nu}) (D^{\mu} \chi^{\nu}), \qquad (9)
$$

where the Killing vector  $\chi = \xi - (\omega_H/r_H)\eta$  ( $\xi = \partial_t$ ,  $\eta = \partial_{\varphi}$ ) is orthogonal to and null on the horizon. Expansion near the horizon in  $\delta = (r - r_H)/r_H$  yields to lowest

order  $f = \delta^2 f_2(\theta)$ ,  $m = \delta^2 m_2(\theta)$  [20], and thus the surface gravity

$$
\kappa_{\text{sg}} = \frac{f_2(\theta)}{r_{\text{H}}\sqrt{m_2(\theta)}},\tag{10}
$$

which by the zeroth law of black-hole mechanics is required to be constant on the horizon.

We further consider the area *A* of the black-hole horizon, defining the area parameter  $r_{\Delta}$  via  $A = 4\pi r_{\Delta}^2$ , and the deformation of the horizon, quantified by the ratio  $L_e/L_p$ of the circumferences along the equator and the poles.

We have checked that for our numerical solutions the surface gravity is indeed constant and the Kretschmann scalar is finite at the horizon [20].

*Numerical results.*—We solve the set of ten coupled nonlinear elliptic partial differential equations numerically, subject to the above boundary conditions, employing compactified dimensionless coordinates,  $\bar{x} = 1 - (x_H/x)$ with  $x = \frac{e}{\sqrt{4\pi G}}r$ .

The numerical calculations are performed with the program FIDISOL [21], based on the Newton-Raphson method. Starting from an initial configuration, corrections are calculated successively, until the numerical solution satisfies a given tolerance for the relative error, typically  $10^{-3} - 10^{-4}$ .

The solutions depend on one discrete parameter, the node number *n* of the gauge field, and on two continuous parameters, the isotropic horizon radius  $x_H$  and the value of the metric function  $\omega$  at the horizon,  $\omega_H$ , where  $\omega_H/x_H$ represents the rotational velocity of the horizon.

As an initial guess we employ the static spherically symmetric SU(2) EYM black-hole solution with horizon radius  $x_H$  and one node, corresponding to  $\omega_H = 0$  [22]. Increasing  $\omega_H$  leads to rotating black-hole solutions with nontrivial functions  $\omega$ ,  $B_1$ ,  $B_2$ ,  $H_1$ , and  $H_3$ , whose mass  $M$ , electric charge *Q*, and angular momentum *J* are determined from their asymptotic behavior [see Eq. (8)].

FIG. 1. The dimensionless mass  $\mu$  of the rotating non-Abelian black-hole solutions is shown on the lower branch (solid line) and upper branch (dashed line) as a function of the parameter  $\omega_H$  for the horizon radius  $x_H = 1$ . Also shown are the angular momentum per unit mass  $a = J/\mu$  and the charge *Q*. For comparison  $\mu$  and *a* of the Kerr solution ( $Q = 0$ ) for  $x_H = 1$ are also shown (dotted line).

FIG. 2. The surface gravity  $\kappa_{sg}$  of the rotating non-Abelian black-hole solutions is shown on the lower branch (solid line) and upper branch (dashed line) as a function of the parameter  $\omega_H$ for the horizon radius  $x_H = 1$ . Also shown are the area parameter  $x_{\Delta}$  and the deformation, as quantified by the ratio of circumferences  $L_e/L_p$ . For comparison  $\kappa_{sg}$ ,  $x_{\Delta}$  and  $L_e/L_p$  of the Kerr solution ( $Q = 0$ ) for  $x_H = 1$  are also shown (dotted line).

As we increase  $\omega_H$  from zero, while keeping  $x_H$  fixed, a first branch of solutions forms, the lower branch. This branch extends up to a maximal value of  $\omega_H$ , which depends on  $x_H$ . There a second branch, the upper branch, bends backwards towards  $\omega_H = 0$ . Along both branches mass, electric charge, and angular momentum continuously increase, as seen in Fig. 1, where the dimensionless mass  $\mu = (e/\sqrt{4\pi G})GM$ , the electric charge *Q*, and the angular momentum per unit mass  $a = J/\mu$  are shown as functions of  $\omega_H$  for  $x_H = 1$ .

The presence of two branches is no surprise. Indeed, also the KN and Kerr solutions exhibit two branches, when considered as functions of  $\omega_H$  for fixed isotropic horizon radius  $x_{\text{H}}$ .

Whereas both mass  $\mu$  and angular momentum per unit mass *a* of the non-Abelian solutions increase strongly along the upper branch, diverging with  $\omega_H^{-1}$  in the limit  $\omega_H \rightarrow 0$ , their electric charge Q remains small. For comparison, we therefore show in Fig. 1 also  $\mu$  and  $a$  of the corresponding Kerr solutions ( $Q = 0$ ) for  $x_H = 1$ , which satisfy  $\frac{\omega_H}{x_H} = \left[\sqrt{\mu^2 - 4x_H^2}/2\mu(\mu + 2x_H)\right]$ . The Kerr solutions exist up to a slightly higher value of  $\omega_H$ . Along the

FIG. 3. The energy density  $-T_0^0$  of the rotating non-Abelian black-hole solutions is shown on the lower branch for  $\omega_H =$ 0.05 and horizon radius  $x_H = 1$ . Also shown are the event horizon (solid line) and the static limit (dashed line), enclosing the ergosphere.

upper branch, the non-Abelian fields become less important, and the solutions tend towards extremal Kerr (KN) solutions in the limit  $\omega_H \rightarrow 0$ .

In Fig. 2 we show the surface gravity  $\kappa_{sg}$  for  $x_H = 1$ as a function of  $\omega_H$ , as well as the area parameter  $x_\Delta$  and the deformation of the horizon, quantified by  $L_e/L_p$ . As a typical example of a rotating hairy black-hole solution, we show in Fig. 3 the energy density  $-T_0^0$  (of the gauge fields) for isotropic horizon radius  $x_H = 1$  and  $\omega_H =$ 0.05. Properties of this solution are shown in Table I, and compared to the corresponding Kerr values.

In Fig. 4 we show the mass  $\mu$  of the non-Abelian blackhole solutions as a function of the isotropic horizon radius  $x_H$  for several fixed values of  $\omega_H$ . For a given value of  $\omega_H$  there is a minimum value of the horizon radius  $x_H$ . In particular, the limit  $x_H \rightarrow 0$  is reached only for  $\omega_H \rightarrow 0$ . Thus we do not obtain globally regular rotating solutions in the limit  $x_H \rightarrow 0$  [10]. This is to be expected, since globally regular rotating solutions should satisfy a different set of boundary conditions at infinity [13].

For comparison, we have included in Fig. 4 the mass  $\mu$ of the corresponding Kerr black-hole solutions. For a fixed value of  $\omega_H$ , the Kerr solutions form two straight lines, extending from the origin. The non-Abelian solutions tend toward these lines for large values of the horizon radius.

TABLE I. The dimensionless mass  $\mu$ , the charge Q, the angular momentum per unit mass  $a = J/\mu$ , the surface gravity  $\kappa_{sg}$ , the area parameter  $x_{\Delta}$ , and the ratio of circumferences  $L_e/L_p$  of the rotating non-Abelian black-hole solutions are shown for the values  $\omega_H = 0.01$ , 0.02, and 0.05 and horizon radius  $x_H = 1$ . For comparison the values of the corresponding Kerr solutions ( $Q = 0$ ) are also shown.

	$\omega_{\text{H}} = 0.01$		$\omega_{\text{H}} = 0.02$		$\omega_{\rm H} = 0.05$	
	EYM	Kerr	EYM	Kerr	EYM	Kerr
$\mu$	2.23	2.01	2.25	2.03	2.46	2.20
$\varrho$	$0.233 \times 10^{-2}$	$\Omega$	$0.474 \times 10^{-2}$	$\Omega$	$1.35 \times 10^{-2}$	0
a	0.18	0.16	0.365	0.321	1.051	0.927
$\kappa$	0.112	0.124	0.110	0.122	0.095	0.108
$x_{\Delta}$	4.23	4.01	4.26	4.04	4.58	4.31
$L_e/L_p$	1.0013	1.0012	1.0055	1.0049	1.0412	1.0361

FIG. 4. The dimensionless mass  $\mu$  of the rotating non-Abelian black-hole solutions is shown on the lower branch (solid line) and upper branch (dashed line) as a function of the horizon radius  $x_H$  for the values of the parameter  $\omega_H = 0.01, 0.02$ , 0.05. For comparison for the same values, the mass of the Kerr solution  $(Q = 0)$  is also shown (dotted line).

To compare with the perturbative calculations, where linear rotational excitations of the static EYM black holes were studied, we consider the limit  $\omega_H \rightarrow 0$  along the lower branch. In the perturbative calculations  $Q \propto J$  [10], and the ratio  $Q/J$  depends only on the horizon radius. The nonperturbative calculations show good agreement with the perturbative results for small values of  $\omega_H$  (on the lower branch) and large values of the horizon radius. For small values of the horizon radius, significant deviations arise.

Further details of these rotating non-Abelian black-hole solutions as well as the presentation of the rotating higher node solutions will be given elsewhere [20].

Beside these non-Abelian stationary charged black-hole solutions with finite angular momentum *J* and finite electric charge *Q*, the perturbative studies [13] have revealed two more types of stationary non-Abelian black-hole solutions, namely, rotating black-hole solutions which are uncharged  $(J > 0, Q = 0)$ , and nonstatic black-hole solutions, which have vanishing angular momentum  $(J = 0)$ ,  $Q \neq 0$ ). Both types satisfy a different set of boundary conditions at infinity. Construction of their nonperturbative counterparts remains open, as well as the possible existence of rapidly rotating branches of non-Abelian black-hole solutions, not connected to the static solutions.

By including dilaton and axion fields, finally, further interesting rotating hairy black holes should be generated, representing new solutions of the low energy effective action of string theory.
